INSTITUTE OF ENERGY
FOR SOUTH-EAST EUROPE

The Institute of Energy for South East Europe (IENE)

The Institute of Energy for South East Europe (IENE) was founded in 2003 by a small group of independent professionals and business executives active in the energy sector of the region. The Institute, which has its headquarters in Athens, Greece, is a non-governmental and nonprofit organization. The Institute's prime purpose is to constitute a permanent forum where energy issues can be discussed, analyzed, reformulated and presented to a broader audience, in unbiased, objective and credible terms. This is achieved thanks to the Institute's scientific standing, its managerial rectitude and the transparency of all its operations.

The Institute activities span all forms of energy including hydrocarbons, solid fuels, electricity, emissions, nuclear, renewables, energy efficiency and energy technologies. The Institute is largely funded from its membership which includes both corporate entities and individual energy professionals.

One of IENE's key objectives is to participate in the formulation of energy policies, both at national and international level, within the broader region of South-East Europe. These policies focus on rationalizing the production and utilization of both conventional and renewable sources of energy. IENE is thus contributing towards the implementation of the European Union's sustainable strategy which combines social and economic development, security of supply and environmental protection. The Institute aspires to play a significant role in providing factual and unbiased information to professionals and to a broader audience alike on subjects concerning energy, the environment and sustainable development. Through an expansion of its partnership base in 2020/2021 IENE is now representing 13 counties of the region and can be truly regarded as a regional entity. Further information on the Institute, its mission, its objectives and its activities can be found in **www.iene.eu**

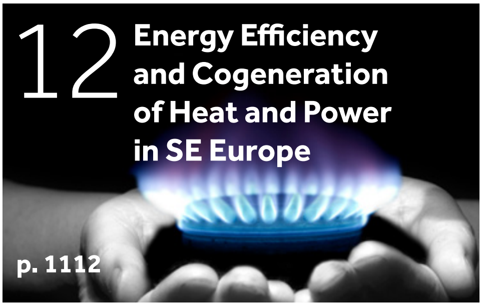
Summary of Contents



Contents

* Throughout this Study, this designation is without prejudice to positions on status, and is in line with UNSCR 1244 and the ICJ Opinion on the Kosovo declaration of independence.

Acknowledgements

Several people have worked to make this study happen and therefore deserve a fair mention. Indeed, all study contributors, authors, peer reviewers and support staff are fully listed and acknowledged in the appropriate sections of the report. I wish to sincerely thank all of them for their most valuable input.

Special thanks go to Mr. Dimitris Mezartasoglou, who in addition to being a key study contributor acted as Associate Editor, often facilitating me through his timely intervention and tireless work in compiling and sorting out what at times appeared to be a mountain of papers and a meander of electronic files. In addition to the above and as project coordinator I wish to acknowledge with thanks the continuous encouragement and moral support provided by IENE's past Chairman Mr. John Chadjivassiliadis, a Peer Reviewer himself and by Mr. Christos Dimas, an IENE partner and Chairman of IENE's Geopolitical Committee who also acted as Peer Reviewer. Special thanks also go to Ms. Mary Mavrogeni in charge of IENE's accounts department. She helped me selflessly and in a very determined way to overcome several hurdles in the arduous path of raising the necessary funding which allowed the realization and publication of the study.

Finally, I want to sincerely thank all IENE staff who work in our offices in Athens for their important contribution and patience in dealing with my endless information requests and pressing communication demands.

Costis Stambolis

Executive Director, Institute of Energy for SE Europe (IENE)

Preface

The present "Energy Outlook" study for South East Europe is the third of its kind to be published by IENE in the space of a decade, signifying the Institute's strong commitment to a comprehensive approach when it comes to examining the region's diverse energy landscape. The first embryonic 'Outlook' study was released in the summer of 2011 and the second, far better organised with enriched content and a broader team of contributors was published in May 2017.

Now, following almost two years of intense preparation the third edition of the "SEE Energy Outlook", dated 2021/2022, is out and contains a compendium of facts and a review of latest activities backed by exhaustive data and analysis on the energy situation in the region. The publication would have been published 12 months ago but COVID-19 related complications in data collection and in the analysis phase prevented the IENE team from moving much faster. Despite the delay the 'Outlook' is still timely as several of the major energy issues discussed and presented, such as electricity and gas market integration, electricity and gas grid expansion, the higher penetration of renewables in the energy mix, the region's decarbonisation process, improvement in energy efficiency and the increasingly important role of technology are still very relevant, and hence a discussion backed by detailed data is most timely.

Because of the considerable delay experienced in producing this work with most country profiles submitted by the summer of 2020 energy data from most countries uses 2018 as a reference year. In several cases we have managed to include latest data covering 2019 and 2020. When it comes to electricity and gas prices and in view of major market anomalies experienced in the second half of 2021, we have included a whole Addendum to the Electricity section (See Chapter 10) where all latest moves on prices are discussed.

The present edition of the "SEE Energy Outlook" is expanded in terms of content compared to the last edition, as it includes profiles of two more countries and one extra sector (technology). So, a total of 15 countries from the broader region are covered through dedicated Country Profiles with several well researched topic areas also included. The inclusion of Hungary and Israel in the present 'Outlook' edition completes our informed energy perspective of the region, in the sense that Hungary over the last few years has emerged as key regional electricity hub for SEE, while Israel which has of late become an important gas producer is already impacting energy flows in the region.

The great bulk of the Outlook's content is original in concept and writing and is based on contributions from 29 experts from all different countries in the region and their names and CV's appear in the first pages of the Outlook. Of great importance too is the work undertaken by the Peer Reviewers whose names and brief biodata is also included. Tremendous effort was also made by the Institute's in-house research team who had to accommodate work on this project with a busy schedule related to analysis work, ongoing surveys, project assessment and the preparation of IENE's regular information feed to its members. It is going without saying that both myself and the Institute are much indebted to them for their enthusiasm and commitment in undertaking and completing under duress the agreed assignments.

Funding for the preparation and publication of this voluminous work came from a group of 16 energy companies who acted as sponsors and supporters,mostly from Greece but also from Bulgaria and Turkey. It is fair to say that without their valuable support and generosity publication of this 'Outllook' study would not have materialised. On behalf of IENE I sincerely wish to thank them for entrusting the Institute and for actively supporting this project, which in essence is a truly regional collaborative effort, culminating in what turned out to be a major reference study.

Executive Summary
By the IENE Team

Chapter 1
Introduction
Costis Stambolis, Executive Director IENE, Outlook Editor

Chapter 2
Regional Economic Outlook
Dimitris Mezartasoglou, Research Fellow IENE

Chapter 3
EU Energy and Environmental Policies and Regional Priorities
Dimitris Mezartasoglou

Chapter 4
Key Regional Energy Issues
Costis Stambolis
Dimitris Mezartasoglou

Chapter 5
Country Profiles

Albania
- Shkelqim Bozgo, Managing Partner, SEA-Consulting, Albania
- Abaz Aliko, Founding Member, SEA-Consulting, Albania

Bosnia and Herzegovina
Mirsad Sabanovic, Director, ASA Energija, Bosnia and Herzegovina

Bulgaria
Kaloyan Staykov, Chief Economist, Energy Management Institute (EMI), Bulgaria

Croatia
Robert Bosnjak, Energy Expert, EIHP, Croatia

Cyprus
Anthi Charalambous, Director of Energy & Environment, Cyprus Employers & Industrialists Federation (OEB), Nicosia, Cyprus

Greece
Dimitris Mezartasoglou

Hungary
Adam Balogh, MBA, Senior Energy Infrastructure Expert, Energy Community, Austria

Israel
- Gina Cohen, Consultant to the Natural Gas Market and Lecturer at Technion University, Israel
- Miki Korner, Chief Economist at MNI, Israel

Kosovo
Fadil Ismajli, CEO, New Kosovo Electricity Company (NKEC), Kosovo

Montenegro
Aleksandar Mijuskovic, Chairman of the BoD, CGES, Montenegro

North Macedonia
Vesna Borozan, Professor of Power Systems, University "Sts. Cyril and Methodius", Faculty of Electrical Engineering and Information Technologies, North Macedonia

Romania
Eugenia Gusilov, Director, Romania Energy Center (ROEC), Romania

Serbia
Mihailo Mihailovic, Independent Energy Consultant, former Head of PE Electric Power Industry of Serbia, Serbia

Slovenia
Matjaz Cesen, Advisor, Jozef Stefan Institute, Slovenia

Turkey
Yurdakul Yigitgüden, Independent Energy Consultant, (F) Co-ordinator of OSCE Economic and Environmental Activities, (F) Under-Secretary of Energy and Natural Resources, Turkey

Chapter 6

The Peripheral Countries

Dimitris Mezartasoglou

Chapter 7

The Legal Framework of the Energy Market in SE Europe

- Gus Papamichalopoulos, Senior Partner, Head of Energy, Utilities & Infrastructure, KG Law Firm, Greece
- Anna-Maria Papamichalopoulou, Junior Associate, Energy, Utilities & Infrastructure, KG Law Firm, Greece

Chapter 8

Hydrocarbon Exploration and Production in SE Europe

Dr. Yannis Bassias, Energy Consultant, former Chairman and CEO, Hellenic Hydrocarbon Resources Management (HHRM), Greece

Chapter 9

The Oil and Gas Sector

9.1 Oil Midstream and Downstream

- Irene Terzidou, Research Fellow IENE, Greece

9.2 Gas Market

- Alexandros Koutroumpousis, Director of Large & Medium Business Customers at PPC S.A., Former Head of Energy Markets at DEPA, Greece

Chapter 10

The Electricity Sector

Alexandros Perellis, Research Fellow IENE, Greece

Chapter 11

Renewable Energy Sources

Nikos Sofianos, Independent Energy Consultant, Research Associate IENE, Chairman of IENE's RES Committee, Greece

Chapter 12

Energy Efficiency and Cogeneration of Heat and Power in SE Europe

Costas Theofylaktos, Secretary General IENE, Chairman of IENE's Energy Efficiency Committee, Greece

Chapter 13

Energy Technology Perspectives in SE Europe

- Costis Stambolis
- Dimitris Mezartasoglou

Chapter 14

Energy Demand and Supply Projections for SE Europe

- Dr. George Giannakidis, Senior Energy Consultant, Greece
- Rocco DeMiglio, Energy Systems Analyst and Modeler, Italy
  Energy Consultant, Greece

Chapter 15

Investment Potential in the Energy Sector of SE Europe

- Dimitris Bimpas, Scientific Advisor at Economic and Social Council of Greece (OKE), Greece
- Dimitris Mezartasoglou
- Costis Stambolis

Chapter 16

Key Messages

By the IENE Team

Contributor Resumes

Dr. Abaz Aliko

Dr. Abaz Aliko is a senior economist with a strong academic background. He has been Commissioner at the Albanian energy regulator Director at the Albanian Central Tax Authority active member of high local government bodies lecturer of a few universities as well as freelance financial and business consultant and is actually a partner of SEA Consulting. His area of expertise include: Identification and assessment of business cases in the area of RES and power sector Energy sectorregulation pricing and tariff methodologies and their practical implementation. Determination of the allowed expenses for the regulated tariffs of the regulated companies in the energy sector. Review of the investment plans of regulated companies.Market model of the electricity sector. Market rules network codes and connections to the greed. Capacity allocation contracts for different market participants.Review and development of PowerSector acts including natural gas and renewables. Support schemes for renewables. Analysis of long-term developments in the sector and possible options. In depth knowledge of the tax syste. Lecturing on economics and finance. Strong negotiation skills. Mr. Aliko was born in Gjirokastra Albania. He has a Ph.D. in economics and agriculture policy by the Agriculture University of Tirana.

Adam Balogh

Adam Balogh has an MA in economics from the University of Szeged in Hungary and an MBA specialised in energy, from the Vienna University of Economics, Austria. Currently he is a senior energy infrastructure expert at the Energy Community Secretariat in Vienna, Austria, where he deals with the socio-economic assessment of large gas infrastructure projects, potential of hydrogen technologies and energy legislation and regulation. Previous positions of Adam include: Adviser - European Network of Transmission System Operators for Gas – ENTSOG in Brussels, dealing with the European Ten Year Network Development Plan and projects' Cost-Benefit Analysis; Business Development Expert - FGSZ Ltd., the Hungarian Gas TSO, Controller - Exxon Mobil

Dr. Yannis Basssias

Dr. Yannis Basssias has 35 years of experience in the international oil and gas industry. From 2016 to 2020, he served the Greek State as President & CEO of HHRM (Hellenic Hydrocarbon Resources Management), handling the oil & gas E & P activities and supervising the offshore safety regulations. He was member of the National Commttee of Energy and Climate (ESEK) policy group of Greece in 2018 and 2019 and since 2021 he assists municipalities in West Macedonia in their decarbonisation plans and is also involved in the LNG area. From 2012 to 2016, he advised international companies in the EEZs of the Indian Ocean, Equatorial America and West Africa on geological and legal aspects of frontier hydrocarbon basins. From 1991 to 2012, as CEO and president of the group Georex, he demerged the hydrocarbon assets from the service activities of the group establishing technical subsidiaries in France, United Kingdom, Tunisia and the Republic of Congo. He handled upstream projects for the CIS, Total, Elf, SNPC and Esso and between 1996 and 2000 he directed evaluation teams for oil and gas interests in Texas and Colombia. Before joining the petroleum industry, from 1985 to 1991, Mr. Bassias had an academic career at the Free University of Berlin and then as Associate Professor in the Marine Geology Department of the National Museum of Natural History in Paris focusing in the Indian Ocean petroleum bearing basins. He graduated from the Kapodistrian University in Athens, he holds a PhD in geology from the University of P. & M. Curie in Paris and has studied in Management-Negotation and Corpoarte Financing in Paris.

Dimitris Bimpas

Dimitris Bimpas is an economist. Currently he is scientific advisor, at the Economic and Social Council of Greece (OKE), and he is also a member of the experts' network of the Academy Avignon for Crafts and SMEs He has worked as Research Associate, and Economist, at the Division of Economic Analysis & SMEs, at the Small Enterprise's Institute (IME) of GSEVEE. He has been a Scientific advisor to the General Secretariat of the Ministry of Development of Hellenic Republic where he specialized on SMEs policies, strategic investments, sustainable development, health care policies and health tourism. He also contributes regularly to IENE projects where he holds the position of Research Fellow. He holds a BSc in Economics (University of Macedonia, Thessalonica), an MSc in Economic and Social Policy Analysis (University of York, UK), and an MPhil in Economic Sciences (National and Kapodistrian University, Athens).

Stefan Borozan

Stefan Borozan received his BSc degree in Electrical Engineering and Information Technologies from Ss. Cyril and Methodius University in Skopje, North Macedonia, in 2017, and his MSc degree in Future Power Networks from Imperial College London, United Kingdom, in 2018. Since then, he has continuously held a position as a visiting research associate in the Faculty of Electrical and Electronic Engineering in Skopje, and in 2019 he worked as a New Customer Connections Project Manager at the largest distribution system operator in North Macedonia, Elektrodistribucija DOOEL (part of EVN Group). Currently, he is a researcher in the Department of Electrical and Electronic Engineering at Imperial College London, working towards the PhD degree.

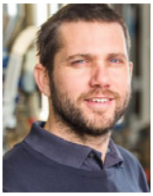
Robert Bosnjak

Over twenty years, Robert Bosnjak has been actively involved in gas market development projects in South East Europe dealing with energy consumption and gas and heat system development aspects: Energy consumption analyses, Energy consumption forecasting, gas and heat network development projects planning, pre-feasibility and feasibility studies development. Soon after gaining a Master's degree in petroleum engineering Robert was employed in Energy Institute Hrvoje Pozar in Croatia. He left the Institute from the Deputy Head of Energy Systems Planning Department position. Currently, Mr Bosnjak holds a position as Head of Strategic Development Department in Plinacro, the Croatian gas TSO. During his professional carrier he participated in several advanced trainings of which the FOIP – business and company development – Preparation and evaluation of investment projects, RUHRGAS Gas Distribution System Planning Software and Market Research, Information and Optimisation System training, IAEA expert MAED – Model for Analysis of Energy demand training and ENERDATA s.a. in France. Demand Forecasting and Energy Efficiency Evaluation are the most important training seminars which he attended.

Shkëlqim Bozgo

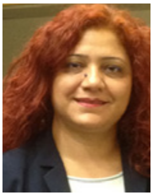
Shkëlqim Bozgo is a petroleum engineer and senior executive with nearly three decades of work experience mostly managing large and medium size commercial and non-for profit organizations in complex and multicultural environments. He has rich experience in the energy sector and particularly with the emerging natural gas markets and infrastructure in Albania, Kosovo and the Energy Community region. As member of the Board of Commissioners he has lead the Albanian Energy Regulator's work in the joint process of the Energy Regulators of Greece (RAE), Italy (ARERA) and Albania (ERE) for awarding the conditional exemption from the third party access to the natural gas interconnector Trans Adriatic Pipeline (TAP). He is the author of several regulatory documents and pre-feasibility studies for the Albanian and Kosovo natural gas sector and remains active with the natural gas sector developments issues in the Energy Community and wider. Shkëlqim has also extensive international experience including PSA negotiations with IOC, implementation of EU funded projects and as the ERE representative in the Energy Community Regulatory Board and its elected President (2012-2013). He was the Albania Country Manager of the mega project Trans Adriatic Pipeline and is currently the Managing Partner of SEA-Consulting.

Matjaz Cesen



Matjaz Cesen, has a BsC in Meteorology, and he is a researcher at the Jozef Stefan Institute – Centre for Energy Efficiency. His research interests are particularly related to energy consumption and supply modelling and simulation and emissions modelling, analysis of statistical data, energy indicators, decomposition analysis, statistical analysis and climate, air pollution and energy policy decision support methods. He has actively participated in research projects related to energy modelling, emissions modelling, analysis of energy consumption in households and transport, evaluation of effect of different measures on energy consumption and emissions, evaluation of proposed targets for Slovenia and their potential for their achievement and review of emission inventories. He also participated in the review of national communications and biennial reports under UNFCCC. He is also a lead reviewer and in several EU projects.

Anthi Charalambous



Anthi Charalambous is a Chemical Engineer having graduated from the National Technical University of Athens (NTUA), with specialization in Environmental Engineering (MSc). She also holds a Masters in Business Administration (MBA) and P.Dip. in Renewable Energy and Energy Management. At the beginning of her career (1997) she worked abroad in environmental projects, environmental impact assessment studies, in the management and processing of liquid and solid wastes and in designing biomass to energy plants. In 2001 she started working in the field of renewable energy and energy saving at the Cyprus Institute of Energy and in 2004 she was appointed Energy Attaché in the Permanent Representation of Cyprus at the EU in Brussels. In 2007 she joined the European Commission's Directorate-General for Energy (DG ENER) working in the renewable energy technologies Unit. During 2009 – 2015 she was the Director of the Cyprus Energy Agency. She has participated in many conferences in Cyprus and abroad as an invited speaker and she has published widely on RES and Energy Efficiency. She was the Secretary of the Cyprus Association of Chemical Engineers for the period 2010-2012 and a member of the Committee on Energy Policy in the Scientific and Technical Chamber of Cyprus (ETEK) for the period 2009-2014. In 2016 she joined the Cyprus Employers and Industrialists Federation (OEB) as the Head of the Energy & Environment Division.

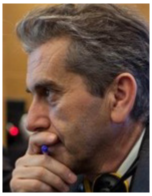
Dr. Gina Cohen

Dr. Gina Cohen has been working as a natural gas analyst and consultant in the Eastern Mediterranean for more than two decades, with a focus on Israel, Jordan, Cyprus, Turkey, Egypt and the Palestinian Authority.During her many years of work in the energy sector, she has been involved in projects spanning the full natural gas chain: from exploration & development, gas legislation and regulation, Gas Sales and Purchase negotiations, independent power generation and FLNG projects, permitting for the Israeli gas offshore facilities, etc. Gina is a lecturer at the graduate school for Petroleum Engineers at the Technion University in Israel and at Cyprus University Department of Civil and E nvironmental Engineering, and often speaks in many international gas conferences. Gina Gohen is the author of the energy lexicon (www.hebrewenergy.com) and a book published by IENE entitled "Long Term Gas Contracting".

Rocco De Miglio

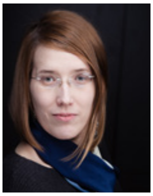
Rocco De Miglio is an Industrial and Management Engineer, with extensive experience in the development of decision support system tools, in the application of different modelling techniques, and in the preparation and analysis of energy-climate strategies and plans. He works as an individual Senior International Expert for consulting services and technical assistance on energy-climate analyses and on modelling activities (he has experience in several EU Member States, Egypt, Ukraine, Moldova, Jamaica, Central Asia). He is the lead architect of the energy system models for Kazakhstan, and for the Central Asian Caspian countries, and of their dedicated stakeholder engagement dashboards. He is the author of a number of publications and studies about energy & emissions-related analyses.

Dr. George Giannakidis



Dr. George Giannakidis worked initially as a senior consultant and then as the Head of Energy Systems Analysis Laboratory in the Centre for Renewable Energy Sources and Saving (CRES), Greece for a total of nineteen years. Since 2016 he is working as a freelance Energy Consultant. He has more than twenty years of professional experience in the sectors of renewable energy, energy efficiency, energy planning, energy modelling, energy systems analysis and energy statistics. He has worked in Eastern European countries, in the Middle East, Africa and the Caribbean on energy planning issues, with a focus on the development of energy strategy using energy system models. He is actively involved in the Energy Technology Systems Analysis Project (ETSAP) TCP of the IEA as the Operating agent (2012 - 2016) and Project Head (2017-today).

Eugenia Gusilov



Eugenia Gusilov is the founder of the think tank Romania Energy Center (ROEC). She specializes in energy economics and has worked with NATO, the UN, the World Bank, IFC, Energy Charter, the Romanian Ministry of EU funds, companies, embassies, universities and NGOs on a wide range of policy and commercial projects. Eugenia started out as an analyst for the Romanian Diplomatic Institute, Romanian Ministry of Foreign Affairs, where she covered natural gas developments in Russia, Belarus, and Ukraine (2005-2008). She is a frequent speaker at energy events in Romania as well abroad, with presentations on topics as diverse as Romanian energy policy, Black Sea gas, EU energy law, district heating or energy transition.She holds a MA with a concentration in International Energy Management and Policy from Columbia University in New York (USA, 2010) and a BA in European Studies from Bucharest University (2005). She was a recipient of the Fulbright award (2008). Since 2020 she is a partner of IENE and Member of the Board of Governors.

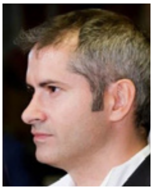
Fadil Ismajli

Fadil Ismajli is an economist and currently serves as CEO of the New Kosovo Energy Corporation monitoring the construction of a 500MW coal fired power plant. He worked with USAID as Executive Director of cross-border transmission project CASA-1000 (1300km AC/DC facility linking Central/South Asia). In 2013-2014, he held the post of Minister of Economic Development of Kosovo. During 2006-2013, he worked as the CEO of KOSTT. In 2005, he led the unbundling of the Kosovo Electricity Corporation (KEK). He helped establish the Kosovo Electricity Transmission, System and Market Operator (KOSTT J.S.C.). In 2003-2005, he worked in private sector and in 2001 he was chairman of KEK. He has participated in in several regional and EU energy bodies. He managed numerous projects in the private sector, both on IT and energy. He has graduated in economics from the University of Prishtina. and attended post-graduate studies in Economic Analyses at the University of Zagreb, while he took numerous professional courses in Croatia, Switzerland, Germany, USA etc. He has published a number of papers in the broad area of energy, economics and IT. He is an IENE partner and member of IENE's Board of Governors

Miki Korner

Miki Korner is mechanical engineer with a B. Sc. from Tel Aviv University. He holds an M.B.A. ¬ from the TAU & Wharton business Schools and he has also a graduate diploma in Regulatory Studies – NAURC, from the University of Michigan. He is an ex-regulator (NAURC), with diverse experience in hi-tec and industries. Between 2004-2009 he was Deputy Manager & Chief economist of the NGA/ Energy Ministry. Since 2010 he has established his own a consulting firm undertaking tech-economics & regulation assignments, supporting entrepreneurs, upstream/midstream gas companies, IPPs', financial institutes, industries, and government. Miki is also teaching at MBA degree courses in Israel and works as an evaluator for technology companies optical devices, AI, machine learning, Industry 4.0 etc.

Alexandros Koutroumbousis



Alexandros Koutroumbousis is a Mechanical Engineer (Meng), a graduate of the National Technical University of Athens (1999) and holds an MSc Degree in Production & Energy Management from the National Technical University of Athens (2003). He also holds a professional practice license from the Technical Chamber of Greece. Since December 2001 he has been appointed to several positions in energy companies (Public Gas Corporation S.A., Ergaz S.A., Attika Gas Supply Company S.A., Natural Gas Hellenic Energy Company S.A.) with responsibilities including commercial policy design, engineering-construction-procurement (ECP) of natural gas installations in Industry/Commercial customers, development and key accounts management, energy markets regulation and policy development/compliance, design and development of sales channels, customer experience teams in retail and wholesale natural gas & electricity markets. He has published in the scientific magazine of the Society of Automotive Engineering (SAE) in the area of computational combustion models application for reciprocating internal combustion engines (2001-2002). He is a contributor to IENE's flagship publication 'South East Europe Energy Outlook' and in IENE's annual report and member of IENE's Scientific Committee for Natural Gas, Biomethane & Hydrogen. He often contributes to IENE projects as a Research Associate. Since November 2020, he has been appointed as the Head for Large & Medium Corporate Customers Sales in Public Power Corporation S.A.

Dimitris Mezartasoglou

Dimitris Mezartasoglou is an energy analyst with more than 7 years of working experience. He is a graduate from the Department of Economics in University of Peloponnese, while he holds two Master's degrees from the University of Strathclyde on Global Energy Management and from the University of Exeter on Money and Banking. He has full exposure across the energy sector, specifically for Greece and SE Europe. His research interests include the economics of European and SEE's energy integration and energy policy making, including gas, renewable energy sources and energy efficiency sectors as well as energy poverty issues. Currently, he works as Energy Economist in Energy Policy Department at the Center for Renewable Energy Resources and Saving (CRES). As part of IENE's Research Team since 2015 he has contributed to various studies and analyses, while he has also overseen the Institute's newsletters.

Mihailo Mihailovic

Mihailo Mihailovic has over 35 years of professional and business experience in the Power Industry of the Republic of Serbia. He possesses extensive knowledge and skills in covering national electricity system dispatching, short and long term operation planning and long term corporate strategic planning. As an evaluator of new energy concepts and technologies, he was involved in the energy strategy development and market projections, along with policy related activities on both national and regional levels. During his career, he was a cross–functional leader in strategic planning, mapping potential and reviewing RES output in the power industry on company, national and regional level. He is a team leader for harmonization and implementation of modern energy statistical methodologies.Contributing editor on energy developments and trends in Serbia and SEE countries for the European annual publications.Mihailo has also authored or co-authored numerous papers and presentations in international conferences and he was a reviewer on many national and regional policy studies regarding energy efficiency, climate-energy changes and regional electricity market development.Mihailo graduated and received his M.Sc. degree in Power Engineering from the Faculty of Electrical Engineering at University of Belgrade. After retiring from his position at the Electric Power Industry (EPS) of Serbia, he has worked as an independent energy consultant and has been appointed as a Partner and member of the IENE's Board of Govenors.

Aleksandar Mijušković

Aleksandar Mijušković, is an electrical engineer and currently serves as the president of the Board of Directors of Montenegrin TSO (CGES Podgorica). Prior to that he worked for the Coordinated Auction Office in South East Europe (2014-2021) and within the period from 2014 to 2019 was the Executive Director. He held the office of the Executive Director of the Project Team Company in charge of establishing SEE CAO from 2012 to 2014. From 1995 to 2009 he was employed with Electric Power Enterprise of Montenegro as an engineer within National Dispatch Centre and from 2009 to 2012 as a director of Department for Regulatory, Legal and International Affairs within Montenegrin TSO. His international involvement include the following positions of Member of: ENTSO-E Market Committee (2009-2012), SETSO Task Force (2003-2009), EURELECTRIC Ad-hoc Working Group (2004-2007), EPCG-TERNA negotiation team on the undersea interconnection between Montenegro and Italy and Montenegrin Delegation: at the European Commission and at Montenegro sub-committee meetings (Brussel 2008, Podgorica 2009) and Participant in Athens Forum since 2003 and Participant in SEE ENERGY DIALOGUE – IENE since 2007 and partner of IENE since 2020.

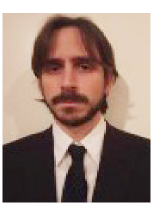
Gus Papamichalopoulos

Gus Papamichalopoulos heads the Energy, Infrastructure and Utilities Practice Group. His main area of expertise is on the energy industry and he has been involved in the liberalization of the Greek electricity market and gas market. Due to the complexity of the issues associated with the electricity market regulations he advises on major regulatory issues of the electricity, natural gas and RES market. As a business lawyer focusing on the energy sector, key international energy companies investing in Greece have mandated. Gus in the early stages of their investment program for the implementation of important energy projects (infrastructure projects such as oil and gas investments, the licensing and development of gas pipelines, the establishment of power generation plants, wind parks, low pressure gas distribution networks, etc). Another element of his practice is the public sector-privatization projects.Project finance is a strong section of his practice, since major local financial and credit institutions and private equity funds are instructing the team for the financing of energy infrastructure projects. Gus also serves as one of the managing partners of KG Law Firm, has acted as co-chair of SEE LEGAL Group for two years. He is a Partner of IENE and Member of the Board of Govenors and currently serves as Deputy Chairman of IENE. Gus Papamichalopoulos is ranked as a leading lawyer in the IFLR1000, Chambers & Partners Europe and Chambers & Partners Global.

Anna Maria Papamichalopoulou

Anna-Maria works for the Energy and Infrastructure practice group of lawyers at Kyriakides-Georgopoulos (KG) Law Firm. Anna-Maria graduated in law from Democritus University of Thrace in 2017 and was awarded an LLM in International Business Law by Queen Mary University of London in 2019, with an LLM Thesis (with distinction) on Green Bonds as a new a financing tool. Her practice focuses on corporate and M&A law in the energy sector and other industries. Anna-Maria also advices international energy companies in the early stages of developing their projects (infrastructure projects such as, oil and gas investments, licensing and development of power generation plants, etc.). She often provides legal advice to corporations in the energy sector with regard to various issues relating to their daily operation, drafting and reviewing various types of contracts and agreements and she is involved in due diligence procedures for mergers and acquisitions both at domestic and cross border level.

Alexandros Perellis

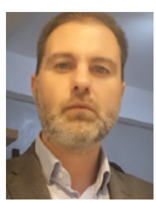


Alexandros Perellis is a graduate of Dpt. of Production Engineering and Management of Democritus University of Thrace's School of Engineering (DUTH) (2010). He also holds a MSc degree in Sustainable Energy Engineering from Technical University of Denmark (DTU) (2013). Currently he is an analyst at Energy Systems Analysis Laboratory of the Center for Renewable Energy Resources and Saving (CRES). Alexandros is a member of Technical Chamber of Greece and has a 5 year working experience in the energy sector, in which he was affiliated with projects regarding developing solar energy systems, modeling and analysis of sustainable energy systems, electricity market analyses and feasibility studies and system assessment of energy technologies. He currently works as an external Research Associate of IENE.. As part of his work at IENE he contributed to various studies and analyses, while he also compiled and edited the Institute's newsletters on regional electricity markets and electric mobility. He worked at IENE as Research Officer from 2017 until 2021.

Mirsad Sabanovic

Mirsad Sabanovic is currently the director of ASA Energija, a company that is a supplier of electricity and is engaged in the development of larger RES generation facilities in BiH. He is also engaged in regional projects related to the electricity market and market coupling projects. Mirsad Sabanovic was Executive Director for Supply and Trade of electricity and Member of Management Board (2011-2015) at the biggest power utility in BiH. During his professional career, he worked in several positions (Manager of Market Operation department in the Independent System Operator of BiH, manager of electricity wholesale department, dispatcher at the national control center).Mirsad has more than 25 years of experience in the electric power sector. He is the author and co-author of several professional papers and studies on electricity markets and the economics of electric power systems. He was a member of SETSO TF (SEE Transmission System Operator Task Force) and a few SETSO subgroups and ENTSO-E Market Committee and their SEE Regional Group. President of Study Committee C5 - Electricity Market of BH K CIGRE and since 2020 he is a partner and Member of the Board of Governors of the Institute of Energy for South East Europe (IENE).

Nickolas Sofianos



Nickolas Sofianos, holds an Mphil in Development Studies from the University of Glasgow in Scotland (2005). He is an independent energy consultant while he is a Partner and member of IENE's Board of Governors, and chairman of IENE's RES Committee. Over the years Mr. Sofianos has published several studies, reports and specialized papers on energy, economy and policy issues and contributed articles on energy, geopolitics and related subjects. He has authored, co-authored and edited several Studies and Research Papers. Through his research, he succeeded high level of expertise in collecting and analyzing energy and macroeconomic indicators and other statistical data. He worked initially as research coordinator and then as a Senior Research Associate at the IENE from 2008 until 2017. He has served as Energy Consultant and Development Economist expert, providing advisory services to large institutional clients (ministries, regulatory authorities, associations) and companies in the energy policy, oil, gas, electricity and RES sectors, while he participated in several working groups with the main goal to promote climate change policies, decarbonization processes and clean coal technologies. As an energy expert, he specializes in relations between governments and companies with a focus on energy, environmental, and public sensitive issues. Over the years Nicholas co-operated with various public and private institutions and organizations in the whole SE European region (ministries, organizations, regulator authorities, NGO's, associations, companies etc.) acting several times as a bridge between companies and governments in SE Europe in order to facilitate interaction between them and market openness. He also deals with the investment part of energy as he participates in several photovoltaic projects but also in the field of biogas.

Costis Stambolis

Costis Stambolis is the Executive Director of IENE and currently serves as IENE's elected chairman. Costis has a background in Physics and Architecture having studied at the University of London, the North East London Polytechnic (NELP) and the Architectural Association in London from where he holds a Graduate Diploma in Architecture and Energy Studies (AA Dip. Grad). He also holds a professional practice license from the Technical Chamber of Greece (TEE), and a Masters Degree from the Said Business School, University of Oxford, where he studied "Strategy and Innovation". He has worked as a consultant and strategy advisor on natural gas, oil markets and energy security issues for large multinational companies, international organizations and governments. He has lectured widely on energy issues and has organised several national, regional and international conferences, seminars and workshops. He has published several books, conference proceedings, research papers and studies on energy policy, solar energy. Since 2001 he supervises and edits daily Greece's foremost energy site www.energia.gr. He is a founding member of the Institute of Energy for South East Europe (IENE), which he currently chairs. He is a member of the Energy Institute (UK), the International Passive House Association (IPHA), The Technical Chamber of Greece (TEE). Since 2018 he is a full member of the Greek government's standing committee on Energy and Climate Change (NECP).

Kaloyan Staykov

Kaloyan Staykov has been the Chief Economist at the Energy Management Institute since July 2021. Prior to that, for ten years, he has worked as an economist at the Institute for Market Economics in Sofia, where he dealt with analyses in the field of public finance, energy, business environment, healthcare, and other. Prior to joining the IME team, he worked as an economist at the Center for Economic Development. He is part of a group of experts and economists who have been pushing for years to increase competition in the energy sector until its full liberalization. He is the author of a number of publications and analyses in this direction, including: "Integration of electricity producers with long-term contracts on the market" and "Regulatory policy in the electricity sector in 2013 - contrary to regulations and common sense."He is a member and deputy chairman of the Bulgarian Macroeconomic Association. PhD candidate at the Faculty of Economics, Sofia University "St. Kliment Ohridski". He holds a Master's degree in Economics and Management in Energy, Infrastructure and Utilities from Sofia University "St. Kliment Ohridski", and a Bachelor's degree in International Economics and Business with a specialization in Finance from the University of Amsterdam, the Netherlands.

Terzidou Eirini

Terzidou Eirini joined IENE in 2021. She is a graduate from the department of Chemical Engineering of Aristotle University of Thessaloniki and holds an MSc degree in Environmental Technology from the University of Manchester Institute of Science and Technology (UMIST) and a Master of Business Administration (MBA) from the European University of Cyprus. Eirini has strong background related to the environment and energy sector. In 2013, she was hired by the Centre for Renewable Energy Sources (CRES) to be involved in the licensing process of renewable energy sources (RES) projects (issuing production/installation/operation license) for the Department of Renewable energy sources at the Ministry of Environment, Energy and Climate Change. She was also responsible for providing information to investors on the institutional, legislative, fiscal and financing framework necessary for the licensing procedures for investments in RES. In addition, she has worked in the area of management systems, especially in designing and implementing quality and environmental management systems (ISO 9001/ISO 14001) in different kind of companies. Eirini has also conducted sectorial studies in the field of renewable energy sources, waste management and recycling. She currently works at IENE as Research Fellow in charge of ESG, Green Bonds, energy & employment and related issues

Costas Theofylaktos

Costas Theofylaktos is a USA trained Mechanical Engineer with an MSc from the University of Evansville, Indiana, and has 30 years experience in the energy sector. Costas's special interests include energy efficiency, cogeneration and RES. He was for many years chairman of Hellenic Association for CHP and also member of the executive committee of COGEN Europe. He has served as chairman and CEO of the Athens based Centre of Renewable Energy Sources and Saving (CRES). He has participated as invited speaker in several conferences and seminars, and he has considerable experience in lecturing on energy efficiency techniques. He has worked globally as a senior consultant for several organisations including the EU, World Bank, EBRD, the Energy Community ao,. He is a Partner and Member of the Board of Governors of IENE where he is Secretary General of the Institute and also chairs the Energy Efficiency Committee.

Dr. Halil Yurdakul Yigitgüden

Dr. Halil Yurdakul Yigitgüden is an independent consultant specialising on energy economics and he is also a non-executive Board Member of CHS. From 2013-2017 he served as the Co-ordinator of OSCE Economic and Environmental Activities in Vienna. Between 2004-2012 he advised several international companies on investment climate and geopolitics in the region and was Board Member of BorusanMannesman (2007-2013), BorusanEnBW Energy (2008-2012) in Istanbul and Senior Policy Expert of the EU MED-ENEC project promoting solar energy and energy efficiency in ten Mediterranean countries (2006-2008). From 1997-2003 he served as Undersecretary of the Turkish Ministry of Energy and Natural Resources. He took a leadership role in the Caspian region energy diplomacy and in implementing energy market reforms in Turkey. From 1995-1997 he held the position of CEO of Fenis Holding in Istanbul. Prior to that he served as chairman and director general of the State Airports and Air Traffic Authority (1992-94); as deputy under-secretary of the Ministry of Transport and Communications (1991-92); as vice-president of the mining chemicals and banking Group Etibank (1989-91) and as group manager for Investment Promotion at the State Planning Organization (1987-89).

Peer Reviewers

A small number of academics, senior experts and company executives between them undertook the peer review of the report. Some of them read whole chapters and offered specific comments, corrections and advised on new input. Others contributed valuable advice on the structuring of individual chapters and the report as a whole. Their ideas, suggestions and critique proved of great value and vastly contributed to the improvement of the final Outlook report. We are indeed most grateful to all of them. They include the following:

Dr. Costas Balaras

Costas Balaras is a Mechanical Engineer with a degree from the Michigan Technological University (B.S.M.E) and has a PhD from the Georgia Institute of Technology. He is the leader of the Group Energy Conservation in IERSD at the National Observatory of Athens (NOA). He has been project coordinator, scientist-in-charge and participant in over 35 R&D and demonstration projects financed by the European Commission, national Ministries and organizations, and the private sector. His teaching covers renewable energy sources, rational use of energy, heat transfer, thermodynamics, fluid dynamics. Research Interests and accomplishments include: Research and development in the areas of renewable energy sources, energy conservation, thermal and solar building applications, building energy audits and building retrofitting, indoor environment, numerical modelling of thermal energy systems and building thermal simulations, HVAC installations, solar cooling, solar radiation and meteorological measurements and computer tool development.

John Chadjivassiliadis

He is Mechanical and Electrical Engineer of the NTUA (1960) and expert in the development of the renewable energy sources and sustainable power systems. He worked for the Public Power Corporation (1962-1990) in the department of power generation, where he was director of power plants, and project manager in large power plants. From the mid-1970s John was in charge of the development of wind and solar energy projects for power generation with the successful Windpark of Kythnos, the first in Europe (1982) and the biggest hybrid by wind and solar PV. Since 1990, he is a consultant engineer in energy, especially in the renewable energy sources, energy efficiency and sustainable development. For many years he served as an expert in evaluating research proposals and programs, coordinator and technical assistant of large research projects for RES integration into the networks within the European Commission research programs. John has been a scientific committee member in a number of European and international conferences, invited lecturer in international events and conferences where he presented over 80 papers. He is a founding Member of the European Wind Energy Association (EWEA, 1982), member of national and EU missions for international cooperation in scientific research and technology, founding Member and Secretary General of IENE, National Representative in the Mirror Group of the European PV Technology Platform, and Member of the Scientific Committee of the Hellenic Association of Mechanical and Electrical Engineers. John is the recipient of the "Prize Aeolus" Award, for his contribution in wind energy development by the Hellenic Wind Energy Association-member of EWEA (2009), as well as of the "2010 PES Chapter Outstanding Engineer" Award, for his contribution in renewable energy research and development by the IEEE Power & Energy Society, PES Greece Chapter. John was IENE's Chairman (2013-2019).

Dr. Spyros Chatzivasileiadis

Spyros Chatzivasileiadis is an Associate Professor at the Technical University of Denmark (DTU) and the Acting Group Leader of the Energy Analytics and Markets Group at the Center for Electric Power and Energy at DTU. He is a graduate in Electrical and Computer Engineering from the National Technical University of Athens (NTUA), Greece (2007) and he holds a PhD from ETH Zurich, Switzerland (2014).

Dr. Stavri Dhima

Stavri Dhima is an independent energy consultant based in Tirana, Albania. Until recently he was the Head of Primary Policies Sector and of the Unit, Regulatory and Managing Sector for Petroleum Projects, Contracts and the General Regulatory Directorate, at the Ministry of Economy, Trade and Energy in Albania. During 1979-1998 he worked at the Geophysical Enterprise and at the Oil and Gas Institute in Fieri, where he was the Director (1997-1998). He has a degree in Physics from the University of Tirana and a PhD in Geophysics (1997). Since 2001 he is an Associate Professor of Geophysics at Tirana University. Dr. Dima has contributed in the preparation of the legal and institutional framework for the Albanian oil and gas sector. He was the head of the inter-ministerial working group for the Law, responsible for security of gas supply. He is member of several professional and scientific associations. He has participated in numerus international conferences and meetings, where he has presented scientific papers and analysis. Dr. Dhima has also contributed various scientific monographs on the Albanian petroleum and energy sector and he has been the head of several working groups, for Energy and particularly for the Petroleum Sector in Albania. Stavri Dhima is a Partner of IENE and a Member of the Board of Governors.

Christodoulos (Christos) Dimas

Christos Dimas is a Land Surveyor and a Civil Engineer, having graduated from the National Technical University of Athens (1974). He has managed major projects on Energy, Industry & Infrastructure (Europe, Saudi Arabia, Russia). He was a senior executive and board member in various businesses and organizations (Petrola Hellas, Petrola International, Hellenic Petroleum, Helpe - Thraki, Trans Balkan, Construction companies, etc.) Christos Dimas represented the Greek Ministry of Development in international energy issues and participated in international conferences with presentations on the transport of oil and gas from Russia, Central Asia and the Caspian Sea to the international markets. He has held a number of executive positions including General Director of TBP B.V. (Burgas -Alexandroupolis Oil Pipeline) and Chief Executive Officer of TBP B.V. – Greece and General Manager of Helpe-Thraki SA. He was the President of the Hellenic-Russian Chamber of Commerce (2011-2017).He is a Founding Member and Partner of IENE, where he currently chairs the Geopolitics & Energy Committee.

Prof. Antonis Foskolos

Antonis Foskolos is an emeritus professor at the Technical University of Crete and an emeritus Researcher at the Geological Survey of Canada. He has worked for a number of years in the Institute of Sedimentary and Petroleum Geology of Canada and has taught at the School of Mineral Resources and Engineering at the University of Crete. He has published extensively in international journals and he has authored several special reposts for the Greek government and the UN.

Liana Gouta

Liana Gouta is the Director of Energy Policy & International Affairs at the HELLENIC PETROLEUM Group of Companies (HELPE). She holds a degree in Chemical Engineering, MSc, with Honors. She started her career as a process engineer in the Thessaloniki Industrial Complex of HELPE and she has many years of experience in several managerial positions, such as Energy Policy, Change Management, Operations and Process Design, Product Development, Environmental Management & Industrial Safety. She has also worked as Parliamentary Advisor to the European Parliament, on Industry, Energy and Environment. She is a member of the Board of Directors of the European e-Fuel Alliance, an alternate Board member of the European Petroleum Refiners Association and a Board member of HELPE Kyparissiakos Gulf SA. She is also Chairwoman of the Downstream Committee at the IENE-Institute of Energy for South - East Europe. She is active in associations and socially engaged in environmental issues, entrepreneurship, leadership and women's empowerment for many years.

Ivan Ichenko

Ivan is a petroleum geologist with more than 40 years of field experience. Among others he served for a number of years (1994-2000) as head of SE Europe and Mediterranean operations at 'Enterprise' (since acquired by Shell) and has considerable experience and knowledge of the geology of the Balkans and SE Europe. Until recently he was the head of Operations at Gazprom UK Resources, and an Executive Director and General Manager of Spike Exploration UK, an Upstream Oil and Gas Advisor.

Dr. John Kampouris

Dr. John Kampouris is an Electrical Engineer with Ph.D from the Technical University of Athens. He served for a number of years as General Director of Operations, Infrastructure and Development at the Independent Electricity Transmission Operator (IPTO) of Greece. Since May 2020 he is the CEO and Chairman of the Southeast Electricity Network Coordinator Center (SEleNeCC) which is headquartered in Thessaloniki.

Prof. Andrey Konoplyanik

Dr. Andrey A. Konoplyanik is an energy economist by background. His major professional areas include: energy economics, energy & investment legislation, energy financing. PhD (1978) & Dr. of Science (1995) in international energy economics, Professor in International Oil & Gas Business (2012). He is currently an Adviser to the Director General, Gazprom export LLC (since 2013) and Co-chair from Russian side of Work Stream 2 "Internal Markets", Russia-EU Gas Advisory Council (since 2011). He is Professor at the Chair "International Oil & Gas Business", Russian State Gubkin Oil & Gas University (since 2008). He is also an Honorary Fellow, Center for Energy, Petroleum and Mineral Law & Policy, University of Dundee, Scotland, UK (since 1994); Associate Member of the Institute of Energy for SE Europe (IENE), Athens, Greece (since 2015) and of the Center for Energy Law, University of Aberdeen, Scotland, UK (since 2018). Detailed professional biography of Prof. Dr. A.Konoplyanik, his publications, presentations and interviews are presented at www.konoplyanik.ru.

Konstantin Konstantinov

Konstantin Konstantinov is the CEO of the Independent Bulgarian Energy Exchange EAD (IBEX) since its establishment in 2014. He has a Master's degree in "Electrical engineering" from the Technical University of Sofia. He also holds a Master's degree in "International Business Relations" from the same university. Konstantinov has got a solid experience in energy sector. Prior to this role, he was an Electricity trade director at the Bulgarian electricity public provider - National electricity company EAD (NEK) and a member of the board of directors of NECO S.A.

Prof. Dimitrios Mavrakis

Professor Dimitrios Mavrakis is the Director of the Center for Energy Policy and Development (KEPA) at the National and Kapodistrian University of Athens. He is also coordinator of PROMITHEASnet, the Energy and Climate Change Policy Network, consisted of academic institutes from S.E. Europe, Black Sea and Central Asia. Furthermore, he is the coordinator of the "BSEC – Green Energy Network" focused on RES and Energy Efficiency for scientists, market stakeholders, and policy makers, mainly from the countries of BSEC.

Slavtcho Neykov

Slavtcho Neykov has more than 25 years non-interrupted experience in the energy sector, including as Secretary General of the Bulgarian Ministry of Energy, Commissioner in the State Energy Regulatory Commission, expert at the Energy Charter Secretariat in Brussels and a Director of the Energy Community Secretariat in Vienna. Prior to his involvement in the energy sector, he has worked as a state prosecutor and a legal advisor. In addition to a law degree from Sofia

University, Mr. Neykov has completed two years postgraduate studies on International Economic Relations and Foreign Economic Activities. He also holds a Master of Arts degree in European Integration from the University of Limerick in Ireland. Since the end of 2014, he is the Chairman of the Board of Managers of the Energy Management Institute (EMI). He is a partner of IENE and member of the Board of Governors.

Apostolos Petropoulos

Apostolos Petropoulos holds a Bachelor and Master degree in Electrical and Computer Engineering from the National Technical University of Athens. He has 8 years of experience in the energy sector participating in a number of European and country specific projects, with the main aim to assess policies and their impact on energy demand. As a previous member of the PRIMES Modelling Team, he was involved in numerous European Commission projects related to the transport sector and the biofuels market, using PRIMES-TREMOVE and PRIMES-Biomass models. He works at the World Energy Outlook of the IEA in Paris team preparing medium and long-term energy outlooks with particular emphasis on end use sectors since 2017. He leads the transport analysis with a particular focus on electro-mobility, demand response and battery demand.

Prof. Ionut Purica

Professor Ionut Purica is a senior researcher at the Romanian Academy's Institute for Economic Forecasting, and Executive Director of the Advisory Center for Energy and Environment, Dr.Purica was also a counselor of the Minister of Economy and previously the Minister of the Environment and an expert for the Parliament of Romania. He participated in the elaboration of the EU accession strategy for Romania and the energy (electricity and heat) strategy (for the Ministry of Economy and Trade) and enrolled on the risk analysis and transaction structuring and project management with the World Bank, USEA, JBIC, MARSH, ITOCHU, MVV, etc. Prof. Purica has authored books in his field of expertise e.g.(Imperial College Press, Academic Press, etc.) and published articles in journals like Risk Analysis, IEEE Power Engineering Review, Foundations of Control Engineering, Romanian Journal of Economic Forecasting, etc. He took his second PhD in economics, (the first one in Nuclear Energy Engineering) and, he is also Professor, teaching a course in Project Risk management to masters of science programs.

Nenad Stefanović

Nenad Stefanović is an Electrical Engineer and a senior expert for electricity at the Energy Agency of the Republic of Serbia (AERS). Since 2016 he is the President of the Study Commitiee of Electricity Markets and Regulation within the Serbian Committee of the International Council on Large Electric Systems (CIGRÉ). He is a regular contributor to international conferences and symposiums and the author of numerous papers. He has worked closely with IENE as a Research Associate on a number of projects.

Theodore Terzopoulos

Theodore Terzopoulos is a Chemical Engineer MSc (Politecnico di Milano), and also a Gas Engineer CEng (Institute of Gas Engineers, UK). He joined the Greek gas industry in 1989 and since then he has been continuously employed in all activities related to the gas distribution sector (construction, operation, maintenance of networks, billing, client's acquisition, management) as Director, Chief Director and General Manager. He has followed closely the introduction of natural gas to Greece and has contributed actively to the development of its gas grid. He was appointed CEO in two Gas Distribution Companies, namely EDA SA (2010-20212) and DEDA SA (2017-2018). Today he holds the position of Coordinating Director on Strategy & Corporate Affairs in DEDA SA. He holds severe professional affiliations including the Institution of Gas Engineers (Member), the Engineering Council (Charted Engineer), Eurogas Distribution Committee (Member), and GEODE, The Federation of European Distribution System Operators. Since 2020 he serves as Chairman of IENE's Natural Gas Committee.

Gokhan Yardim

Gokhan Yardim is a chemical engineer and currently he manages his own consulting firm ADG, Anadolu Natural Gas Trade and Consultancy Ltd. (www.adgltd.com.tr). In 1979, he started working as an operation engineer in the Maltepe Town Gas Factory of the Electricity, Gas and Autobus Authority of Ankara (EGO), where he was awarded an OECD grant in 1982 for onsite training on natural in British Gas Corporation in Britain. Since 1983 he has worked as an engineer in the General Directorate of BOTAS. (http://www.botas.gov.tr/) where he became a chief engineer, director, coordinator, department chief, General Manager and Chairman of the Board in Botas from 1983 to 2001. During his employment with BOTAS, he took part in various natural gas related projects, starting from preliminary studies for importing natural gas. In addition to natural gas purchases, he was also involved in the marketing and sale of natural gas and took part in the drafting and signing of intergovernmental and main contractor agreements regarding the BTC (Baku, Tbilisi, Ceyhan) Crude Oil Pipeline. In 2011, he was appointed as the general manager of Angoragaz Gaz Ticaret Sirketi. Angoragaz is a wholesale company holding a spot LNG import license, and has been operating as a key player in the Turkish natural gas market. It purchases natural gas from other wholesale companies and importers and sells it to distribution companies and industrial companies. For the past 3 years, Gokhan Yardim has been elected as Board Member of PETFORM (the Petroleum Platform Association) and since 2008, he has been an Associate of IENE having participated in several conferences and workshops for the Institute.

Milan Zdravkovic

Milan Zdravkovic is the assistant CEO for Economy at JP Srbijagas. He is a Mechanical Engineer with an MSc from the Dpt. of Aeronautics at the University of Belgrade, Serbia. Currently he is in charge of strategic development activities in the gasification programme of Serbia. He has also active cooperation with the international institutions including IGU, UNECE, DVGW, IENE, ECS, EC DG Energy, EC CESEC. He has acted as project leader in several JP SRBIJAGAS strategic projects including the Gas Interconnector Serbia – Bulgaria (Serbian part)

Executive Summary

One of the main challenges which IENE faced when it decided to embark, once again, upon this major regional project was the definition of the geographical area under examination. This became even more challenging as the contributors of the 2011 and 2017 studies (i.e. the first and second SEE Energy Outlook study which IENE published) as well as the current ones did not merely come from an interdisciplinary scientific background but also represented several states in the region, such as Albania, Bulgaria, Croatia, Cyprus, Serbia and Turkey to mention just few of them. Admittedly it is difficult, if not risky, to define SE Europe as a separate energy system as it is equally hard to think of it as a unified political sub-system of modern European geopolitics.

The finally-defined region is too diverse politically, culturally and economically in order to be "separated" from other far more culturally cohesive and politically distinct regions, such as the Middle East and the Former Soviet Union, geographical areas which also happen to contain states which are major oil and gas producers and hence energy exporters to SE Europe, and as such present both potential energy risks but also offer opportunities. Yet, this perennial diversity and complexity are some of the most common characteristics of the SEE region.

A region, which has been moving slowly, but steadily over the last 20 years or so towards a new path of economic prosperity, political democratization and geostrategic stability – if not yet – reconciliation, within a common European and Euro-Atlantic future.

The historical and political framework of the SEE region is detailed in **Chapter 1**, along with the role that energy can play in creating and deepening the economic synergies, which are necessary in order to keep the region both in peace and en route to a better and more integrated European future. In this context, the importance of the "Energy Community" is stressed together with the latest policy initiatives of the EU, such as the "Energy Union" and the new "Fit for 55" package. West Balkans is recognized as an area of special significance within the broader SEE region. However, the level of market liberalization and integration both within the area and between the

Map 1 **The SE European Area Defined***

*This comprise the 15-country group being examined in this Outlook study.
Source: IENE

[2] IEA (2018), "Energy in the Western Balkans – The Path to Reform and Reconstruction", https://iea.blob.core.windows.net/assets/6f3556ba-55bc-4d5b-927c-2d027fd2ebfb/Balkans2008.pdf

region defined by the EU Member States that surround it remains incomplete to the detriment of the region's economic/energy rehabilitation and the pace of its prospective inclusion into Euro-Atlantic institutions, and notably the European Union. This emerges as a major challenge and simultaneous impediment for the prospective inclusion of West Balkan states into the European Union as this is not merely an issue of economic under performance. As we explain in **Chapter 1** the historical background and the political content still matters a great deal.

Although the economies of the SEE region appear widely divergent in terms of structure and level of development, they share a number of challenges, which appear to be common to all. Among these, the global economic and financial crisis as well as the impact of the coronavirus pandemic have deeply affected the region collectively and each country individually. **Chapter 2** highlights the economic development challenges of the region and also examines the key economic problems facing the various countries. The present "Outlook" takes the view that, in the post-crisis period in terms of economic and financial prosperity and COVID-19 implications, only states whose governments possess the political determination to cease managing the economy through outdated state control mechanisms will eventually thrive. This is especially relevant to the energy sector which forms a key part of the economies of most countries in SE Europe and which, as it is clearly demonstrated in the present study, is in the process of rapid transition towards decarbonisation.

Today, energy policy formulation and decision making in the SE European region is facing tremendous challenges for a number of reasons (see **Chapter 3**), but primarily related to geography and security considerations, to the existence of abundant but largely unexplored indigenous energy resources, to the divergent demographics, to the great inequalities present in the economies of the various countries and last but not least because of the demands, made by the EU, both to member countries and Energy Community Contracting Parties, for decarbonisation commitments.

In the group of 15 countries examined in the current "Outlook", seven are full members of the European Union and hence bound by means of current treaties and EU Directives to well-defined energy and environment related policies and specific targets, six countries in the Western Balkans are Contracting Parties of the Energy Community and have hence embarked on the road of fully adapting their energy legislation to the Energy Acquis, and finally Turkey and Israel, which have already achieved significant progress in adapting their legislation and market operation to EU requirements, in line with their Association Agreement with the EU.

Looking at the broad map of SE Europe, it is useful to examine the big picture and get acquainted with the key issues which confront the region's energy sector (see **Chapter 4**). These include the **glacial change of the regional energy mix** between 2000 and 2019, as shown in Figures 1 and 2, which in spite of the huge rise of renewables and large contribution of gas remains bound to high solid fuel consumption and sizable oil imports. In addition, there is less use of solid fuels, but the retreat is not as big as anticipated so as to advance EU's decarbonisation agenda. Therefore, there is a major policy challenge, which the governments of the countries concerned and the EC, sooner rather than later, will have to address.

Chapter 5, which is the largest one of the study, not only explains how the aforementioned key energy issues translate into policy imperatives at national level, but also offers a scholastically detailed presentation of the energy system and energy resources of each of the 15 SEE countries. The Chapter contains "Energy Profiles" for each country where a concise presentation of each country's basic political and economic data as well as the basic policymaking mechanisms in the energy sector are included. Each country's "Energy Profile" also analyzes the basic trends of the country's energy supply and demand. Following that, the country's energy policy is presented on a sector-by-sector basis starting with oil, natural gas, solid fuels, electricity, renewables, energy efficiency and combined heat and power. The Country Energy Profiles also include comprehensive data on energy imports and exports and on basic energy infrastructure.

There is also a group of countries, which are termed as peripheral countries, with which the SEE region maintains close economic and trade relations including energy.

These countries (i.e. Azerbaijan, Austria, Moldova, Ukraine, Italy, Slovakia, Syria, Lebanon and Egypt), presented in **Chapter 6**, are important to the present "Outlook" study as they are associated, in terms of direct energy flows but also trade links, with the region. Each of these countries, for different reasons each, is important as they influence energy related developments and issues in the various countries of the region.

The legal framework for the operation of the energy markets in all countries of SE Europe is described in detail in **Chapter 7**, which also contains ample references to latest legislation per energy source. This is an exhaustive Chapter in the sense that the energy legal background is presented in the same detail for all countries (Bosnia and Herzegovina, Hungary, Israel excluded).

Apart from presenting the current energy situation in SE Europe on a country-by-country basis, there is an analysis per energy source for the entire region. **Chapter 8** provides a comprehensive review of the hydrocarbon exploration and production in SE Europe, as both have been undoubtedly affected due to the coronavirus pandemic.

Chapter 9 covers the oil and gas sector, including oil and gas midstream and downstream (i.e. transportation, storage, refining and retail market activities in the various countries) as well as a separate subsector with a specific reference to gas market, focusing on latest gas market developments and gas demand and supply situation in SE Europe, among others.

Special reference is also made to LNG because of its growing importance for the secure operation of various countries' gas networks and because of its potentially crucial role in market development and competition. In this context, all ongoing or planned gas interconnection projects are examined together with the major cross-country gas pipelines currently under construction or in a development phase. In view of several new projects under development in the region, a redefinition of the Southern Gas Corridor is presented in this Chapter by mapping all new potential gas supply sources and routes.

Therefore, the concept of an **Expanded South Corridor** is introduced and defined as such, to include all major gas trunk pipelines, LNG regasification terminals and underground gas storage facilities, which will ensure that gas if fed into the system with some of them being re-directed towards the main European gas markets.

Finally, this Expanded South Corridor, with its multiple gas entry points and linked underground gas storage and LNG facilities, will provide the necessary background for the operation of regional gas trading hub(s). As a matter of fact, a discussion is made on the possibility of establishing such regional gas trading hubs very much in line with similar gas hubs currently operating in various European countries.

Currently, the electricity sector in SE Europe, as analysed in **Chapter 10**, faces several significant challenges that mainly derive from the ongoing process of market transformation but also the current economic climate, which is the basic driver behind demand. The industry structure, in terms of ownership and regulation framework, being under consideration for a long time, is currently changing in many countries facilitating market competition. The role of the state is reconsidered and the level of privatization and liberalization of electricity markets shapes the business environment in each country, creating new opportunities for market players, especially in the power generation and retail sector.

The presence of new market entities (both old and newly established), like power producers, transmission/distribution system operators and retail suppliers, in each country illustrates the magnitude of changes that the gradual introduction of competition has brought about.

In this context, the main challenges include: **(a)** reform efforts for improving the power market model in line with EU Directives, **(b)** the continuing dominance in many countries' electricity markets of the present incumbent, **(c)** vulnerability to supply disruptions, **(d)** lack of diversification of power generation sources and **(e)** the observed low rate of switching supplier, which involves only eligible consumers who can exercise their right to switch supplier (mainly because of inertia as well as customers' poor awareness and mistrust of new incomers). Factors that have led, in many cases, to a power sector unable to be financially self-sustained, because of the high level of distribution losses, poor collection practices, high rates of illegal electricity usage and tariffs that do not reflect the cost structure.

Ever since the start of the process for developing the internal market in electricity by the European Community and then the EU, the energy sector and more particularly the electricity sector has monopolized EC's attention. It has taken more than 25 years of persistent efforts and countless disagreements and legal cases with incumbent electricity authorities for the European Commission to manage the transition from a state-controlled electricity sector to an open and market-oriented system where competition between different producers, suppliers and distributors forms the basis of operation. In SE Europe, this liberalization process was frought with difficulties and numerous non-technical obstacles, as the incumbent companies in almost all countries solidly resisted any change on the grounds of losing control of the market and hence weakening of their bureaucratic hold.

The situation between EU Member States and Turkey and Israel looks very different with certain countries having managed to complete what appeared to be an anomalous transition period. For instance, in the case of Turkey, the achieved progress in the unbundling of electricity market operation and competition in the retail area has been exceptional and it has now entered into a critical stage with the market opening up much faster than anticipated.

In the case of the Western Balkans, the intervention of the Energy Community through the Contracting Parties has facilitated, on several occasions, the overall transition process to the European Acquis. Hence, some solid steps have been made towards electricity market competition.

Moreover, SE Europe as a whole presents a huge potential for the exploitation of Renewable Energy Sources (RES). Today, although RES penetration is limited in SE Europe, the potential for the utilization of all different forms of RES in the region is quite considerable, as it is clearly described in **Chapter 11**, which covers all different aspects of RES applications, including solar thermal, solar photovoltaic, wind, hydroelectric (both large hydro and small hydro stations), biomass and geothermal. Some countries, such as Greece, Turkey and Cyprus, are very advanced by international standards in solar water heating with millions of installations in place, but less so in electricity generation from solar energy. Indeed photovoltaics are slowly but steadily making their entry into local markets with Greece, Bulgaria, Romania and Turkey in the forefront.

Wind applications are also on the rise with Greece, Turkey, Romania and Bulgaria showing most activity. Hydroelectricity is a common denominator in RES development with almost all countries showing strong interest, especially those that are already using hydro to cover a substantial part of their electricity needs (i.e. Albania, and the rest of the Western Balkan countries, but also Greece and Turkey).

Energy efficiency and relevant application areas in SE Europe are discussed in **Chapter 12**, analyzing the energy efficiency trends of the near past in industrial, household and transport sectors. Cogeneration of Heat and Power (CHP) in SE Europe, which is also analysed in Chapter 12, can be described by its diversity. There are countries, such as Romania, Bulgaria and Slovenia, where CHP plays a serious role in their energy policy during the past period under planned economic models but also today, and there are countries, such as Cyprus, where the role of CHP in their energy mix is insignificant or minimal.

One innovation of the present "SEE Energy Outlook" study is the incorporation of a separate Chapter concerning energy technologies perspectives in the wider region. Energy technology is an engineering science whose main purpose is the efficient, safe, environmentally friendly and economically viable extraction, conversion, transportation, storage and use of energy, preventing at the same time side effects on humans, nature and the environment. After the Second World War, huge progress has been achieved in developing the energy technologies used globally, while continuous technological progress has resulted in numerous improvements and higher efficiencies as well as the introduction of new low-carbon technologies.

The aim of **Chapter 13** is to review the main energy technologies already in use in SE Europe, but also identify others suitable for application in the region. Technologies, such as more efficient batteries for the faster deployment in electric vehicles' as well as the introduction of hydrogen, biomethane and CCUS are only some of them.

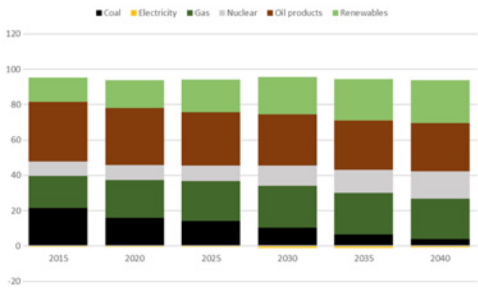
Furthermore, a clearer view of the region's energy profile can be derived by forecasting energy demand and supply over the next 20 years, within the constraints of stated assumptions (see **Chapter 14**). This in turn helps considerably the formulation of desired policies not just on energy but also over a broader spectrum involving vital economic and social issues.

The most recently available studies and the official country submissions of strategic documents (such as the Integrated National Energy and Climate Plans for the EU Member States of SE Europe) were used in order to collect and analyse these projections. The purpose is to present the evolution of the national energy systems corresponding to a "where we are heading" storyline, providing a simple but comprehensive picture of the energy and greenhouse gas (GHG) emissions dynamics under the "current policy" efforts until 2040.

In order to study energy demand and supply patterns, a scenario approach was adopted and presented in **Chapter 15**, whereby certain assumptions have been formulated concerning basic parameters, which are likely to govern future energy demand and supply. These parameters include primarily economic, demographic and energy price information. In the present "Outlook" study, only one such scenario was selected for elaboration, namely the "Baseline" scenario. Looking at the projection of the gross inland consumption in the EU member states of the SEE region in Figure 3, the overall tendency shows a stabilisation and even a small reduction in the time horizon to 2040.

The decrease of the use of coal is evident, reaching a minimum level by 2040, while oil products lose part of their share in the gross inland consumption. The winners to this change are RES and nuclear energy.

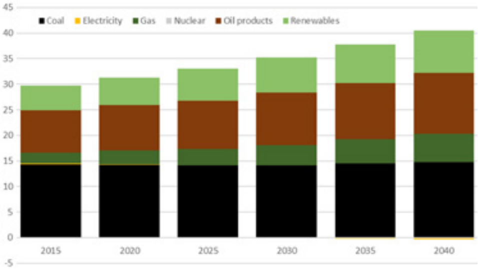
Figure 3 **Gross Inland Consumption in SEE EU Member States, 2015-2040**



Source: IENE

Similarly, the projection of gross inland consumption in the six Western Balkan countries in Figure 4 presents a rather different story from that of the EU member states in the region. Following the expected growth of GDP, gross inland consumption is projected to increase by almost 40% between 2015 and 2040, with the amount of coal being held almost constant, close to 15 Mtoe. Natural gas is the emerging fuel with a constant gradual increase, connected with the pipeline and grid expansion projects in the East and Western Balkans region. Crude oil and oil products will increase by 45% reaching 12 Mtoe in 2040, and renewable energy will rise substantially (by 70%) to 8.3 Mtoe in 2040, but still covering only 20% of the total gross inland consumption of the group of countries.

Figure 4 **Gross Inland Consumption in the Six Western Balkan Countries, 2015-2040**



Source: IENE

The investment and business potential of the region is analysed and discussed in the final section of the study, in **Chapter 15**. A detailed analysis has been undertaken in two directions **(a)** country-related investments and **(b)** cross-border energy project related investments. Country investments are reported using a standardized information format with primary information derived directly from sources in each country, while cross-border project information has been compiled using both published and company sources.

Investment prospects in the broader SEE region for energy related basic infrastructure and energy projects across the board (i.e. electricity, natural gas, RES, thermal power plants, oil and gas exploration, energy efficiency) look positive over the next decade. There appears to be significant improvement in anticipated and planned projects and related investment from now on until 2030. Compared to projections made in 2017 for the period 2016-2025, total estimated energy related investment in the region is much higher and amounts to €483.7 billion. Corresponding investments for the original 13-country group (as they appear in the 2017 Outlook) are slated at €387 billion, which is 41.8% higher compared to the 2017 estimates. This is a vast improvement compared to 5 years ago and clearly shows the substantially increased interest and appetite for energy investments in SE Europe.

Another innovation of the present "Outlook" is the special focus on issues of Environmental, Social and Corporate Governance (ESG).

A growing number of large institutional investors today are incorporating ESG metrics into their capital allocation and stewardship criteria. This shift toward sustainable finance, which has evolved beyond socially responsible investing to include asset management and ownership, has profound implications for investors and companies alike, also for the case of SE Europe.

1

Introduction

Introduction

1.1 Background

The SEEEO is a comprehensive study, which deals with the current energy situation in the SE European region but is also concerned with its "Outlook" from now until 2040. This study is a follow up of similar ''Outlook'' studies published by IENE in 2011 and 2017 (1)(2). The present study covers all 14 countries of the region plus Israel. These countries include: Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Slovenia, Cyprus, North Macedonia, Greece, Hungary, Kosovo, Montenegro, Romania, Serbia, Turkey and Israel. Although strictly not part of SE Europe, Israel, located in the East Mediterranean, is developing increasingly close energy ties with the broader region and hence, it was decided to include it in the current energy assessment. The study also provides essential information on key energy projects in certain important peripheral countries such as Lebanon, Ukraine, Moldova, and Italy.

The energy sector constitutes a major economic activity for most countries in SE Europe with a significant contribution to infrastructure investment and market activity. Even more important is the geopolitical role often associated with energy issues as they normally involve bilateral or even trilateral cooperation. A number of major cross-border energy projects are currently under development in the region, including gas pipelines, electricity interconnections, renewable energy applications (e.g. wind farms, photovoltaic plants, geothermal plants, biomass units, etc.) and large-scale energy efficiency interventions, especially in the building sector.

As we have already pointed out in the previous Outlook studies, SE Europe's geopolitical position is unique as it can be viewed as an energy bridge between eastern supplies and western consumers. Furthermore, the region, especially the Black Sea area and the Eastern Mediterranean, can become a major energy producer with sizable export potential. In this respect, SEE's diplomatic, strategic and economic importance, which also arises from extended electricity and gas interconnections, is carefully documented and analyzed. The study also covers latest developments in key energy areas such as refineries, nuclear power, renewables, energy efficiency, cogeneration and of course electricity and gas markets.

The region of SE Europe is characterized by distinctly different (in terms of structure and operation) and frequently segregated, energy "markets" in various stages of development.

In this sense, the present Outlook undertakes a review of the energy sector, including current and planned policies of individual countries, by focusing on key policy challenges that need to be addressed over the next 5-10 years. The study further attempts to discuss these policy challenges at a regional level and proposes necessary initiatives both as part of the transition process envisaged within the Energy Community[1] *(i.e. electricity and natural gas markets)*, which covers the Western Balkans (3) but also agreed energy policy targets in the case of EU member countries (Greece, Cyprus, Bulgaria, Romania, Croatia, Slovenia, Hungary) and associated ones (i.e. Turkey). In this context, regional gas pipeline projects, electricity interconnections, energy market liberalization issues as well as environmental considerations and the ensuing energy transition are discussed at length.

The sectorial analysis focuses on the region's economies, on its key energy and environmental issues, such as decarbonization, and on the existing legal framework on energy. Furthermore, a detailed examination is undertaken on the following key sectors: oil (upstream, midstream, downstream), natural gas, electricity, renewables, energy efficiency and co-generation, environmental issues, associated technologies and investments. A major part of the study concerns the individual countries of the region and contains a comprehensive energy profile of each one of them. A number of energy maps have also been created, along with comparative data tables and economic analyses.

Given the current state of affairs in SE Europe and the constant flux which characterizes most energy markets and the fact that certain major transnational projects, such as gas pipelines, FSRU-LNG plants and electricity grid connections, have suffered serious drawbacks as a reset of Covid-19 complications, with final investment decisions being constantly postponed, and which are impacting investment in the energy sector as a whole, the study provides some useful insight on background developments, at both government and corporate level. In this context, planned and anticipated investments per country and per sector, together with information on available funding mechanisms, are presented in detail in the final chapter of the study (Chapter 15). The size of this regional market is not insignificant. According to the 'Outlook' findings, the total anticipated energy investments by 2030 for the 15-country group are expected to exceed €430 billion.

1.2 The SE European Region Defined

One of the main aims of the study is to bring together the currently available knowledge on energy developments in the region, including information on energy demand and consumption, an assessment of major energy projects and pursued energy policies as well as trends, estimates and projections of energy demand, supply and investments.

Overall, the scope of the study is to present a critical assessment of the current status of the energy markets at large and at the same time provide an insight on their future developments towards the energy transition.

In addition, the study presents the economic and political background of SE Europe and includes analyses on the dynamics of the regional integration process and the impact of EU expansion on economic development and energy markets. Another important part of the study deals with the energy interconnections across SE Europe, while it analyses the oil, gas and electricity markets and at the same time provides in-depth information on major energy projects in the region (i.e. gas pipelines, electricity grids, nuclear plants, refineries, wind farms, etc.). The study also reports on major developments in the energy market liberalization process as well as on the environmental and energy aspects considerations in SE Europe. Finally, the study besides an analysis and projections of the current and future investment potential identifies business opportunities in the broad energy sector of the region.

A considerable part of the analysis presented in the current "Outlook" report is country related and hence, the need to define carefully and understand the geography of the region is paramount. In order to facilitate our approach, we consider the broader region as consisting of four main blocks, as follows: (a) West Balkans, (b) EU member countries - which include the Eastern Balkans (Romania, Bulgaria, Greece, Hungary) and the north of West Balkans (Croatia, Slovenia), (c) Turkey and (d) the East Mediterranean (Cyprus, Israel).

Inevitably a large part of the aforementioned discussion focuses on the need to upgrade and further expand energy infrastructure, together with priorities on market reforms mainly in electricity and gas. We should nevertheless point out that the Soviet era's economic legacy is still felt in certain countries as considerable part of the region, comprising more than half of its land mass, was until 30 years ago governed by the COMECON framework.

In this sense, the still incomplete process of moving from a centralized type of economy to fully open economy, with all the implications that such a move entails for the energy sector, still presents considerable challenges on economic activity and government policies in some countries in SE Europe. This becomes most visible in the case of Western Balkans, which as it is being pointed out by an IEA survey[2], much of the energy infrastructure was damaged during the conflicts related to the break-up of the Socialist Federal Republic (SFR) of Yugoslavia in the 1990s.

The rebuilding process has been long and difficult and still goes on, alas, amongst continuing distrust within certain communities. Consequently, in these countries energy reforms were initiated at a later stage than other European economies in transition. For instance, electricity systems in some parts of the region still remain extremely fragile and as a result low system reliability and low efficiency impede economic recovery. However, reliable and affordable energy supply is crucial for economic development and social welfare, not only across Western Balkans but for the whole SE European region.

[2] IEA (2018), "Energy in the Western Balkans – The Path to Reform and Reconstruction", https://iea.blob.core.windows.net/assets/6f3556ba-55bc-4d5b-927c-2d027fd2ebfb/Balkans2008.pdf

The present study breaks new ground since with the inclusion of Israel it broadens its East Mediterranean coverage which now comprises Greece, Turkey, Cyprus and Israel. Turkey is an OECD member country, the economy of which, because of its size and dynamism, affects to a large extent financial, trade and energy flows to the rest of SE Europe. The same though cannot be said for Moldova or Ukraine which although energy linked to SE Europe, through electricity and gas interconnections, their economies, far from being integrated, are lagging behind those of other countries in the SE European region. For this reason, these two countries have not been considered in the present Outlook although some basic information is provided on them in Chapter 6 which deals with the peripheral countries.

1.3 The Political Context

Historical Background

Whichever way you look at it, SE Europe is an area which covers a huge geographical expanse of immense cultural diversity and a mosaic of political beliefs where history is still in the making in some areas. An outside observer, who may be tempted to examine the historical background and the relations between the various countries and their people, will soon realise that history is still throwing a heavy shadow on today's world. If one was to start a hypothetical journey transversing the region from the very northwest in Slovenia, then move south to Croatia and then set out to visit the Western Balkans - Montenegro, Albania, North Macedonia, Kosovo, Serbia, Bosnia and Herzegovina - then move further south to Greece and from there northeast to Bulgaria, Romania and Moldova, he or she may soon come across the common historical legacy of this truly wild and intriguing region. A legacy which is non other than the Ottoman Empire where for many years this furthermost area of Europe occupied.

As Mark Mazower very appropriately observes in his acclaimed study on the Balkans (4), successor states – Greece, Bulgaria, Serbia, Romania and Montenegro – had emerged during the nineteenth century as contenders to carve up what remained. Between 1878 and 1908, diplomatic conferences whittled away Ottoman territory, and subjected what remained to Great Power oversight. By the time of the outbreak of the First Balkan War in 1912 which ended Ottoman rule in Europe (outside the immediate hinterland of Constantinople) – the word 'Balkan' had become common currency and was used to describe a rather backward and rich in strife region. The name generally given to that segment is "the Balkan Peninsula" or simply "the Balkans". From the very start, the Balkans was more than a geographical concept. The term, unlike its predecessors, was loaded with negative connotations – of violence, savagery and primitivism – to an extent for which it is hard to find a parallel. "Why 'savage Europe'?" asked the journalist Harry de Windt in his 1907 book of the same name. "Because as the term accurately describes the wild and lawless countries between the Adriatic and Black Seas" (5).

The region's history came to be dominated by revolt and revenge stretching back almost a century and climaxing after 1900 in the terrorist bombings of the VMRO, the Serbian regicide of 1903 and the widespread massacres of 1912-1913 and the ensuing First World War, carried out by all sides. It was no wonder that Europe came to associate the region with violence and bloodshed. A decade of intermittent upheaval ended in 1922 with the decimation of the Greek population in Asia Minor, and the forced population exchange of nearly two million refugees between Greece and Turkey.

If this was not enough the Second World War destroyed the tentative stability of the inter-war period. What re-emerged during the post-war period was Soviet domination, which was contested only by Tito's Yugoslavia (6) and to a lesser extend Albania's Hoja regime after his rapprochement with China in the early 1960s (7). As Mazower puts it, "The Balkans disappeared from Western consciousness during the Cold War, the Iron Curtain ran through southeastern Europe, separating Greece from its Communist neighbors.

Albania became virtually impenetrable. Tito's Yugoslavia was idolized by American policymakers and by the New Left in Europe; the language of international non alignment and of workers' self-management at home fell on receptive ears abroad. Nicolae Ceausescu's rule in Romania was known more for its pronounced anti-Sovietism in foreign policy than for its extreme repression of its own population. In general, Greece became a marginal part of 'the West', while the other Balkan states formed the least studied part of Communist Eastern Europe. Mass tourism brought millions to the region's beaches and ski slopes, and turned peasant culture into after-dinner entertainment. The picturesque replaced the violent, and the worst problems most tourists anticipated were poor roads and unfamiliar toilets" (8).

The collapse of the communist regimes and one-party states in the whole of SE Europe (apart from Greece and Turkey which never came under the iron curtain) in 1989/1990 meant the reshaping of the political order and most importantly resulted in deep changes in the economy. It also meant the end of the old idea of socioeconomic transformation through the domestic policies of the individual state. Accession to the European Union became the single most important political goal for all countries in the region as it meant political stability and market liberalisation with dismantling of tariffs and protected state industries. But it also meant exposure to global competition. Hence, as Mazower points out, "the traditional Balkan nation state is no longer challenged by the old empires; it is not even challenged by the rivalry and hostility of neighbours; it's main threat comes now from the international economy" (9).

An Unstable Region

Almost 20 years after the ending of the Yugoslav wars and 26 years after the signing of the Dayton Accords, which ended the war in Bosnia and Herzegovina, memories in the region are still vivid. The wars were a series of separate but related ethnic conflicts, wars of independence, and insurgencies fought in the former Yugoslavia territory from 1991 to 2001, leading to the breakup of the Yugoslav federation in 1992. Its constituent republics declared independence due to unresolved tensions between ethnic minorities in the new countries, which fueled the wars in the first place.

Often described as Europe's deadliest conflicts since World War II, the Yugoslav Wars were a series of separate but related ethnic conflicts, wars of independence, and insurgencies fought in the former Yugoslavia from 1991 to 2001, leading up to and resulting from the breakup of the Yugoslav federation in 1992. Its constituent republics declared independence due to unresolved tensions between ethnic minorities in the new countries, which fueled the wars. Most of the wars ended through peace accords, the better known of which is the Dayton Accord of December 1995, involving full international recognition of new states, but with a massive human cost and economic damage to the region. Initially the Yugoslav People's Army (JNA) sought to preserve the unity of the whole of Yugoslavia by crushing the secessionist governments, but it increasingly came under the influence of the Serbian government of Slobodan Milošević, which evoked Serbian nationalism to replace the weakening communist system. As a result, the JNA began to lose Slovenes, Croats, Kosovar Albanians, Bosniaks, and Macedonians, and effectively became a Serb army (10).

According to a 1994 United Nations report, the Serb side did not aim to restore Yugoslavia, but to create a "Greater Serbia" from parts of Croatia and Bosnia. Other irredentist movements have also been brought into connection with the wars, such as "Greater Albania" (from Kosovo, though it was abandoned following international diplomacy) and "Greater Croatia" (from parts of Herzegovina, until 1994 when the Washington Agreement ended it) (11).

But apart from the still fresh political and emotional fallout from the Yugoslav wars – most visible in the friction still present today between Serbia, Kosovo and between ethnic communities in Bosnia and Herzegovina - we still have strife conditions and live conflicts in the broader region especially as we move east. The current political and military tensions between Ukraine and Russia, with the involvement of the USA and the EU, is a case in point and is most worrying in terms of regional stability, while Turkey's open support to Azerbaijan in its dispute with Armenia, over the Nagorno-Karabakh issue, has resulted in renewed warfare (summer 2021) adding a further point of friction. In addition, we have Ankara's repeated challenging of Cyprus and Greece over seabed rights and their Economic Exclusion Zones (EEZ) in the Aegean and the East Mediterranean which has given rise to renewed tensions and to which we refer to in Chapter 4.

Current Issues

Reference to the Yugoslav Wars and their outcome in terms of human loss and the new political reality which came about with the emergence of seven separate states (Slovenia, Croatia, Bosnia and Herzegovina, Serbia, Montenegro, North Macedonia and Kosovo) and the open issues related to geographical borders and EEZ, is both useful and necessary if we are to understand the current political milieu and the new challenges facing the region. Although the fear of an open military conflict between neighbouring countries in the region still hangs on the air, it seems that the most important challenges facing governments across SEE are related more to economic and energy issues, which of late, as prices have been rising throughout 2021, have come to dominate the economic agenda.

In this context, one has to read through the plans and aspirations expressed by the new states which appear to originate more from a deep sense political insecurity which they inherited following the breakup of rump Yugoslavia, rather than their urge for fast and uncompromising economic development. Hence, the common desire to join the European Union - already materialised in the case of Slovenia and Croatia - which they see as a bastion of stability, lawfulness and economic anchor.

Consequently, any delays or impediments in the accession process of West Balkans give rise to protests and friction usually addressed to neighbours but also to EU's leadership. The case of Serbia is most relevant in this debate since the country appears to be the most advanced in its negotiations as it is officially a candidate country and is already in negotiations with Brussels.

Lately, Serbia has taken a step toward in its goal of joining the EU by opening talks on four policy areas, but European officials warn Belgrade that progress in the process still depends on continued reforms and normalizing relations with Kosovo. To be eligible to join the 27-country EU, applicant states must bring their laws and regulations into line with the bloc's standards through negotiations in 35 policy areas, or chapters, including finance, agriculture, transport, energy, social, and justice policy.

The EU established a regional approach to the Western Balkans in 1997, with political and economic conditionality criteria for the development of bilateral relations. On 6 February 2018, the European Commission published its expansion plan to cover up to six Western Balkan countries: Albania, Bosnia & Herzegovina, Kosovo, Montenegro, North Macedonia, and Serbia. The plan envisages that all six applicants could achieve accession as members of the European Union after 2025. The most advanced of the above candidate countries for accession to the EU is Serbia.

On December 14 2021, Serbia was allowed to open talks on climate change and environment, energy, transport policy, and trans-European infrastructure networks - the first time the Balkan country has opened four chapters at once. Belgrade has now opened 22 negotiating chapters since its membership talks began in 2014. "Serbia is taking yet another very important step forward joining the European Union," EU Enlargement Negotiations Commissioner Oliver Varhelyi said following the intergovernmental conference with Serbia in Brussels.

Gasper Dovzan, state secretary at the Slovenian Foreign Ministry, whose country is (second half of 2021) holding the presidency of the EU Council, said that the Serbian government "prioritized EU-related reforms and delivered on a number of important commitments, in particular on taxation and energy." But "further efforts are needed," Dovzan said, citing judiciary independence, media freedom, and the fight against corruption and organized crime. "Serbia's progress on the rule of law and the normalization of relations with Kosovo remains essential and will continue to determine the overall pace of the negotiations," he added (12). Kosovo declared independence from Serbia in 2008 after a 1998-99 conflict between ethnic Albanian separatists and Serbian forces. The war ended after a 78-day NATO air campaign drove Serbian troops out, and a peacekeeping force moved in. Kosovo's independence has been recognized by more than 100 countries including the United States and all but five of the EU member states. But Serbia still considers the territory a southern province and is supported by Russia and China. EU-mediated talks between Pristina and Belgrade to settle their differences have stalled.

Next in line for opening accession talks with the EU is **North Macedonia**. Despite the hopes raised by France's support for opening membership talks with Albania and North Macedonia, the European Union once again delayed matters. "The Council looks forward to the holding of the first intergovernmental conference [with Albania and North Macedonia] as soon as possible," stated the General Affairs Council's conclusions on December 14. The main reason for the delay, for a second year in a row, was Bulgaria's block on North Macedonia's EU path over an unresolved history and identity dispute. Sofia insists on Skopje accepting a de facto Bulgarian identity that centres around the claim that the North Macedonian identity and language are of Bulgarian origin.

The EU has in recent years tied Albanian talks to those of North Macedonia, so both countries are delayed.

North Macedonia's government narrowly avoided collapse on November 11 2021, partly on account of the EU membership issue. The ruling social democrats (SDSM) avoided a parliamentary confidence vote they would have lost, when a member of the ruling coalition went into hiding. The MP, who belonged to the ethnic Albanian party Besa, was expected to vote against the government and join the opposition. The opposition VMRO-DPMNE conservatives called for the confidence vote after seizing 42 of the country's 58 town halls in nationwide local elections on October 31, 2021. Prime minister Zoran Zaev initially said he had lost the people's confidence and would resign, but he later postponed that resignation indefinitely (finally he was resigned in December 2021). North Macedonians are disillusioned by the lack of progress towards EU membership.

The Zaev government had assured them that EU membership would follow a 2018 agreement that changed the country's name following objections by EU member Greece to 'Republic of Macedonia'. The 2018 deal did allow North Macedonia to enter NATO immediately (13). The new government in Sofia (December 2021) has signaled that it intends to normalize relations and lift some its objections (14).

When it comes to the rest of the West Balkan countries the prospect of opening accession talks with Brussels looks increasingly remote given a number of still unresolved problems ranging from territorial issues, to rule of law issues and economic and environmental issues. **Kosovo's** case seems the more acute since in order to ensure stability at the territory and neutral rule of law enforcement, the EU is operating in Kosovo under the umbrella of the United Nations Interim Administration Mission in Kosovo (UNMIK), deploying police and civilian resources under the European Union Rule of Law Mission (EULEX). The Stabilisation and Association Agreement (SAA) between the EU and Kosovo was signed on 26 February 2016 and went into force on 1 April 2016.

Another difficult case when it comes to EU accession is **Bosnia and Herzegovina**. Although the country formally applied for EU membership in February 2016, following years of constitutional reforms and engagements arising from the Dayton Peace Agreement, serious unresolved problems related to the functioning of government remain. The official EU position is that it remains a potential candidate country until it can successfully answer all of the questions on the European Commission's questionnaire sheet as well as "ensure the functioning of the Stabilisation and Association Parliamentary Committee and develop a national programme for the adoption of the EU acquis". Many observers estimate that Bosnia and Herzegovina is at the bottom in terms of EU integration among the Western Balkans states seeking EU membership.

Like the other countries in the West Balkans, **Albania's** drive to join the EU remains strong and the country has indeed managed to overcome several obstacles in its accession path. Successive governments in Tirana see their country's future firmly in the hold of the EU with which they have a growing trade relationship. Following recognition as "a potential candidate country in 2000", Albania followed in the steps of other candidate countries and has been extensively engaged with EU institutions and joined NATO in 2009. The full adaptation of European Acquis in Albania's energy market regulation is a cornerstone of Tirana's energy policy while it seeks full participation in EU energy market mechanisms such as the Target Model and the operation of an Energy Exchange.

On 23 June 2014, under the Greek EU Presidency, the Council of the European Union agreed to grant Albania candidate status, which was endorsed by the European Council a few days later. Albania's EU accession is bundled with North Macedonia's EU accession. Albania is given certain pre-conditions for starting the accession negotiations, such as passing reforms in the justice system, a new electoral law, opening trials for corrupt judges and the respect of human rights for its Greek minority. In May 2019, European Commissioner Johannes Hahn reiterated this recommendation. Eventually, on 25 March 2020, the Council of the European Union decided to open accession negotiations, which was endorsed by the European Council the following day (15). Montenegro seems to be one of the most likely candidates in the region for EU accession in this decade. The negotiations with Montenegro started in 2012 and as of 2020 32 of 35 chapters had been opened for negotiation. Thus, most of the chapters have already been opened and some have been provisionally closed. In March 2021, the chief negotiator for Montenegro announced that the country aims to fulfil all requirements by 2025. The European Council outlined some of the main areas in need of reform in a 2019 report. These areas are the rule of law, corruption, public administration reform and freedom of expression.

Turkey

EU-Turkey relations have been tense since late 2000s, as Turkey's accession process with the EU began to slow down and political and economic reforms in the country came to a halt. The EU and Turkey have divergent views over several issues, e.g. the eastern Mediterranean, the Cyprus issue, regional conflicts, such as Libya and Syria, and democratic standards. For instance, Turkey criticized the EU over stalled accession talks on December 17, 2021, saying that the bloc's policies are "detached from reality" and "based on ideological motives"[3]. The General Affairs Council of the EU expressed a few days earlier its concern over Turkey's democracy, rule of law and fundamental rights, adding that "Turkey's accession negotiations effectively have come to a standstill and no further chapters can be considered for opening or closing". The Turkish Foreign Ministry said in a statement that the decisions adopted by the EU have shown once again that the bloc approaches enlargement within the framework of "membership solidarity, not from a strategic perspective". EU relations apart, Turkey's real goals and aspirations are aimed at regional, if not global, level. President Erdogan's power play involves the projection of Turkish power over a very large geographical area, stretching from North and West Africa to the Gulf region, to Somalia, the Caspian Sea and Pakistan. His vision is not confined to SEE and the Mediterranean but encompasses a much larger sphere of influence. Energy, in all its forms, plays key role in Turkey's expansionary plans, especially as it relies at a very high degree on oil and gas imports. However, this grand vision is not currently supported by a robust economy as the Turkish lira has been on a constant downfall over the last two to three years, having lost 57% of its value since the beginning of 2021.

Apart from the EU, which is Turkey's most important export market and main source of investment, relations are also at a low point with the United States, which reached an all-time low. Turkey's dependence on capital inflows means that a sudden change in the risk appetite of investors can have a significant negative impact on macroeconomic indicators.

As an illustration of the problem, in 2018, when US President Trump on Twitter threatened Ankara with sanctions, this led to a sharp depreciation of the lira, after which the economy stagnated.

However, one of the most important issues (if not a top priority) that Turkey has to deal with is its ominous current economic situation. The global financial crisis of 2008 hit the country's economy hard. In the aftermath of the financial crisis, quantitative easing by the major central banks caused a large flow of capital into emerging markets, which Turkey benefited from. This led to a rapid expansion of credit in the country, much of it channeled to the construction and real-estate sectors. The economy continued to grow at high rates, but the low rate of savings - one long-standing vulnerability - did not improve. As a result, the economy remained dependent on capital inflows or "hot" money from abroad, mostly in the form of short-term capital.

This led to an escalation of private debt denominated in the US dollar. When the coronavirus pandemic struck in 2020, Turkey was already suffering from a record depreciation of the lira and a depletion of foreign-exchange reserves to counter this, as well as from double-digit inflation for the previous two years. The pandemic has further deepened the country's economic difficulties. The turmoil has caused a strong downward spiral of the lira and inflation has fluctuated in the double digits, standing at 20% and more. The official unemployment rate exceeded 13% and youth unemployment 25% in 2020[4] .

Turkish president Recep Tayyip Erdogan's defence of recent interest rate cuts and a declaration of an "economic war of independence" has sent the lira plunging and left analysts wondering how much further he is willing to let the currency fall. Erdogan, who has sacked three central bank governors since mid-2019 and is a life-long opponent of high interest rates, has insisted that he will continue on the path of low rates in a quest to stimulate growth and investment, as a recent article by the Financial Times highlights[5].

The Energy Angle

Over the last twenty years or so, as reconstruction gathered pace in Balkans and as new EU members states (i.e. Slovenia, Croatia, Bulgaria and Romania) were finding

their bearings within the single market, energy emerged as a key factor and a strong cohesive force capable of forging together disparate interests and in promoting economic activities which simply could not otherwise develop. It is in SE Europe more than anywhere else that one realizes that economic activity cannot advance without abundant and relatively cheap (i.e. affordable) amounts of energy. The repositioning or rebranding of the region (as many neoliberals like to call it) as SE Europe is on the one hand contributing in taking a fresh look in the broader geographical area, and on the other helps define it in economic terms, where energy has emerged as a basic consistent and vital part in the functioning of the economies of the various countries. In addition to its role in economic development, energy provides a much-needed link between the various countries. The re-emerge of SE Europe as a new geopolitical block has also far-reaching implications in terms of social and economic development, especially in view of its closer economic and political ties to the European Union. A major consideration, as we shall see in the chapters which follow, when it comes to studying and analyzing the energy issues involved.

In this context, one should observe that the closer the countries of the SEE area get to the EU, either by membership or association, the less becomes the direct influence that traditional players in the region, such as Russia, Germany and China (read Albania). Also, following the Dayton Accord USA's influence in the region has been strong, especially in Western Balkans. We should remember though that Russian influence is still present in countries like Serbia, Romania, Bulgaria and North Macedonia because of religion, cultural ties and until very recently language.

With all of these countries relying mostly on Russia for their gas import needs (with the exception of Romania which is becoming increasingly self-sufficient thanks to its own gas reserves), the links with Moscow still remain strong. The entry of China in the region, almost 15 years ago, as a major trade and technology partner has been slow and steady.

The crux of Chinese influence is largely focused on energy and infrastructure through the provision of funding for new power stations and electricity grids.,

However, concerns over China's investments in SE Europe are not just limited to its coal drive, against EU stated decarbonization policies, but spring from worries of the financial consequences of overexposure of SE European economies to Chinese investments. As the Economist noted in 2019 (16), there are concerns about the financial consequences of the Belt and Road Initiative (BRI). The most extreme is that the scheme involves what is pithily described as "debt-trap diplomacy". In this view, China is deliberately overloading weak countries with loans; when they buckle, it seizes their assets and influences their politics. Currently, in SE Europe, a number of coal-fired power plants have attracted strong Chinese interest as they already form part of pursued national energy policies by a number of countries, as several EU enlargement countries in the Western Balkans, such as Bosnia and Herzegovina, Serbia and Kosovo, plan to build new lignite-fired power plants.

These coal projects are not compliant with the Paris Agreement's aim of limiting climate change at least to 1.5°C but readily available Chinese money is enabling them to proceed. As the international financial institutions have phased out direct coal financing, most of the plants are slated for loans from the state-owned China Eximbank or other Chinese public banks. Up to 3.5 GW of coal-fired power plants may be built in SE Europe in the current decade with Chinese financial support, based on CEE Bankwatch Network's estimates (17).

Beijing's ambitious plans to play key role in SE Europe as an alternative economic influence, besides the EU, Russia and the USA, have at present been stalled following sharp reaction from Brussels and Washington over the last two years; especially as China's predatory plans in this part of the world have come under increased criticism and investment plans are being carefully scrutinised.

This change of attitude towards Beijing follows the deeper rift and negative environment in economic and trade relations between Washington and Beijing which has come about as Chinese technology firms motives are increasingly being questioned on security grounds by both the US government but also by the UK and the EU. This does not necessarily mean that Beijing's geopolitical ambitions in the region have come to an abrupt end. However, at present China's geopolitical play in SEE is being seriously questioned and remains to be seen if and when Beijing will wish to reestablish a stronger presence (18). The present study is structured in such a way as to provide both a penetrating glance but also an overview of the energy scene in the SE European area. By means of detailed country and sectorial analysis, the region's rich energy resources base is identified and the efforts to tap it are described. Also, the present shortcomings in the structure of the current energy mix are recognized while forecasts are made, supported by modeling, of anticipated energy demand and supply for the various countries but also for the region as a whole. In addition, SE European energy related investment potential and outlook is identified together with the appropriate strategies and policies, which will enable actual investments to be realized while aiming at a more equitable utilization of the region's resources. Another important policy parameter, which comes out strongly in this study, is energy security, which clearly has huge political implications. Indeed, maximizing the utilization of indigenous energy resources, both conventional and alternative ones in parallel with strong interconnections and optimization of energy imports could enhance energy security and help reduce the region's carbon footprint. Chapter 4 provides a detailed analysis on the region's energy security issues.

As the region traditionally has lagged behind main European trends, only to catch up enthusiastically years later, now it seems to be racing ahead of time in an effort to take advantage of a new wave of reforms in the offing. This is most evident in the case of energy where thanks to latest advances in information technology (e.g the internet) and digitalization the region is embracing fast the tenets involved in energy transition aspiring to cleaner forms of energy.

Although energy transition, in the case of EU member countries, has become of late official government policy and clearly embedded in their national energy plans it does not yet enjoy wide acceptance among the population and industry which seem very uncomfortable with rising energy prices. The situation, as we commented earlier in the chapter, is worse in the case of Western Balkans as official government policy on energy by a number of countries considerably diverges from that of the EU. Yet, the fast forward drive towards a future of clean energy and lesser dependence on traditional oil and gas imports may be challenged as a result of yet unresolved border and governance issues going back to centuries' old conflicts and antagonism.

1.4 Focus on Western Balkans

The Dual Transition of the Western Balkans

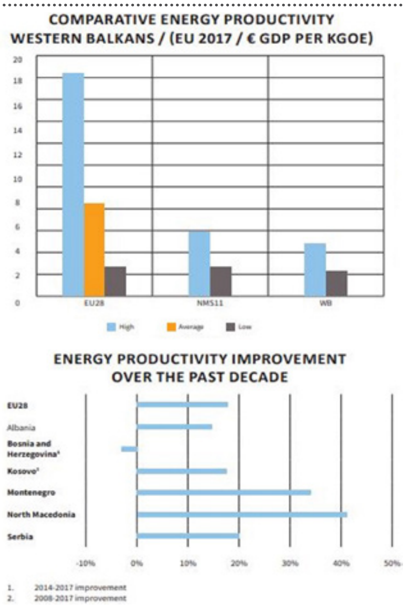
The case of Western Balkans merits special attention since the energy sector faces a unique dual transition, a challenge without any precedent in the industry: transition from centralised state-controlled systems to open and competitive markets, and at the same time transition towards decarbonisation.

Participation in the Energy Community Treaty, which aims at extending the EU internal energy market rules and principles to countries in SE Europe and beyond, provides a clear policy framework but the task remains considerable. As it is pointed out in the recent Western Balkans Investment Framework (WBIF) Clean Energy Factsheet[6], the sector is characterized by limited market mechanisms and private sector's participation, insufficient and aging infrastructure, high reliance on fossil fuels, late adoption of renewables beyond hydropower and residential biomass, limited energy

[6] WBIF (2021), "Clean Energy", https://www.wbif.eu/storage/app/media/Library/FactSheets/Sector%20Factsheets%20 2021/WBIF%20ENE%20Factsheet%20Nov%202021.pdf

efficiency and energy productivity, and high rates of energy poverty despite usually high levels of direct and hidden energy subsidies (mostly targeted towards fossil fuels). Similar to other transition economies, the Western Balkans emerged from the socialist era with low energy productivity. Significant but uneven progress was made over the past 10 years and the gap with transition economies among EU Member States is moderate. However, the highest regional achiever remains at approximately half of the EU average of €8.27/ Kgoe. Montenegro and North Macedonia have improved the most at twice the average EU speed; Kosovo and Serbia have largely matched average EU progress; Albania has somewhat lagged behind; while Bosnia and Herzegovina has not shown improvement over the shorter period for which data is available, the WBIF study [7] supports.

Figures 1.2 & 1.3 **Comparative Energy Productivity in the Western Balkans** *(above)* **and Energy Productivity Improvement over the Past Decade** *(below)*



Source: WBIF

Furthermore, reliance on low-grade lignite in power generation in most countries in the region adversely affects air quality (and acid rain), not only in the region but also in neighbouring countries, with reduced life expectancy and increased health costs as consequences. The region is home to eight of the ten most polluting plants in Europe and the sixteen coal plants located in the Western Balkans perform poorly compared to the 250 coal plants active in the European Union according to a 2016 study[8]. The same study estimated induced annual health damages from coal plants at a minimum of €1.2 billion for the region alone. Problems are particularly acute in North Macedonia or Bosnia and Herzegovina, where Skopje, Tetovo or Tuzla usually rank among the worst cities in Europe for air quality. B&H and North Macedonia's air pollution can be attributed to emissions from the industries, loosely regulated vehicles, the burning of outdoor waste and domestic heating.

Table 1.1 **Total Emissions of Main Pollutants by Coal Power Plants in the Western Balkans and the EU**

Total emissions of main pollutants by coal power plants in the Western Balkans and the EU			
	SO2 (t/year)	NOx (t/year)	PM 2.5 (t/year)
EU-28*	992,248	795,358	11,946
Western Balkans**	750,893	120,012	20,188

** Only 22 EU countries have coal power plants*

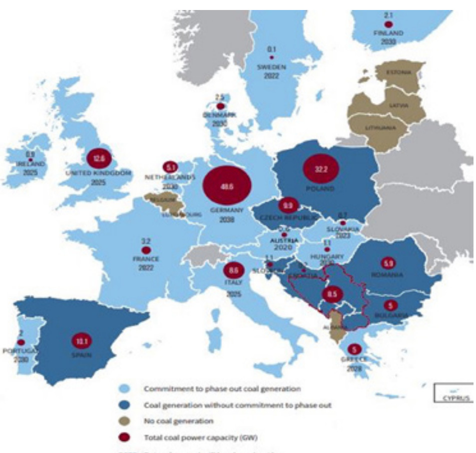
Map 1.3 **Western Balkans Coal-Fired Power Generation, A European Perspective**



[7] WBIF (2019), "Investing in Clean Energy in the Western Balkans", https://wbif.eu/storage/app/media/Library/9.Sectors/1.Energy/EE%20Brochure%20final%20dec%202019.pdf

[8] HEAL (2016), "The Unpaid Health Bill - How Coal Power Plants in the Western Balkans Make us Sick", https://www.env-health.org/IMG/pdf/heal_report_the_unpaid_health_bill_how_coal_power_plants_make_us_sick_final.pdf

Although current energy consumption per capita is approximately half than in the European Union, economic development should lead to an increase in consumption, both through development of manufacturing and through increased consumption in the residential sector as comfort levels rise. Decarbonising the regional energy sector thus emerge as a key challenge to reduce emissions and improve air quality. There is a substantial RES potential to help in the process. For instance, a WBIF study on Sustainable Hydropower in the region[9] identified about 50 projects in the sector (refurbishment/upgrade/greenfield) worth further analysis. In addition, IRENA estimates that capacities of 12.2 GW of wind and 4.4 GW of solar PV could be cost competitive in the region today if the cost of capital was in line with that observed in neighbouring Croatia, Hungary, and Romania. Current total generation capacity in the region is 18.6 GW, including approximately half from coal, as the WBIF (2019) study notes.

However, and unlike most EU countries, certain Western Balkan countries (i.e. Serbia, Kosovo, Bosnia Herzegovina) have not yet committed in phasing out coal but instead plan to add significant new coal power capacity by 2030, in contradiction with commitments under the Energy Community Treaty and increasing regulatory drift from the EU. But their governments (not without reason) insist that only coal, an indigenous resource, can provide energy security and guarantee affordable electricity prices.

Action is needed in the transport sector too where the dominance of road transport and an ageing vehicle fleet are contribution to both emissions and air pollution. For instance, almost 80% of registered cars in Bosnia and Herzegovina are over 15 years old, making the country's car fleet one of the oldest in Europe. Efforts however have been limited beyond investment in Trans European Network rail corridors and bans on importing ageing second hand vehicles.

The picture is brighter for energy efficiency for which significant efforts have been deployed over the past 10 years and spearheaded by the Energy Community, IFIs and donors (Details are presented in Chapter 12 of the Outlook study). However, much remains to be done in particular in the public sector which has been set unchallenging targets for its large building stock or in the residential sector where sustained efforts started only fairly recently.

If the portfolio of projects that have received some EU support over the period is a reliable guide, these efforts have been fruitful. As a rule of thumb, the portfolio shows that €1 million in clean energy investments can be expected to generate primary energy savings in excess of 2,000 MWh and emissions savings in excess of 1,000 tons, while sustaining employment estimated at more than 11.75 person years.

As the same study highlights, "Decarbonisation and energy efficiency are often seen as costs but it is clear that they could become drivers for regional growth through (i) building up on successful energy efficiency efforts in the region which have proven their economic viability; (ii) utilisation of a large untapped renewable energy potential; (iii) addressing the policy challenge and the health costs of a large coal-fired generation sectors and (iv) the induced effect on economies of a more reliable, more competitive and cleaner energy supply as well as of a healthier population".

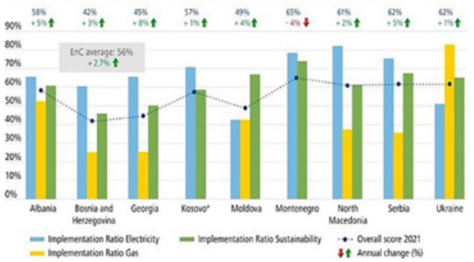
Energy Transition Slows in the Western Balkans

According to the Energy Community Secretariat's Annual Implementation Report for 2021 (19), its contracting parties achieved only modest progress in reforming their energy and climate sectors over the last two years (2020-2021). Montenegro, which still has the best score, was the only country that reversed its gains in 2020, as it is late with the overhauling of the Pljevlja coal plant.

9 WBIF (2017), "Regional Strategy for Sustainable Hydropower in the Western Balkans", https://www.wbif.eu/storage/app/media/Library/10.Projects/1.Hydropower/21%20WBEC-REG-ENE-01-Final-Report-05.12a.pdf

The overall pace of reform within the Energy Community was halved in the past year. The total implementation score increased to 56% from 53%. In the Western Balkans, only Albania and Serbia had growth above the overall average, both gaining five percentage points to 58% and 62%, respectively.

Figure 1.4 **Overview of Implementation Performance by Contracting Parties**

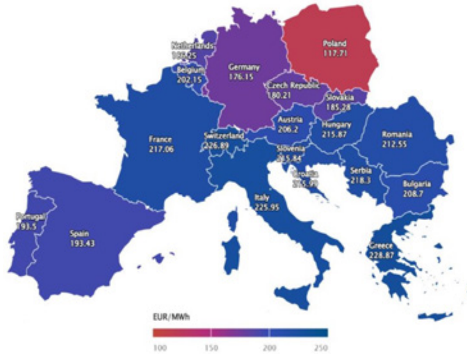


Source: Energy Community Secretariat

The Energy Community report shows that regional power market integration remains one of the biggest challenges. The gap in the implementation of the European legislative package on capacity allocation, balancing and system operation remains high on the priority list. "Without the further integration of their power sectors, the domestic markets, which are all of small scale, with the exception of Ukraine, will remain sub-optimal and unable to facilitate the transition towards a decarbonized and decentralized electricity sector. The region must prepare for the large-scale deployment of variable renewable energy sources," Deputy Director Dirk Buschle said (7). For now, domestic lignite and coal-generated power are again in high demand, Kopač and Buschle warned and asked the contracting parties to stay focused on decarbonization.

According to the report, Serbia (which is not market coupled), recently experienced the highest electricity prices in Europe for several days on its day-ahead market. Furthermore, the report says that small, isolated markets are more prone to price volatility. Although the reverse is not necessarily true as recent experience shows since as fully coupled markets experienced very high prices in November and December 2021 (see Map 1.4).

Map 1.4 **Day-ahead Electricity Prices in Europe (November 2021)**



Source: Energy Live

The contracting parties that have coal in their energy mix are still struggling to comply with the emission ceilings established under their national emission reduction plans (NERPs). Albania doesn't have any coal mines or plants using the fossil fuel. Nevertheless, there was at least some progress in all major areas in the Western Balkan contracting parties, with the exception of gas regulations in Bosnia and Herzegovina. With a share of 21.4% of renewable energy sources in 2019, Serbia was still far from its overall indicative trajectory of 25.6% in 2019, and the target for 2020 was 27%, while reforms in the gas sector are at an early stage.

"Government announcements of possible interventions in their energy sector in response to the crisis could further fuel the energy prices. While interventions are legitimate to the extent they address the impact of the price hike and protect vulnerable customers, they become problematic when such interventions are not proportionate in scope or in time, and when the reforms of energy market governance, having sometimes only recently been aligned with the European Union's, are being called into question," the report reads.

The secretariat acknowledged more support is necessary – a Green Marshall Fund for the Energy Community – to make sure that the transformation is feasible and just. According to the document, the contracting parties have ways to go carbon pricing, "arguably the most effective instrument in the Green Deal's regulatory toolbox."

As far as the electricity market is concerned, Albania has yet to establish a spot market for electricity, the report notes. As long as there is no power exchange, competition is distorted by a public service obligation. All customers below 35 kV continue to be supplied by the universal supplier at regulated prices without the possibility of switching. Transmission system operator unbundling in Bosnia and Herzegovina is not in line with the provisions of the Third Energy Package. Legal unbundling of the distribution system operators in the Republic of Srpska was completed, but not in the Federation of Bosnia and Herzegovina. The country almost completed implementation in the statistics sector. On the other hand, work in the gas sector is still at an early stage.

Kosovo ranks best in the infrastructure sector, where the implementation is almost completed, but the secretariat said market liberalization has stalled. Montenegro's progress in renewable energy in transport is relatively high, at 28% and implementation in the energy efficiency sector is almost complete. There are lags in the areas of oil, gas and infrastructure. However, Montenegro still has no gas network. North Macedonia was praised for committing to phase out coal by 2028 but the report shows it has done little in terms of power market reform. Reforms in the infrastructure sector are yet to begin. Serbia upgraded its legal framework in the sectors of climate, energy efficiency, electricity and renewables but its track record continues to be weighed down by its failure to unbundle all of its transmission system operators as required by the Third Energy Package, the Energy Community Secretariat said.

Carbon Pricing

According to former Energy Community Director Janez Kopac, the lack of carbon pricing mechanisms threatens the contracting parties' long-term integration with EU markets. Speaking to ICIS[10], Mr. Kopac said the uptake of the EU's Third Energy Package – which requires EU members states to create competitive, transparent markets – has been increasing in all nine Energy Community states in recent years, with the exception of Bosnia and Herzegovina, which has constitutional issues that need to be solved first. "The best [in transposing and implementing EU rules] have been Montenegro and North Macedonia for electricity and Ukraine for natural gas," he said, shortly after the launch of the Energy Community's annual implementation report on November 15, 2021. Mr. Kopac further noted that the key to success had been the trust that the Energy Community Secretariat has earned thanks to its independence. For example, he said the North Macedonian government refrained from intervening in the electricity market because the country imports most of its electricity. In Montenegro's case, there was a pressing need to reform because the country built a subsea electricity cable to Italy. Finally, Ukraine had to liberalise its natural gas market as part of credit arrangement with the International Monetary Fund and in order to secure a long-term gas transit agreement with Russia in 2019.

The biggest difficulty ahead, says Mr. Kopac, lies in a growing rift between Energy Community and EU countries caused by misalignment of the adoption of a carbon pricing mechanism. The adoption of such a mechanism is voluntary and so far only Montenegro adopted a credible carbon price of €24.00/tCO_2e. "The commission is the only body that can propose new elements of EU Acquis for the transposition in the Energy Community and it seems that an emission trading scheme will be proposed sometime around 2025. Contracting parties could be more active by themselves but right now they are waiting for the EU to push them with legal action".

While most contracting parties are lagging behind EU member states in pursuing a viable carbon pricing mechanism, many are still forking out subsidies for coal-fired capacity. "The Energy Community Secretariat identified

[10] ICIS (2021), "Energy Community countries' energy regulation more aligned with EU", https://www.icis.com/explore/resources/news/2021/11/16/10706271/energy-community-countries-energy-regulation-more-aligned-with-eu

several potential illegal state aid cases in the contracting parties. We urged all national authorities and the Competition directorate to act but all we received instead was silence," Kopac added.

Some contracting parties, such as Bosnia and Herzegovina, Serbia or Kosovo, which have strong coal dependency, are simply not planning to phase it out until 2050, despite promises for the provision of national climate funds that would be co-managed by the EU and national authorities in a bid to help speed up the decarbonization process. Obviously the above three countries consider coal and lignite to be an indispensable part of their energy security arrangements and hence, they are not willing to endanger fulfillment of their power requirements in exchange of dubious substitutes and the blurred vision of a far in the future carbon neutrality. This seems to be the position of many countries in SE Europe as energy security ranks very high in their overall energy policy.

Market Integration

Another major challenge ahead for Western Balkans is ensuring that governments remain compliant with EU regulations and pursue the integration of their markets. According to Energy Community officials, the current energy crisis had been used to justify governmental price interventions in Serbia, Albania, as well as the Ukrainian gas markets, but also in some EU countries. "As long as markets are not fit for purpose, there will always be the same excuse. [Governments must] stop intervening in electricity and gas incumbents' activities by adopting indirect regulation that leads to never ending cross-subsidisation," note the above officials, pointing out that in some cases governments use the pretext of security of supply to justify unviable economic measures.

There is obviously a need for deeper integration of contracting parties with EU states, but momentum has been lost and any prospects for treaty amendments have hit the buffers.

Energy Community officials underline that Contracting Parties which are expecting to extend the shelf life of their assets operating on natural gas should consider fast-tracking their transition to cleaner forms of generation by attracting more investments in renewables. "Building new gas infrastructure now could be stranded assets very soon," points out Mr. Kopac. Needless to say that such views are not shared by most governments in the region for reasons already explained.

1.5 The Evolving SEE Energy Landscape

A cursory examination of the basic economic and energy statistics will reveal the great disparities that exist between the various countries. There are marked differences over a wide spectrum of economic and social parameters to an extent that makes one wonder if there is any merit in pursuing a common stand in the hope of establishing integrated strategies for the area.

On the other hand, it is evident that the relatively small and fragmented states of SE Europe, especially in Western Balkans, cannot move alone and truly pursue independent economic, let alone energy policies. Even the largest states of the region, such as Turkey, which enjoys a strong geopolitical position and is driven by a big economy, needs to develop close ties and partake into the energy policies of neighboring countries, like Bulgaria and Greece, in order to advance its own energy interests.

Thus, a sense of interdependence becomes inevitable. As a result, all countries have their eyes set towards the broader region of SE Europe where the development of meaningful economic relations and cooperation, based on mutually beneficial policies, have energy as their common denominator.

However, one should adopt a realistic approach when investigating the energy situation of the region by identifying at an early stage the serious imbalances that exist between the East and West Balkans in terms of energy demand, supply and infrastructure. As part of our integrated examination of the peculiarities of SE Europe, we must single out Turkey, whose position, because of its size (much bigger than any of the other state of the region) and geographical position has to be viewed in context. Turkey's role, in relation to the rest of SE European countries, in the forging of common energy strategies and energy market integration (in both electricity and gas) is as important as that of Greece in influencing the developments in the rest of the region.

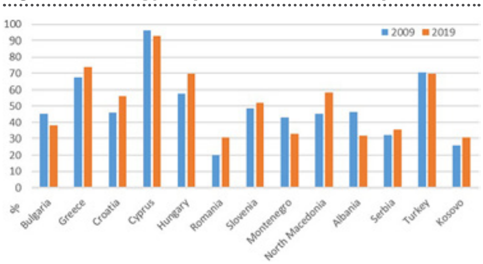
The abbreviated energy data for the region, as shown on Figure 1.5, which includes the gross inland consumption for a representative group of countries, can help us understand the region's widely diverse energy scene. This is characterized not only by huge market disparities in terms of population, economic development and energy infrastructure (e.g. installed electricity capacity, gas use, oil consumption), but also by the region's great dependence on energy imports (see Figure 1.6).

Figure 1.5 **Gross Inland Consumption in Selected SEE Countries**

	Bulgaria	Greece	Croatia	Hungary	Romania	Serbia	Turkey
2009	17.571,000	30.339,396	9.569,836	25.840,354	34.791,721	15.230,394	99.721,049
2019	18.847,668	23.551,592	8.790,716	26.708,150	33.205,199	15.420,374	150.123,29

Sources: Eurostat, IENE

Figure 1.6 **Energy Dependence in SE Europe**



Sources: Eurostat, IENE

Indeed the region's overdependence on energy imports is a defining characteristic of its economy and in that respect considerable emphasis is given in the present "Outlook" on the negative economic impact from substantial oil and gas imports but also on the efforts currently in place to develop further indigenous hydrocarbon production and promote RES utilization (see Chapters 8 and 11 respectively).

SE Europe is strategically located between the hydrocarbon-rich regions of the Middle East and the Caspian basin, including Russia, and the big energy-consuming states of Western and Central Europe. Even with the prospect of an accelerated decarbonization in the years to come, this observation is still valid as gas will for the foreseeable future provide much needed base load for power generation for most countries in the region. Thus, the region is well positioned to play an important role, as an energy bridge in the transiting of hydrocarbon resources and in the diversification of oil and gas supplies, both within the region itself and for Europe as a whole, despite the fact that due to the coronavirus pandemic, which still exists, hydrocarbon exploration activities have been limited globally and regionally.

At present, gas markets in the East Balkans, although in existence for many years, are still at an early stage of truly commercial development, while those in Western Balkans are small, and in some areas non-existent, but have an excellent potential for growth, especially now where new gas pipeline projects, including Turk Stream and the TAP-TANAP system, are currently in operation. It remains to be seen though if gas will manage to enter the energy mix of countries like Albania, Kosovo and Montenegro which have no gas infrastructure at all, as strong opposing forces, within the EU mechanism, argue that a straight leap into renewables is not only preferable but desirable in the context of energy transition and long-term carbon neutrality.

However, such arguments are not at all convincing to the political leaderships of the above countries which see the entry of gas into their systems as the fastest and easiest way to lower emissions and also increase security supply by diversifying their energy mix. It should also be noted as a general observation that many countries in the region depend heavily on indigenous coal and lignite for power generation and will continue to do so for some years to come.

Decarbonization targets vary between 2028 in the case of Greece to 2040 in the case of Bulgaria and 2050 for Serbia. Cost-effective expansion of generating capacity would produce a more diversified mixture, including new technologies with a lot more efficient and cleaner lignite power plants (producing less CO_2 emissions), use of CCUS technologies, gas-fired combined cycle and CHP, nuclear power, and renewables, including hydropower, with the balance being determined by the prevailing prices for fuel and CO_2 emissions. This would support a more sustainable energy mix for the region with reduced carbon emissions and a lower overall energy intensity.

The energy mix for SE Europe as a whole for 2000, 2009 and 2019, with and without Turkey, is presented in Figures 1.7-1.12. In our various calculations, a distinction is made as to Turkey's participation (with and without Turkey) as the country's size and energy magnitudes are significant in comparison with those of other countries in the region and therefore if seen together with the East and West Balkan region, they tend to distort the overall picture. Drawing comparisons between the energy mixes in SEE between 2000, 2009 and 2019, either with or without Turkey, we are forced to admit that there appears to be a strong inertia with regard to change as oil and solid fuels appear to maintain their dominant position throughout the 20-year period. Including Turkey, solid fuels in SE Europe still correspond to a very strong 24% of gross inland consumption in 2019, as compared to 28% in 2000. Similarly with oil, their use has diminished by just 3% between 2000 and 2019. Whereas in the case without Turkey, solid fuels' use has shrinked from 27% in 2000 to 21% in 2019. A logical sequence following EU's strong decarbonisation drive and the imposition of emission costs for coal and lignite power generation.But in the case of oil consumption, with the bulk of it used for transportation, and the lack of alternatives, the picture appears almost static. So, in the case of "with Turkey", oil use corresponded to 36% in 2000, which had dropped to only 33% in 2019. Whereas in the case of "without Turkey", the inertia with regard to oil use is even stronger since in 2000 oil consumption corresponded to 34% with this number remaining the same 20 years later.

When it comes to gas use despite the high hopes for this fuel over the years to provide a substitute to a large extent to solid fuels, this wishful thinking has not materialised. So, in the case "with Turkey", gas consumption in 2000, corresponded to 21%, having only risen to 22% by 2019. In the case of "without Turkey", which covers the entire Balkans peninsula, gas use from 22% in 2000 has dropped to 20% in 2019, clearly showing a determined stand by certain countries to avoid overexposure and reliance to a largely imported fuel. And although gas consumption per se has increased overall in SEE during the past 20 years, the dominance of solid fuels, supported by the rise of renewables, has meant that gas use as a percentage in the energy mix has maintained a steady position.

It should be noticed, that the total gross energy consumption in the region from 222.7 Mtoe in 2000 has been increased to 251,2 Mtoe in 2009 and 300.6 Mtoe in 2019. With Renewable Energy Sources (RES) we have a far more dynamic situation in the case of both "with" and "without Turkey". In 2000, the portion of RES corresponded to 10% and 9% respectively for the "with Turkey" and "without" options, with inputs mainly contributed by large hydro power stations and biomass and very limited geothermal, wind and solar geothermal,. Fast forward to 2019 and the situation has dramatically changed as in both cases we note a significant increase. In the case "with Turkey", RES input rises to 16% in 2019 from 10% in 2000 whereas in the case "without Turkey" the change is even more profound as the RES share has risen from 9% in 2000 to 16% in 2019.

Nuclear power maintains its share unchanged at 8% over the 20-year period in the case of "without Turkey". Whereas in the case "with

Turkey", nuclear's share becomes smaller from 5% in 2000 to 4% in 2019. This can be explained from Turkey's huge inputs from solid fuels, gas and RES which have substantially increased over the 20-year period. Finally, we have the 1% input from electricity for both cases (with and without Turkey) which means that the region has become a net electricity importer. A change of status, compared to twenty years ago, when the countries of the region were either self-sufficient in electricity or even net exporters as was the case of West Balkans, Romania and Bulgaria.

Sources: Eurostat, IENE

Looking at the broad energy picture of the region (with and without Turkey), one can see that solid fuels, which include coal and lignite, maintain their strong position, despite the fact that their share decreased at 24% in 2019, compared to 27% in 2009 in the case of 'with Turkey'. Likewise, oil's share remained strong and stable at 33% in 2019, compared to 2009. Solid fuels' and oil's dominance as well as the inherent difficulties in decarbonizing the region are discussed in detail in the relevant Chapters of the present study (see Chapters 3, 4, 9.2 and 10).

The role of natural gas is also important, the share of which in the case that Turkey is included in our calculations, remained almost the same at 22% in 2019, compared to 23% in 2009. This is understandable if we consider regional developments during 2009-2019, where natural gas did not made significant inroads in the West Balkans as they remained largely without gas infrastructure, while gas use in Bulgaria and Romania did not increase substantially. It is only last year (2020), where the operation of new gas infrastructure projects, such as Krk FSRU in Croatia, the Turk Stream and the TANAP-TAP system, provided more gas quantities to the region.

But the real reason for gas stagnation in SEE is that solid fuels have retained their strong position together with rising inputs from RES. If we are to exclude Turkey, where gas use subsided over the last 2-3 years, we see slightly higher gas use as decarbonization takes hold in Greece and Romania.

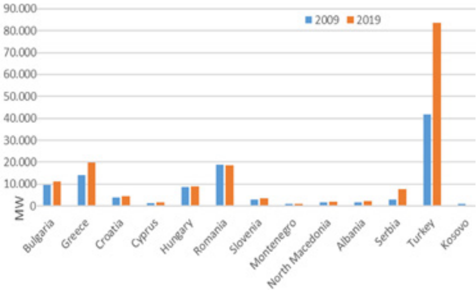
In addition, nuclear's share for power generation, including Turkey, remained small (at 5%) in 2019, compared to 2009, as no new nuclear capacity has come on stream, while the share of renewables increased considerably during this period, making significant impact in power generation. This is of course set to change over the next decade with the entry of nuclear power in Turkey and expansion of its use in Romania and possibly in Bulgaria while Serbia recently (2021) announced its interest for the installation of a nuclear plant.

A common feature of SE Europe (with the exception of Greece and Turkey) is that key elements of the region's energy infrastructures (e.g. gas pipelines, major thermal power plants) were built in the 1960s and 1970s, based on standard Soviet era technology. This concentration in age and type of technology often, combined with poor maintenance, creates serious challenges in terms of infrastructure upgrades, especially now where there is an urgent need towards decarbonisation, meaning the replacement of ageing infrastructure and the abandonment of lignite-fired power plants.

Almost all countries (with the exception of Albania, Romania and Croatia) depend heavily on hydrocarbon imports, from outside the region. Shared infrastructure also creates a high level of interdependence within the region itself. For instance, all countries participate in extensive daily and seasonal exchanges of electricity, while Serbian oil refineries rely on deliveries through the Croatian pipeline network and North Macedonia imports all its crude via pipeline from Greece. An analysis of the data reveals the region's huge dependence on oil and gas imports (see Fig 1.6). The region was 87% dependent on outside oil supplies in 2019, a situation which was even worse in the case of natural gas where import dependence exceeded 88%. With consumption set to increase over the coming years, the energy supply situation is bound to worsen at a time when the international situation in terms of security of supply tends to become more uncertain.

The electricity sector and its further expansion constitute the backbone for the region's economic and energy development. With about 165 GW of total installed electricity capacity in 2019, the impression is given that the region's electricity system is more than adequately supplied. However, this is not absolutely true as important disparities exist between the various countries' installed capacity, as can be clearly seen in Figure 1.13. It should be pointed out that the total power generation in the region from 486.1TWh in 2009 has been increased to 581.8TWh in 2019.

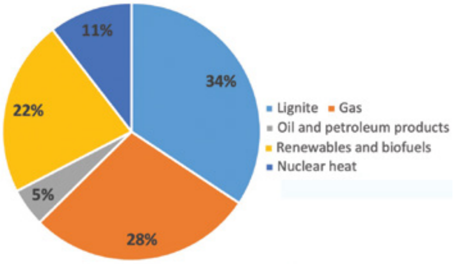
Figure 1.13 **Total Electricity Installed Capacity in SE Europe (2009 and 2019)**



Sources: Eurostat, IENE

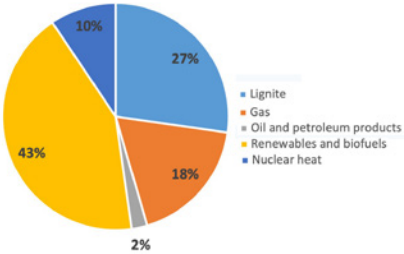
On the other hand, the region's electricity mix, which is shown in Figures 1.14 and 1.15 for 2009 and 2019 respectively, is not adequately diversified, as large thermal plants, mostly coal, lignite and gas fired, provide the bulk of power generation. However, the situation is different at national level as the prime fuel for power generation varies considerably from country to country. In the West Balkans, hydroelectricity as well as coal/lignite form the basis for power generation, with Albania relying almost 100% on hydro, while Kosovo depends 100% on lignite and the other countries enjoy a mix based on oil, gas and renewables. On the other hand, in the East Balkans, the energy mix for power generation is a lot more diversified, with the addition of nuclear energy and the wider use of natural gas, which is the case in Bulgaria and Romania, whereas Greece and Turkey rely heavily on lignite and thermal coal, but with growing inputs from renewables, including wind, solar photovoltaic and hydro and soon nuclear in the case of Turkey.

Figure 1.14 **Power Generation Mix in SE Europe, including Turkey, 2009 (Total=39.6 Mtoe)**



Sources: Eurostat, IENE

Figure 1.15 **Power Generation Mix in SE Europe, including Turkey, 2019 (Total=45.5 Mtoe)**



Sources: Eurostat, IENE

Since the early 2000, electricity transmission system operators (TSOs) in the region have focused on two priority areas: (a) the rehabilitation of grids and interconnections in the area of Western Balkans, and (b) the building of new interconnections in order to handle even more demanding electricity flows between the various countries as witnessed by latest developments throughout the region.

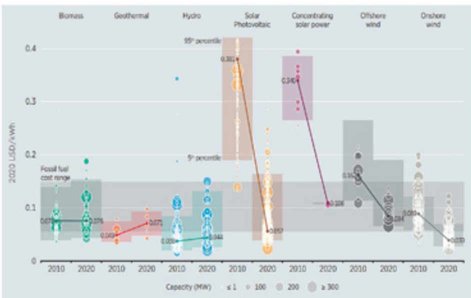
Both were and will be necessary over the next few years, but one important challenge that should be taken into consideration is the decrease in the cost of electricity grids, which is difficult as the soil morphology is different on a country-by-country analysis. The same also stands for renewables.

A substantial fall in the cost of renewables (CAPEX and OPEX) has been recorded over the last decade and thus, renewables are becoming more and more competitive in the energy landscape. More specifically, based on IRENA's data[11], the decade between 2010 and 2020 saw dramatic improvement in the competitiveness of solar and wind power technologies, as the cost of electricity from utility-scale solar photovoltaics decreased by 85%, followed by concentrating solar power or CSP (68%), onshore wind (56%) and offshore wind (48%), as shown in Figure 1.16.

[11] IRENA (2021), "Renewable Power Generation Costs in 2020", https://www.irena.org/publications/2021/Jun/Renewable-Power-Costs-in-2020

The last decade has seen CSP, offshore wind and utility-scale solar PV all join onshore wind in the cost range for new capacity fired by fossil fuels, when calculated without the benefit of financial support. Indeed, the trend is not only one of renewables competing with fossil fuels, but significantly undercutting them.

Figure 1.16 **Global LCOEs from Newly Commissioned, Utility-Scale Renewable Power Generation Technologies, 2010-2020**



Source: IRENA Renewable Cost Database

Note: This data is for the year of commissioning. The diameter of the circle represents the size of the project, with its centre the value for the cost of each project on the Y-axis. The thick lines are the global weighted-average LCOE values for plants commissioned in each year. Real WACC was 7.5% in 2010 and 5% in 2020 for OECD countries and China, and 10% in 2010 and 7.5% in 2020 for the rest of the world. The single band represents the fossil-fuel fired power generation cost range, while the bands for each technology and year represent the 5th and 95th percentile bands for renewable projects.

Source: IRENA

This development has a positive impact on the acceptability of renewables. Cheap renewables mean that more of them can be used; thus, facilitating global energy transition process and satisfying the new "Fit for 55" package as well as the Glasgow Climate Pact in the aftermath of COP26. However, the world is still a long way from producing all of its required electricity from renewables, as these sources, especially wind and solar, are intermittent and energy storage technologies have not been adequately developed.

Overall, examining the energy situation at regional level, we can see those changes in the energy sector, are mainly driven by energy transition considerations in the EU country block and by energy security in the rest, including Turkey Israel and West Balkans. Moreover, these changes are taking place at widely differing speeds and on the basis of diverse criteria. A situation likely to change over the next decade as energy transition priorities are expected to take hold and provide the single most important energy policy driving force.

Regional Economic Outlook

Regional Economic Outlook

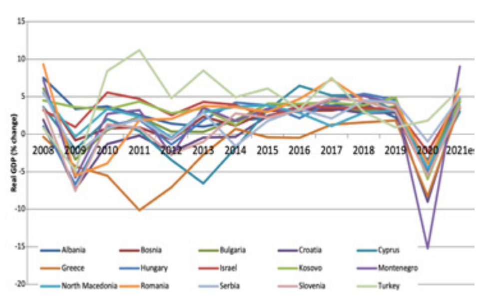
Introduction

Energy demand, by and large, is steadily correlated to economic development and growth and hence an understanding of the region's economy as a whole and on the basis of the countries included in the present "Outlook" report is of paramount importance.

Although the economies of the SE European region appear widely divergent in terms of structure and levels of development, they share a number of challenges which appear to be common to all. Among these, the global economic and financial crisis, which started in 2008, but affected all countries for many years after, and lately the coronavirus pandemic, which took hold in 2020 and still persists, have deeply affected the region collectively and each country individually. In this Chapter, we highlight the region's economic development challenges and also examine the key economic problems facing the various countries, especially taking into consideration the emerging post-pandemic climate.

At times when economic analysts employ various techniques to speculate about what the future might hold, the sobering reality is that these techniques become ineffective when the human factor is ignored. It is our view that only states whose governments possess the political determination to cease managing the economy through outdated inflexible state control mechanisms will eventually thrive. This is not to deny the necessity for state intervention when needs arise (e.g. disruption of supplies, market dysfunctions), but continuous state control cannot be the norm.This is especially relevant to the energy sector which forms a key part of the economies of most countries in SE Europe and which, as it is clearly seen in the present study, is in the process of rapid transition. As energy markets in the region (i.e. gas and electricity) move towards full liberalization, while at the same time addressing a massive influx of carbon free energy sources through open market competition, they come face to face with the remnants of monolithic state control attitudes still prevalent in several countries, some of them EU member states. It is therefore hardly surprising that achieving high rates of economic growth is not an obvious priority for many SE European countries and this certainly affects to a large extent the energy/power sector. A problem facing the SEE region is that it is not homogeneous since it includes economies of different speed and structure, such as those of EU member states (i.e. Bulgaria, Croatia, Cyprus, Greece, Romania, Hungary and Slovenia), the post-Communist Western Balkan Six (WB6) countries, which are non-EU members, but they are aspiring to become members one day, and Turkey and Israel. The key challenge for the WB6 countries is at one point to achieve European economic standards and hence, to enhance their economic growth. Therefore, in the WB6 countries, the enhancement of economic growth rates must be a result of properly planned and carefully implemented market-oriented reforms. Israel and Turkey have a combination of economic, energy and political interests that affect their economic relations, which in turn are being affected in terms of energy from all the SE European countries.The 2008 global crisis affected almost all macroeconomic variables: production, consumption, investment, unemployment and exports, while the coronavirus pandemic, still underway, had almost the same type of repercussions, albeit with a much deeper GDP slump and a different time frame (see Figure 2.1).

Figure 2.1 **Real GDP Growth (% Change y-o-y) in SE Europe, 2008-2021e**



Source: IMF World Economic Outlook (April 2021)

2.1 The European Economy and the SEE EU Member States

When discussing the regional, macroeconomic outlook, one should be aware that the SEE region is characterized by a strong variation in the structure, maturity and perspective of its respective economies. One could make a distinction among 4 groups of countries, in order to obtain a more coherent view over the development process of each country. The four groups could be summarized as follows:

(1) Greece, Cyprus and Slovenia > old EU members and part of the Eurozone (already discussed)
(2) Bulgaria, Romania, Hungary and Croatia > latest EU member states, which do not belong to the Eurozone group (already discussed)
(3) Serbia, North Macedonia, Montenegro, Bosnia and Herzegovina, Albania and Kosovo > the Western Balkan economies, EU candidates
(4) Turkey and Israel > East Med countries, with dynamic and internationally oriented economies, enjoying preferential economic relations with the EU

Even if this classification appears arbitrary on scientific or econometric terms, following references to historical and institutional resemblance, this grouping is more pragmatic as one can obtain useful insights over the development path of each country.Although the economies of the Western Balkan Six countries, together with those of Turkey and Israel, are discussed under separate sections (i.e. 2.2. and 2.3.), their economies are to a large extent influenced by economic conditions in the eurozone and in the EU Member States in SE Europe.

2.1.1 The European Economy

The near-term outlook for the European economy looks weaker than the one anticipated in the autumn of 2020, as the coronavirus pandemic has tightened its grip on the continent. The resurgence in infections since the start of 2021, together with the appearance of new, more contagious variants of the coronavirus, have forced many EU member states to reintroduce or tighten containment measures. The European economy has thus ended 2020 and started the new year on a much weaker footing. However, light is now appearing at the end of the tunnel. As vaccination campaigns gain momentum and the pressure on health systems to subside, containment measures are set to relax gradually. This is expected to have a positive impact on economic outlook for H2 2021.

The breakthrough development of vaccines in the autumn and the start of mass vaccination campaigns brightened the outlook beyond the near term. Furthermore, the agreement reached between the European Union and the United Kingdom (January 2021) on the terms of their future cooperation reduced the cost of the UK's departure from the Single Market and Customs Union, while endorsement of the Recovery and Resilience Facility is set to support EU member states on their way to a sustainable recovery.

Overall, GDP is now forecast to grow by 3.7% in 2021 and 3.9% in 2022 in the EU, and by 3.8% in both years in the euro area. It is now expected that the EU economy could reach the pre-crisis level of output earlier than anticipated back in the European Commission's Autumn (2020) Forecast, largely because of the stronger momentum in the second half of 2021 and in 2022. The speed of the recovery will, however, vary significantly across the EU. Some countries have suffered more during the pandemic than others, whereas some are more dependent on sectors such as tourism, which are likely to remain weak for some time. As a result, while some EU member states are expected to see economic output return to their pre-pandemic levels by the end of 2021 or early 2022, others are forecast to take longer.
Inflation in the euro area and the EU is expected to be slightly higher in 2021 compared to last autumn, but to remain subdued despite a temporary boost from base effects. In the euro area, inflation is forecast to increase from 0.3% in 2020 to 1.4% in 2021 before moderating slightly to 1.3% in 2022.

These projections are subject to significant uncertainty and elevated risks, predominately linked to the evolution of the pandemic and the success of vaccination campaigns.

On the positive side, the vaccination process could lead to a faster easing of containment measures and therefore an earlier and stronger recovery. Moreover, the strength of the rebound could surprise on the upside driven by a burst of post-crisis optimism that would unleash stronger pent-up demand and innovative investment projects, thanks to historically high household savings, low financing costs, and supportive policies. On the negative side, the pandemic could prove more persistent or turn out more severe in the near term, pushing back the expected recovery. There is also a risk of deeper scars in the fabric of the European economy and society inflicted by the protracted crisis, through bankruptcies, long-term unemployment, and higher inequalities. The uncertainties around the forecast are illustrated by the scenario analysis presenting alternative paths for the European economy under different sets of assumptions. Last, but not least, an ambitious and swift implementation of the NextGenerationEU programme, including its Recovery and Resilience Facility, should provide a strong boost to the EU economy.

Table 2. 1 **Overview of the EU's Winter 2021 Interim Forecast**

Real GDP Growth	Winter 2021 Interim Forecast 2020	2021	2022	Autumn 2020 Forecast 2020	2021	2022

Source: European Commission

2.1.2 The SEE EU Member States

The EU member states in SE Europe include seven countries, i.e. Greece, Cyprus, Slovenia, Bulgaria, Croatia, Hungary and Romania. For comparison purposes, estimates for 2021 and 2022 from both the European Commission and IMF will be provided, while a country-by-country analysis of the economies follows.

Greece

Based on Eurostat's data, Greece's GDP increased by 2.3% q-o-q during the third quarter of 2020, reflecting the reopening of the economy and the temporary easing of the containment measures at that time. The recovery in the third quarter was mainly driven by domestic demand. Economic activity in the services sector decreased sharply due to the negative impact of the COVID-19 pandemic on tourism, while construction showed some resilience. Following the re-introduction of containment measures during the fourth quarter of 2020, output growth is forecast to turn negative in quarterly terms. Overall, Greece's real GDP is expected to have declined by 10% in 2020, based on Eurostat's estimates. Containment measures are expected to weigh on Greece's recovery, with real GDP expected to grow by 3.5% in 2021, before rising to 5% in 2022, based on Eurostat's estimates. The recovery will continue to be supported mainly by private consumption, on the back of the gradual reopening of retail trade, improving consumer confidence and the supportive setting of fiscal policy in the economy. Net exports are expected to contribute positively to growth in 2021 and 2022, with the rollout of vaccination campaigns expected to support only a gradual return of tourists to Greece. Investment is forecast to recover as well but at a slower pace. The support measures adopted by the authorities have bolstered credit growth to businesses.

Unemployment stood at 16.7% in October 2020, similar to a year before, indicating that the labour market impact of the economic crisis remains relatively contained. Employment, however, decreased, primarily due to lower hirings in the tourist sector. After dropping by 1.3% in 2020, inflation is forecast to remain mildly negative in 2021 before turning positive in 2022. The negative growth in prices is mainly driven by an expected drop in service sector prices.

Table 2. 2 **Macroeconomic Performance of Greece**

Greece	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021e

Source: IMF World Economic Outlook (April 2021)

The forecast remains subject to large uncertainty. The developments regarding the global health crisis and the vaccination rollout will be crucial for the recovery of the tourism sector and the speed of recovery in the private sector after the expiry of government support measures. In addition to that, geopolitical tensions in the region and the migration crisis add further uncertainty to the forecast. On the upside, the European Commission's forecast does not incorporate the impact of the Recovery and Resilience Plan, which could provide a significant boost to domestic demand once implemented.

Cyprus

Based on Eurostat's data, Cyprus's real GDP rebounded strongly in the third quarter of 2020 (+9.4%, compared to the second quarter). This rebound was driven by domestic demand, which was mainly underpinned by fiscal stimulus, while exports of goods and services decreased. The recovery lost some steam towards the end of the year as lockdown measures were reintroduced to combat a resurgence in COVID-19 infections. Economic sentiment and consumer confidence worsened in the last two months of the year and again in January 2021. Based on Eurostat's estimates, Cyprus's real GDP is estimated to have contracted by 5.8% in 2020.

In 2021, a partial recovery is forecast, with real GDP growth expected to reach 3.2%. Containment measures have become stricter since the start of the year but they affect a smaller share of economic activity than in spring 2020. As restrictions are expected to continue until vaccinations pick up and cases drop, the recovery is expected to take place mainly in the second half of 2021. Domestic demand is again expected to be the main contributor to growth. Policy measures adopted to mitigate the impact of the crisis have been extended into 2021, and some of them, such as the loan repayment moratorium, are planned to remain in place at least until June 2021.

These measures should continue to support employment, household incomes and help businesses to maintain their capacity. Furthermore, construction activity has so far escaped disruption from the lockdown measures. Tourism, a key sector for Cyprus, has borne the brunt of the COVID-19 pandemic. Receipts from tourism have significantly declined by around 85% in 2020. This trend is expected to be only partially reversed in 2021. On the supply side, interruptions to airline capacity and, on the demand side, varying progress with vaccinations in Cyprus's main tourist markets and lower confidence in air travel are expected to weigh on the sector's recovery. In 2022, real GDP is forecast to grow by 3.1% and return to its 2019 level, based on Eurostat's estimates. This will be mainly on the back of domestic demand, as well as a small positive contribution from net exports. Future spending related to the Recovery and Resilience Facility is not included in the European Commission's forecast and constitutes an upside risk.

Cyprus's inflation fell to -1.1% in 2020, dragged down by lower prices for energy and processed foods. In addition, the VAT rate reduction in the hospitality industry led to a fall in the prices of services. Inflation is forecast to turn positive again in 2021 and 2022, at 0.7% and 1.1%, respectively, underpinned by higher energy and services prices.

Slovenia

Based on Eurostat's data, Slovenia's GDP is estimated to have contracted by 6.2% in 2020. Over the first three quarters, private consumption was 8.4% and investment 6.5% lower than in the same period in 2019. Imports fell more than exports, leading to a positive contribution from net exports. The recovery in the third quarter of last year, however, was followed by a strong resurgence in COVID-19 infections and the introduction of new restrictions in the fourth quarter that dampened economic sentiment and reduced private consumption significantly. The impact of the crisis was softened by extensive government measures to support employment and limit insolvencies. Still, employment decreased and the unemployment rate increased slightly.

The pandemic and its associated restrictions continue to exert a strong influence over the economy in early 2021, particularly in the services sector. Industrial production and construction are expected to be less affected. The economic situation is expected to gradually improve as more people are vaccinated and restrictions are relaxed, leading to stronger growth in the second half of the year.

Overall, GDP is forecast to grow by 4.7% in 2021, based on Eurostat's estimates, supported by both strong domestic demand and positive net exports. Thereafter, the economy is expected to grow by 5.2% in 2022, driven by the same factors as in 2021. GDP is expected to exceed its end-2019 level by the end of 2022.

Once support measures end, the recent increase in the minimum wage could place additional strain on struggling companies in the services sector. This constitutes a downside risk to the forecast. The forecast factors in some of the measures expected to be funded under the Recovery and Resilience Facility representing about 0.6% of GDP. Higher use of the facility is an upside risk. The sharp decline in oil prices in March 2020 led to deflationary pressures that were still being felt at the end of 2020 despite the partial recovery in energy prices.

Overall, energy prices decreased by 0.3% in 2020. Inflation is expected to remain very low in the beginning of 2021 and to increase somewhat in the second half of the year. Overall, prices are expected to increase by 0.8% in 2021. In 2022, taking into account the projected recovery and assumed increase in energy prices, inflation is expected to reach 1.7%.

Bulgaria

Based on Eurostat's data, Bulgaria's economic activity declined markedly in 2020 due to the COVID-19 pandemic. Private consumption dynamics followed the introduction and subsequent relaxation of containment measures. In late November 2020, a second wave of the pandemic led to the re-introduction of containment measures which are still in place and which continue to weigh on household consumption and business sentiment in trade and the services sector. Private investment remained depressed throughout the first nine months of 2020, while public sector investment increased markedly in Q3 2020. Although exports within the EU have been recovering since mid-2020, sales to non-EU countries have continued to falter. The COVID-19 pandemic has led to a significant loss in revenues from foreign tourists, which typically account for around three quarters of revenues from tourist accommodation. Overall, Bulgaria's real GDP is expected to fell by 4.9% in 2020, based on Eurostat's estimates.

Looking forward, domestic demand is forecast to remain subdued in the first half of 2021, given the assumed extension of containment measures. The eventual re-opening of the economy should provide a boost to consumption and investment in the second half of 2021. Goods exports are expected to gradually recover from the second quarter onwards, while foreign tourists are expected to start returning in the third quarter. The recovery in foreign tourism, however, is subject to a downside risk linked to the relative rates of vaccination and contagion in Bulgaria compared to alternative tourist destinations. Against this backdrop, real GDP growth is forecast to reach 2.7% in 2021, before accelerating to 4.9% in 2022 on the back of strong domestic demand and more buoyant exports. As the European Commission's forecast does not take into account the implementation of the Recovery and Resilience Plan, an upside risk to public investment emerges.

Annual average inflation fell to 1.2% in 2020 due to falling energy prices and abating price dynamics in services and unprocessed foods. Inflation is set to increase to 1.7% in 2021 and 1.8% in 2022, driven by price increases in processed foods and services.

Croatia

Based on Eurostat's data, Croatia's economy is estimated to have contracted by 8.9% in 2020. This sharp decline is mainly attributable to the impact of the COVID-19 pandemic on service exports, particularly tourism, which suffered greatly due to the fall in demand for air travel and the imposition of travel restrictions in many countries. Private consumption also fell, reflecting the accumulation of involuntary and precautionary savings. Following a better-than-expected third quarter, GDP is estimated to have contracted again towards the end of the year as pandemic suppression measures were reintroduced in December.

Based on Eurostat's estimates, Croatia's real GDP is forecast to bounce back by 5.3% in 2021, as domestic demand should rebound once pandemic containment measures are phased out and more people are vaccinated. Pent-up demand[1], coupled with a gradual recovery in the labour market, is expected to boost private consumption. Investment should rebound on the back of the already strong dynamics in the construction sector, supported by rebuilding efforts following the strong earthquakes in the Banija region and Zagreb in December 2020. A gradual pick up in longer-term investment projects, is also expected. The recovery in external demand, however, is expected to be uneven. Goods exports are expected to increase strongly on the back of the improved global outlook but services exports are projected to remain subdued in both 2021 and 2022 compared to their 2019 levels. This is mainly because the recovery in the travel and hospitality sectors is likely to take several years. The European Commission's forecast does not include any measures expected to be funded under the Recovery and Resilience Facility, posing an upside risk to the growth projections.

Based on Eurostat's data, Croatia's inflation rate dropped to 0% in 2020 on the back of a strong decline in energy prices, while core inflation remained broadly stable at around 1%.

As the effect of last year's fall in oil prices dissipates, inflation is expected to pick up slightly in 2021 but should remain subdued throughout the forecast horizon (1.2% in 2021 and 1.5% in 2022).

Table 2. 6 **Macroeconomic Performance of Croatia**

Hungary

Based on Eurostat's data, Hungary's economy bounced back by 11.4% q-o-q in the third quarter of 2020, after the first pandemic related lockdown ended. Industry, construction and retail sales remained strong in October and November. However, the rebound was interrupted by a second wave of the pandemic, which led to another round of restrictions from mid-November that mainly affected the hospitality, leisure and entertainment sectors. As a consequence, GDP is expected to have decreased slightly in the fourth quarter of 2020, based on Eurostat's estimates. Overall, Hungary's GDP is expected to show a 5.3% contraction in 2020, mostly driven by plummeting investment and service exports.

Consumption is also likely to show a decrease given the fall in household income and confidence and the limited opportunities to consume certain services during the lockdown. The current containment measures will start to be eased only once case numbers drop substantially or vaccines become widely available, thus they will remain a drag on GDP growth in the near-term. In addition, the manufacturing sector faces supply chain disruptions, which could hinder production in the short-term. The assumed easing of public health measures should set the stage for a quick rebound in economic activity from mid-2021.

Based on Eurostat's estimates, Hungary's real GDP is forecast to grow by 4% in 2021 and by 5% in 2022, supported by all final demand components. There are upside risks to the European Commission's forecast as the baseline projection does not include any measures funded by the Recovery and Resilience Facility.

The unemployment rate stood at 4.3% in December 2020, almost unchanged compared to previous months. However, an increasing share of employees reported zero working hours and household unemployment expectations also rose. The government has provided some support to preserve employment in the sectors most affected by the second lockdown, which is mitigating its negative economic impact. Job creation is expected to resume after the economy returns to growth, but lingering labour market slack is likely to temper wage growth.

Inflation eased in the last months of 2020 as food and fuel prices decreased. The country's inflation was at 3.4% in 2020 and it is projected to remain at 3.5% in 2021, based on Eurostat's estimates, due to the pass-through of earlier currency depreciation and rising excise duties on tobacco. After these temporary factors fade, inflation is expected to ease to 2.9% on the back of the subdued growth of unit labour costs.

Romania

After a 12.2% contraction in the second quarter of last year, Romania's economy rebounded by 5.8% in Q3 2020, based on Eurostat's data, mainly due to a recovery in private consumption. The strong performance of the construction sector sustained gross fixed capital formation growth throughout the year. Meanwhile, net exports continued to contribute negatively to growth in 2020 despite exports recovering somewhat faster than imports in the third quarter. Industrial production made up for some of its earlier losses in the second and third quarter of 2020, but this positive performance appeared to stall in the beginning of the last quarter.

Economic activity is expected to have weakened somewhat in Q4 2020 as pandemic containment restrictions were reintroduced in response to a new wave of infections. Fiscal support measures, some of which have been extended until mid-2021, mitigated the impact of the crisis on the economy in 2020. The unemployment rate remained around 5%, as government policy measures cushioned the blow to the labour market.

Table 2. 8 **Macroeconomic Performance of Romania**

Source: IMF World Economic Outlook (April 2021)

Based on Eurostat's estimates, Romania's real GDP is forecast to grow by 3.8% in 2021 and by 4% in 2022. Private consumption is expected to recover strongly from the second half of 2021 as the rollout of vaccinations should allow for a gradual lifting of restrictions. Consumption is expected to remain robust in 2022. Investment is set to remain strong over the forecast horizon, supported by the construction sector. Exports are expected to recover against the backdrop of improved economic conditions in Romania's main trading partners. However, the contribution of net exports to growth is expected to remain negative over the forecast horizon.Future spending related to the Recovery and Resilience Facility is not included in this European Commission's forecast.

Risks to the growth forecast are tilted to the upside. Particular upside risks for Romania are a fast implementation of the Recovery and Resilience Plan and an improvement of public finances.

In 2020, a sharp drop in energy prices and subdued aggregate demand pushed headline inflation down to 2.3% from 3.9% in 2019. In 2021, some inflationary pressures are expected to come from higher oil prices and the liberalisation of the retail electricity market on 1 January, which is set to increase energy prices in the first part of the year. The annual average rate of inflation is forecast to slightly increase to 2.6% in 2021 and to decline somewhat to 2.4 % in 2022.

2.2 The Western Balkan Economies: Serbia, North Macedonia, Montenegro, Bosnia and Herzegovina, Albania and Kosovo

The third group of countries constitutes the so called "weak link" of the SE European economies. Historically divergent and financially vulnerable, they all aspire to join at some point the EU, while trying to surpass their bilateral conflicting past. The main challenges the six countries have to deal with are the existence of a macroeconomic stability necessary for sustained income growth, competitiveness, strong labor market and public finances in order to restart their EU convergence process that was postponed since the 2008 global financial and economic crisis. The adoption of structural reforms should be multidimensional: investment support through the business environment improvement, deepen global integration, more efficient public services, etc. Another important aspect is the challenge of rising transit migration through the region and how the EU and the corresponding governments will handle this, as this could disrupt regional trade, labor markets and remittances.

Serbia

After a robust growth of 4.2% in 2019, the COVID-19 pandemic caused a recession of 1% in 2020. This is a significantly better result than what was previously projected (a drop of 3%). Services' sectors were hit most by the pandemic-related events (down 1.5% y-o-y), while value added in industry remained flat in real terms, and the agriculture sector grew by 4.9%. On the expenditure side, both investment and consumption had a negative contribution to growth in 2020 (-1.1% and -0.7%, respectively), while net exports had a positive contribution to growth (0.8%).

A large fiscal stimulus program, introduced by the government, close to 13% of GDP helped keep the recession mild. It comprised tax deferrals and increased expenditures of around 8% of GDP and guarantees in the amount of 4.8% of GDP. As the largest part of the package (7.4% of GDP) went to businesses, it helped to avoid a major loss in employment. In fact, registered employment increased by 1.9% compared to 2019. The Q3 unemployment rate, as measured by the Labor Force Survey, stood at 9% in 2020, slightly lower than 2019. The wage subsidy and cash support to citizens also helped avert a spike in poverty, although at a significant fiscal cost. Due to the support package, limited labor market impacts, and growth in agriculture, poverty (income under $5.5/day in revised 2011 PPP) is estimated to have remained stagnant from 17.3% in 2019 to 17.4% in 2020.

The fiscal deficit increased significantly in 2020 and reached an estimated 8.1% of GDP. This increase is primarily the result of the large fiscal stimulus program. Public debt is estimated at 58.2% of GDP by end-2020. Inflation by year-end reached 1.3% y-o-y; however, food prices increased by 2.1%. The dinar remained broadly stable against the euro, supported by significant interventions by the National Bank of Serbia (NBS) on the foreign exchange market (NBS sold reserves worth €1.5 billion in 2020). The banking sector's performance remains robust despite two rounds of debt moratoria introduced in 2020 as part of the COVID-19 response measures. Non-Performing Loans (NPLs) stood at 3.5% as of November 2020. On the external side, the CAD decreased significantly – from 6.9% of GDP in 2019 to 4.3% in 2020.

Recovery from the COVID-19 related recession is expected to start in 2021. Growth will be supported by a recently announced new package of measures to support citizens and the economy worth 5.1% of GDP. As a result, Serbia's economy is expected to rebound by 5% in 2021, based on the World Bank's estimates. Over the medium term, growth is expected to be around 4%. Growth will be driven by consumption and investment will recover only slowly, which may slow down the impact of growth on labor markets (both employment and wages). This medium-term outlook crucially depends on international developments (including the control of COVID-19), the pace of structural reforms and political developments.

Source: IMF World Economic Outlook (April 2021)

Immediate focus is needed on measures to improve the business environment and governance in order to lower the cost of doing business and ensure security and safety, as well as efforts to improve the quality of infrastructure. Regarding the medium- to long-term challenges the focus should be on demography and climate change. Firstly, an aging and shrinking population will leave Serbia with a smaller available labor force. Labor shortages combined with skills mismatches could significantly hurt the competitiveness of the Serbian economy. Secondly, the impact of climate change – including more frequent and severe droughts and floods – will hit agriculture and food production hard and will make the cost of infrastructure maintenance much higher.

The pace of labor market recovery will be critical for resumed poverty reduction. The new package is expected to support citizens and economic recovery, though poor and vulnerable households, who tend to depend more on self-employment and less secure jobs, may take longer to regain their income level. Poverty is projected to slowly decline to 16.8% in 2021.

In the medium term, regional disputes and slow progress with the EU accession process could affect investment sentiment and therefore delay investment projects in infrastructure and other sectors. Labor market challenges limit the scope for robust welfare improvements and could be exacerbated by a significant brain-drain.

North Macedonia

According to the World Bank, North Macedonia's real GDP declined by 4.5% in 2020; less than earlier projected as the recession sharply eased in Q4 2020. Private consumption, the main driver of growth in the past, experienced a sharp decline of 5.6% y-o-y as a result of containment measures. Investment also declined by more than 10%, even though it shortly rebounded in Q3 2020. Government induced consumption that increased by almost 10% helped partly alleviate declining domestic demand. External demand also plummeted, reflected in a 10.9% y-o-y decline of exports. The accompanying decline in imports alleviated the pressure on the current account deficit which is expected to remain largely unchanged compared to 2019. On the production side, agriculture, ICT and real estate activities were only sectors growing in 2020.

Government support helped cushion the crisis impact on the labor market by supporting over 130,000 jobs through wage subsidies in April 2020, declining to 60,000 towards the year-end as the economy slowly recovered. The unemployment rate remained largely unchanged, but this was partly a result of people dropping out of the labor market. The banking sector liquidity ratio of over 23% in Q3 2020 remained adequate, helped by the central bank measures. Credit continued growing at 4.7% y-o-y by end-2020, on account of both household and firm credits supported by strong deposit growth and crisis-support programs.

Non-performing loans declined to 3.3%, given the allowed suspension on credit reclassification requirements until December. However, an upward correction is expected in 2021 as this measure ended. The capital adequacy ratio stood at 16.9% in Q3 2020, double the mandatory level. Inflation remained low at 1.2% y-o-y in 2020, reflecting subdued output and despite rising food prices in the second half of 2020. The fiscal deficit tripled to 8.9% of GDP in 2020. The drop in VAT and excise revenues amounted to 0.9% of GDP and was cushioned somewhat by an increase in social contributions. Spending increased by 4.4% of GDP, as health expenditures and subsidy schemes, aimed at employment retention, surged. Spending on wages and pensions also increased as a result of previous policy changes, while capital spending declined. Public and publicly guaranteed debt increased to 60.2% of GDP as the government ramped up borrowing to finance the soaring deficit and repay maturing obligations.

Based on the World Bank's estimates, the economic growth is expected to rebound to 3.6% in 2021. This scenario assumes accelerated vaccinations by mid-2021, no further lockdowns, and increased external demand. In this scenario of a gradual recovery, after a protracted recession in Q1 2021, a rebound is expected thereafter, as restored consumer and investor confidence pushes up personal consumption, private investment, and exports. The fiscal deficit is planned at 4.9% but given the extended government support to firms and households in early 2021 of an additional 1.4% of GDP, the actual deficit will likely be higher.

Setting public finances back on a sustainable path will be needed over the medium term, as public and publicly guaranteed debt surpasses 64% of GDP in 2021. Targeting a primary balance over the medium term would be needed to stem further public debt growth and not crowd out productive spending. This is even more important in the eventuality that international financing costs rise. Boosting revenues through cutting back on exemptions and strengthening compliance are priorities along with a gradual state withdrawal from the corporate sector. Bringing people back to the labor market, as well as education and governance reforms could help boost potential growth. Poverty is projected to resume its decline as growth gradually recovers in 2021.

Montenegro

As a small, open, and heavily tourism-dependent economy, Montenegro was hit hard by COVID-19, affirming its vulnerabilities to strong boom-bust cycles. Over the five years prior to the crisis, economic growth averaged 4%, driven by large public investments and consumption. Over two-thirds of Montenegro's jobs are in services, which account for over 70% of value added. The external imbalances are structurally high and averaged 15% of GDP over 2015-2019, largely financed by net FDI and external debt. Due to weaker adherence to fiscal plans and debt-financed highway construction, public debt has doubled since independence. Montenegro aspires to join the EU, but significant rule of law challenges slow down progress and reflect a key development constraint. The crisis has wiped out recent economic and social gains from the period of strong growth and exacerbated Montenegro's vulnerabilities.These include: the lack of fiscal space, small production base and low diversification of the economy, business environment weaknesses, and income and social inequalities.

These vulnerabilities translate into significant reversals of progress in creating jobs, raising income, and reducing poverty. Montenegro ranks third in the number of infections per million inhabitants and records among the highest death rates per capita from COVID-19 in the world. The pace of recovery will depend on when the pandemic is contained and the pace of immunization, which is currently slow. In 2020, the new government committed to accelerating reforms, strengthening the rule of law, and fighting corruption. These, coupled with strong fiscal and debt management and independent and accountable state institutions, would enable more inclusive, private sector-led growth and efficient service delivery to citizens. In 2020, general government revenues declined by 13% y-o-y, strongly driven by declines in VAT (-24%). General government spending went up by 4.6%, partly due to support measures, while capital spending fell by 25%. In December, Montenegro placed a 7-year €750 million Eurobond, with an interest rate of 2.875% to pre-finance maturing debt and 2021 fiscal deficit, based on the World Bank's data.The financial sector was resilient in 2020: outstanding loans (including those in moratoria) were up by 3%, while deposits fell by 3%, driven by declining household deposits. Yet, new lending was down by 26% and bank profits declined by over 50%. As exports plunged and imports showed more resilience, the current account deficit widened to 26% of GDP.

The blurred outlook due to the pandemic developments and vaccine rollouts is further dimmed by lack of clarity on the government's medium-term plans. Due to a low base and assuming tourism recovers to 55% of 2019 levels, Montenegro's economy is expected to rebound in 2021 with an estimated GDP growth of 7.1%, based on the World Bank's estimates. The total output loss is, however, projected to be fully recovered only in 2023 when the economy is expected to grow 3.5%. External imbalances will remain elevated in 2021, but the finalization of the import-dependent motorway section and stronger exports led by the tourism recovery are projected to reduce the current account deficit to 13% and 10% of GDP in 2022 and 2023, respectively. After peaking at 105% of GDP in 2020, public debt is estimated to return to pre-crisis levels by 2023. However, the actual debt reduction trajectory might be steeper or flatter, depending on the government's medium-term budgetary plans which are still unknown, as it delayed the 2021 budget adoption. However, implementation of sound and credible fiscal policies is an imperative for debt sustainability.

The outlook on employment is also highly uncertain and depends on the recovery of labor-intensive sectors. The speed of recovery of low-skill jobs will partly determine how fast poor and vulnerable households can return to pre-crisis income levels. The poverty rate is projected to decline to 17.9% in 2021. The current crisis has made the longstanding policy priority of improving economic resilience more urgent than ever. In order to accelerate recovery and sustain inclusive growth and poverty reduction, "Montenegro must keep macroeconomic stability, ensure inclusive and efficient provision of public services, carefully manage its natural resources and strengthen the independence and capacities of its institutions", says the World Bank.

Bosnia and Herzegovina

Based on the World Bank's data, Bosnia's real GDP growth is projected at -4.0% in 2020 due to a slowdown in most productive sectors, a weaker external environment and high political uncertainty. In 2020, growth was positive in Q1 but after the introduction of a lockdown and containment measures in Q2, the economy faced a sudden stop as domestic and external demand dropped. By Q4 2020, the country's economic activity had somewhat improved, but growth remained in negative territory.

Unemployment has recently worsened. According to official estimates, the number of people in paid employment decreased approximately 1% y-o-y in November 2020, while the number of unemployed increased by about 3% in the same period. Deeper labour market effects have been prevented by wage subsidy programs in both entities and other policy measures targeting affected economic sectors aimed to safeguard potential job losses. As the economy has fallen into recession and with low oil prices deflation has returned. In December, the consumer price index was down 1.6% y-o-y. In 2020, a fiscal deficit of 5.5% of GDP is expected, down from a surplus of 1.9% in 2019. In 2020, revenues fell mainly due to the slump in tax revenue collection, while expenditures rose mainly as a result of higher spending on public wages, goods and services and social benefits. The current account deficit is estimated to have worsened slightly in 2020 due to a drop in the services balance and remittances. Total public debt, consisting largely of concessional debt, has increased and is estimated at 40.6% of GDP, while the total external debt is estimated at 72% of GDP.

Even during the pandemic, the financial sector has been broadly stable. On average, banks are sufficiently capitalized and liquid, but their profitability is eroding. The latest available poverty data using the national poverty line is for 2015 and the poverty rate was estimated at 16 percent, very close to the 15 percent estimated for 2011.The slowdown in the economy and the consequent loss of people's employment and earnings have negatively affected household welfare in 2020. Estimates show that many of those who may have been affected were not covered by social protection programs before the crisis. The outlook is marked by the implementation of measures to combat the pandemic. Authorities are currently focused on securing vaccines. As the pandemic subsides the Socio-Economic Program is expected to gain needed attention, mainly through the return of announced investments in energy and infrastructure. Consumption will continue to drive growth, resulting in strong growth of imports. Remittances will recover in the medium term and, together with progress on re-forms, will underpin a gradual pickup in consumption and finance a significant part of the trade deficit.

Source: IMF World Economic Outlook (April 2021)

Monetary policy anchored to the Euro will continue to support local currency stability. Safeguarding the banking sector will continue to be important in particular as the full impact of moratoria is yet to be assessed. Authorities have adopted budgets and secured funds to ensure necessary liquidity through credit lines via entity development banks to support affected businesses.

As Bosnia and Herzegovina does not have access to international markets, support from International Financial Institutions (IFIs) will be critical. As revenues recover Bosnia's fiscal deficit will return to surplus over the medium term. A stronger push on the capital investment program will need to remain a high priority for the authorities' economic programs.

Planned investments in energy, infrastructure, and tourism will also support job creation in those sectors after the crisis.

As the pandemic is tamed and the economy gradually recovers in 2021, improvements in labor market participation and employment will remain key for growth to translate into poverty reduction. There are several risks to the outlook but the main risk is a prolonged pandemic which could lead to lower growth rates in 2021 than projected. In addition, the challenging political environment will affect the implementation of the adopted socio-economic program. The main external risk for Bosnia and Herzegovina remains slow growth in the EU and political tensions in the region.

Albania

According to the World Bank, Albania's real GDP grew by 3.3% during 2015-2019, with the country achieving significant reform progress while aspiring to EU membership. A few large renewable energy projects and expansion in tourism and garments' manufacturing exports drove GDP and employment growth. However, productivity has stagnated below that of peer countries, and wage pressures could reduce competitiveness. Small and Medium Enterprises (SMEs) represent more than 90% of private firms and rely on low-skilled, low-wage labor. Limited access to finance, burdensome logistics and poor market integration discourage private investment, while scarce public revenues limit public infrastructure and human capital investment.

Growth halted in 2019, as a 6.4-magnitude earthquake with an epicentre 16 km west-southwest of Mamurras in November 2019 further exposed the country's low buffers. Fiscal consolidation was put on hold and external vulnerabilities reemerged. The pandemic hit Albania's key sectors of tourism and manufacturing through the recession in the EU, supply chain disruptions, travel limitations and social distancing measures.

Based on the World Bank's estimates, Albania's real GDP is projected to decline by 4.7% in 2020 due largely to a slowdown in tourism, though smaller than initially projected as domestic tourism demand partially compensated for the drop in foreign visits. Public support packages for reconstruction and to mitigate the crisis had a small estimated success in preventing an increase in poverty and had a significant fiscal cost. Recently, introduced tax incentives further stress already declining revenues. Delayed global vaccine rollout could cause long-lasting travel restrictions and could prevent a recovery of the country's services and manufacturing, worsening the performance of businesses and delaying the full recovery in employment. The normalization of the global economy will have a significant impact on the shape of the recovery.

Tourism and travel are likely to remain limited until global vaccination rollout is completed. In this scenario, Albania's real GDP is forecasted to grow by 4.4% in 2021, based on World Bank estimates, as exports, consumption and investment partially rebound. The services sector, led by tourism, and construction are expected to be key drivers of the recovery, in part thanks to reconstruction investment, following evidence from similar disasters in developing economies.

Poverty in Albania is expected to decline in line with anticipated recovery by about 2%. In the years following, private consumption will play an increasingly important role in growth, supported by reconstruction efforts. Private investment will contribute to growth, provided that the government continues to implement business climate reforms. Beyond 2021, government spending will likely be constrained by limited fiscal space. The fiscal situation could deteriorate in a downside growth scenario and in the absence of expanded revenue collection. In this case, the government may need to further reduce capital spending to keep the debt to GDP ratio from rising.

According to the World Bank, Albania's current account deficit is expected to narrow to 8.8% of GDP in 2021 and further decline to 6.5% in line with the pre-crisis trends, driven by projected improvements in the trade balance. Service exports, including tourism and fast-expanding business-process operations, should narrow the trade deficit over the medium term. Import growth will be high at 13% in 2021, as infrastructure investment speeds up.

With economic activity picking up, revenues are projected to recover to 27.6% of GDP by 2022-2025. Albania's public debt is projected to only marginally decrease to 79.5% of GDP in 2021. The employment outlook is largely dependent on the recovery of the services sectors and reconstruction, where jobs are mostly low pay and vulnerable to economic uncertainty.

Kosovo

Based on the World Bank's data, Kosovo's real GDP growth averaged 3.6% over 2009-2019 and, before the pandemic, was expected to exceed 4% in the medium term. Private investment added to growth in recent years, but was mostly concentrated in trade and construction industries, with limited productivity spillovers.

Likewise, robust growth did not translate into more jobs as the employment rate remained almost constant between 2017 and 2019. In 2019, 21% of the population still lived with under $5.5 per person per day (in 2011 PPP), and this share is expected to increase in 2020 by 4%-5%. Poor education and health outcomes limit the contribution of human capital to inclusive growth and the pandemic likely widened this gap. As a largely service and consumption-based economy, Kosovo was particularly vulnerable to the COVID-19 shock.

To support the recovery in 2021, the country's government should strengthen compliance with pandemic preventive measures, increase treatment capacity and effectiveness, while reducing citizens' out-of-pocket costs, and boost vaccination, according to the World Bank. Targeting of social protection and private sector support measures should be improved and implementation of public projects with secured financing accelerated. To support a resilient recovery in the medium term, public spending effectiveness and the regulatory environment should be enhanced. Investment in human capital should be prioritized. In 2020, Kosovo's economic activity is estimated to contract by 6.9%, based on the World Bank's estimates, driven by a plunge in exports - principally because of a 51% drop of diaspora travel services - and investment. Consumption contributed modestly, with higher government offsetting lower private consumption. Fiscal stimulus combined with increased remittances and goods exports cushioned the contraction. Consumer price inflation decelerated in 2020 to 0.2% because of weak domestic demand and declining import prices. Formal employment weathered the impact of the downturn, but compensation and working hours were reduced. Registered unemployment increased, most likely from job losses in the informal economy. Overall, unemployment remains high at 25% of the labor force (46.9% of youth) in Q3 2020. Projections suggest a poverty increase of 4%-5% in 2020 (70-90 thousand new poor). The expected return to growth in 2021 should modestly reduce poverty as the services sector recovers.

Despite a 28.4% reduction in public investment, the budget deficit closed 2020 at 7.6% of GDP, due to lower public revenues against the contraction. Current spending increased by 18.6%, driven by pandemic-related spending of an estimated 4.4% of GDP. The deficit was financed primarily through domestic and external debt and liquidation receipts.The drop in imports and a rise in secondary income almost compensated the plunge in exports during 2020. As a result, the current account deficit (CAD) deteriorated marginally from 5.5% to 5.7% of GDP. CAD was primarily financed by net FDI inflows and other international debt-driven investment flows.

Bank deposits and bank credit increased by 11.5% and 7.1%, respectively. New loans increased only by 1.8%, reflecting restructuring activity throughout the year. Capital adequacy is above regulatory requirements, while NPLs increased by 0.7%. Forbearance measures by the Central Bank cushioned the impact of the pandemic on the financial sector.

Based on the World Bank's estimates, Kosovo's real GDP is projected to reach 4% in 2021. The recovery is expected to be gradual. Economic activity will reach pre-pandemic levels only in 2022, mainly driven by a rise in exports and consumption. Growth in goods exports should continue to be strong in the medium term, as base metal prices are expected to rise. Service exports should also recover driven by a recovery in diaspora-related tourism exports, as international travel restrictions are relaxed, and vaccination accelerates in Europe. Economic growth is projected to remain over 4% in the medium term, but downside risks to the outlook are high. The projected outlook rests on the assumption of relaxed international mobility between Europe and Kosovo, no further strict local containment measures and a recovery in Euro Area growth. There is also potential for higher growth, including through faster implementation of IFI-financed public investment.

Fiscal deficit will remain elevated in 2021 projected at 5.1% of GDP, driven by fiscal stimulus measures and the disruption in the growth trajectory induced by the pandemic. Revenues are expected to recover as growth picks up. Fiscal stimulus aimed at supporting businesses and livelihoods should be fully executed in 2021, at about 3.2% of GDP.

According to the World Bank, the CAD should remain at 5.7% of GDP in 2021 and gradually improve over the medium term. Goods' exports should increase gradually, while imports also increase on the back of higher aggregate demand. The size of the CAD will be deter-mined by the pace of remittance growth and recovery of diaspora-related tourism exports. The pandemic has intensified the developmental gaps, hence progress on structural reforms, including improvements in the design and targeting of social protection spending and regulatory environment for businesses is vital in reversing the adverse economic and social impact of the pandemic and building resilience against future negative shocks.

2.3 Turkey and Israel: The Economies of the East Med Countries

We have left for the end of this chapter the review for the economies of Turkey and Israel. Two important Mediterranean countries whose economies are markedly different from those of the other countries in SE Europe. To start with Turkey's economy is a lot larger and in size and roughly corresponds to the sum of the economies of all the other countries, EU member countries and WB6. This obviously affects energy infrastructure and energy market developments as we have already pointed out in our introduction.

Turkey's economy until recently had been performing well with a notable growth pattern and constant improvement of the standard of living. However, as it is explained further on, the Turkish lira devaluation in 2020-2021, following some unfortunate monetary policy moves, led to strong depreciation which impacted negatively the economy, a situation which exacerbated with the collapse of the tourist market in 2020 because of COVID-19. Despite of this outcome, the economy remains robust judging from its expansion in 2020 and anticipated growth in 2021.

Israel's economy is a different case all together. Despite the pandemic and geopolitical tensions in the region, the economy has managed to hold and develop. The country's finances have been strengthened by the improvement in the external balance of payments, following the growing consumption of domestically produced natural gas and the corresponding lessening of oil and coal imports and the continuing export of high tech products.

Turkey

Turkey was the only G20 country aside from China that recorded an economic expansion in 2020. However, this rapid recovery raised macroeconomic and financial stability risks. Unless addressed, these vulnerabilities will expose Turkey to heightened risk and continue to limit productivity, which has stagnated in recent years. Latest market turmoil, following the replacement of the Central Bank Governor[2], illustrates the importance of a sustained and credible focus on bringing inflation down to the target rate of 5% and bolstering the country's international reserves. Structural reforms in labor, product and financial markets, and to innovation systems can support productivity growth. Corporate sector vulnerabilities - further elevated by the pandemic and higher debt burden - present risks to banks. Developing local currency, long-term finance sources would alleviate existing imbalances in the financial system and contribute to economic growth.

The economic recovery in the second half of 2020 helped recover most of the jobs lost during the pandemic's first wave. However, jobs for informal, lower-skilled, female, and young workers remain well below their pre-pandemic levels. Furthermore, 2.6 million more individuals were out of the labor force in 2020. The poverty rate is projected to increase to 12.2% in 2020, which would mark the second successive year that poverty has increased in Turkey, from 8.5% in 2018. Based on the World Bank's data, Turkey's real GDP grew by 5.9% y-o-y in Q4 2020, completing a remarkable rebound in the second half and resulting in full-year growth of 1.8%, despite the economic fallout from the coronavirus pandemic. The recovery was driven by surging domestic demand, buoyed by credit in the second and third quarter. The authorities loosened monetary policy and delivered a stimulus program totaling 13% of GDP, most of which was supported via the banking sector in the form of partial credit guarantees and loan deferrals. Other fiscal support included social support payments to households, support for furloughed workers, tax deferrals, and other support for firms.

Growth from the implementation of the above policies came at the cost of rising prices and macro-financial vulnerabilities. Inflation trended upward, reaching 15.6% in February - the highest level in 18 months. The Turkish lira depreciated by 20% against the US dollar in 2020. From a surplus in 2019, the current account moved back into deficit ($36.7 billion or 5.1% of GDP) as tourism income evaporated, merchandise exports fell, and gold imports increased. After the central bank stepped in to finance as much as 80% of the current account deficit, foreign exchange reserves fell sharply, reaching unprecedented lows on a net basis. Deposit dollarization rose to 55%. Buoyant tax revenues resulted in a central government deficit of 3.4% of GDP in 2020, better than the planned deficit of 4.9% of GDP. Toward the end of 2020, a second wave of COVID-19 peaked, with cases reaching 30,000 a day in November. Following the re-imposition of containment measures (including masking, weekend curfews, and restaurant closures), new cases declined to around 10,000 a day by February 2021, following which, the government began easing restrictions again, based on a province-level risk assessment.

By late 2020, the authorities had also moved to address economic vulnerabilities, more than doubling interest rates between August and December, repealing exceptional regulations aimed at stimulating credit growth, and increasing transparency. This policy shift helped spur portfolio inflows, stabilize the lira, and strengthen market confidence. Credit growth decelerated sharply to near zero (13-week average) by February, and the banking sector reduced its net open foreign exchange position. Based on the World Bank's estimates, Turkey's economy is expected to grow by 5.0% in 2021 and by 4.5% in 2022 and 2023. Despite slow quarterly growth expected in 2021 - as

[2] https://www.aljazeera.com/economy/2021/5/25/turkey-removes-one-more-central-bank-deputy-governor

monetary policy remains tight and external demand weak - GDP in the second quarter will be higher than the year-earlier period when COVID-19 brought Turkey's economy to a near-standstill. These projections assume that cautious reopening continues and that there is no uncontrolled outbreak in Turkey or its major export markets, which could undermine growth.

Source: IMF World Economic Outlook (April 2021)

The lira's sharp depreciation in response to the replacement of the Central Bank Governor will impact inflation, according to banking sources. Average inflation is projected to increase in 2021 to 15.5%. The current account deficit is expected to narrow to 3.7% of GDP in 2021. The 2021 general government deficit is projected at 3.5% of GDP as the need for additional support to cushion the economic and social impact of the pandemic continues, before narrowing to 3.1% in 2022 and 2.6% in 2023 as temporary tax reductions and other government support is withdrawn. Regulatory forbearance (especially on non-performing loan definitions and capital adequacy ratio calculations) is expected to be phased out in mid-2021, after which there may be an increase in non-performing and distressed loans.

Strengthening bad loan resolution, insolvency, and out-of-court corporate debt restructuring frameworks with an effective corporate viability assessment will be critical to shield corporates and the banks from spillovers.Turkey's external risk profile is high due to its still-low level of international reserves and sizeable external financing needs. The country has limited space to manage exchange rate volatility in the event of new external shocks. The banking sector has adequate foreign exchange buffers, most of which form part of central bank international reserves.

According to the World Bank[3], simulation analysis suggests that poverty may have increased by as much as 2.1% in 2020 -equivalent to 1.6 million of new poor. The crisis pushed a similar number of people into poverty as the 2018/2019 recession. Had the government not acted swiftly to stem the social effects of COVID-19, the increase in poverty would have been three times greater. Turkey is projected to enter 2021 with the highest poverty rate since 2012. Successful poverty reduction will require ensuring that the recovery benefits informal and unskilled workers and other vulnerable groups through a policy mix of social transfers, inclusive job creation, and labor activation strategies.

Israel

The Israeli economy has recorded one of the best performances in the OECD country group in recent years. According to Santander's report[4], since the mid-2000s, Israeli real GDP growth has averaged 3.7%, mainly due to an increase in the working-age population and the participation rate. After reaching 3.4% of GDP in 2019, economic growth was abruptly halted due to the outbreak of the COVID-19 pandemic. A negative rate of -5.9% was recorded in 2020. According to the IMF's updated April 2021 forecast, real GDP growth is expected to pick up to 5.0% in 2021, depending on the post-pandemic recovery of the global economy. The exploitation of the Leviathan gas fields is, however, expected to stimulate growth. In the long term, the increase in the proportion of low-skilled Har (ultra-Orthodox Haredim) and Israeli Arab communities and of the working population (expected to fall from 25% to 40% by 2045) are potential obstacles to growth.

Building upon years of fiscal discipline and spending restraint, the Israeli economy continued to perform well in 2019. Private consumption increased 18.2% in Q4 2020, which was below the third quarter's 42.2% expansion, likely weighed on by the second lockdown early in the quarter. Government spending grew at the fastest rate on record, expanding 26.0% (Q3 2020: +8.5%, seasonally adjusted annualized rate). Meanwhile, fixed investment growth improved to 66.1% in Q4 2020, up from the 17.4% expansion in the prior quarter and driven by surging industrial investment. Based on data provided by Focus Economics , Israeli exports of goods and services fell 4.9% on a seasonally adjusted annualized rate basis in Q4 2020, which contrasted the third quarter's 67.6% expansion. Conversely, imports of goods and services bounced back, growing 88.5% in Q4 (Q3 2020: -1.3%, seasonally adjusted annualized rate basis). The reading was driven by surging car imports amid frontloading ahead of tax hikes at the start of 2021.

Israel has one of the highest living standards in the region. The average salary in Israel is similar to average salaries in Europe. However, 25% of Israelis live in poverty and inequality is relatively high, which explains the frequent protests and the pervasive current of simmering social unrest. Furthermore, households suffer from real estate prices and high costs of living (according to a study by the Taub Center, as cited by the aforementioned Santander's report, Israeli cost of living is 23% higher than the OECD average). According to the latest IMF estimates dated April 2021, the unemployment rate has risen due to the global crisis caused by the COVID-19 pandemic and reached 4.3% in 2020 and it is expected to remain at 5.0% in 2021. According to the IMF, Israel must promote its policies to ensure the social and economic integration of Arab and haredim minorities.

2.4 Discussion

The COVID-19 pandemic and related containment measures are taking a heavy toll on the global economy and will certainly affect the SEE economies, leading to much lower economic growth or even a recession. The region's economies will be affected at several levels, with tourism activity being declined in almost all SE European countries.

First, the containment measures will unequivocally affect domestic demand and supply, significantly decreasing economic activity. Supportive macroeconomic policies can partially aid the recovery of demand but cannot completely offset the economic consequences of enforced shutdowns and consumer reluctancy to spend. Second, the COVID-19 crisis has already curtailed global international travel demand and will certainly lead to a collapse in tourism ahead of the summer season.

Third, exports across the region will fall due to depressed demand, as well as disruptions in value chains. Although all economies will be affected, Romania and Serbia would likely bear the greatest cost, as their manufacturing sectors are more highly integrated into global supply chains and contribute the most to their economies in terms of value-added and employment. Fourth, a deceleration of both public and private investment can be expected, which will further inhibit economic growth. The contribution of Foreign Direct Investment (FDI) to the Western Balkan economies has been relatively sizeable over the last years, providing support for economic growth, job creation and technological progress.

Fifth, the Western Balkans and SE Europe in general rely heavily on the steady inflow of remittances, financing domestic demand and investment. In Kosovo, for instance, remittances account for 15% of overall GDP. In addition to the high volumes, the remittances are also quite concentrated in terms of source countries - Germany, Italy, Austria - further exacerbating the SEE economies' vulnerability to the crisis' impact in these economies. Remittances are likely to diminish due to travel restrictions and an increased unemployment, linked to the anticipated economic contraction in the EU.

The sustainability of growth is the top economic policy priority for the SEE countries and the driving force behind all reforms and stabilization policies adopted by the vast majority of the region's governments. The key policy priorities for the SEE region are the support of domestic demand, the confrontation of crisis legacies, such as the external shocks, and the improvement of business environment to enhance investment and long-term growth.

The regional economy is set to return to growth in H2 2021, recovering from the pandemic-induced downturn. The reopening of economies is set to buttress domestic and foreign demand; however, a sluggish labor market recovery, particularly as fiscal support measures are wound down, will limit household spending. Moreover, uncertainty regarding the pandemic clouds the outlook. The recovery in 2021 is conditional on a gradual resumption of normal activity in the region's economies and in those of their trading partners, which could be threatened by a resurgence of the pandemic.
A major hope and pillar of economic recovery in SE Europe, especially for its EU member countries, is expected to be the Recovery and Resilience Facility. More specifically, the EU member countries in SE Europe, through the submission of their national Recovery and Resilience Plans, will have access to the bloc's €750 billion recovery fund. The Recovery and Resilience Mechanism, a central element of the "Next Generation EU", was approved by European leaders in July 2020, as a main instrument for the EU's economic recovery from the crisis caused by the COVID-19 pandemic.

To sum up, all the SE European countries are now following the international developments, especially the ongoing coronavirus pandemic, and we have to observe the imminent repercussions they will have on their economies.

EU Energy and Environmental Policies and Regional Priorities

EU Energy and Environmental Policies and Regional Priorities

The main EU energy strategy is the **Energy Union Strategy**[1], published on February 25, 2015, as a key priority of the Juncker Commission (2014-2019). It aims to build an energy union that gives EU households and businesses secure, sustainable, competitive and affordable energy. Since the strategy's launch in 2015, the European Commission has published several packages of measures and regular progress reports, which monitor its implementation. The energy union builds five closely related and mutually reinforcing dimensions:

- **Security, solidarity and trust** - diversifying Europe's sources of energy and ensuring energy security through solidarity and cooperation between EU countries
- **A fully integrated internal energy market** - enabling the free flow of energy through the EU through adequate infrastructure and without technical or regulatory barriers
- **Energy efficiency** - improved energy efficiency will reduce dependence on energy imports, lower emissions, and drive jobs and growth
- **Climate action, decarbonising the economy** - the EU is committed to a quick ratification of the Paris Agreement and to retaining its leadership in the area of renewable energy
- **Research, innovation and competitiveness** - supporting breakthroughs in low-carbon and clean energy technologies by prioritising research and innovation to drive the energy transition and improve competitiveness.

The 2020 state of the energy union report[2] was published on October 14, 2020. The report looks at the energy union's contribution to EU's long-term climate goals and takes stock of the progress made in the five energy union dimensions. It also highlights how the NextGenerationEU recovery plan can support EU countries, through a number of EU funding programmes. The report is accompanied by a wide range of reports and annexes, including the individual assessments of the national climate and energy plans (NECPs), analysing the contribution each country is committed to make to the EU 2030 energy and climate targets.

On December 11, 2019, the European Commission presented the **European Green Deal**[3] – a roadmap for making the EU's economy sustainable by turning climate and environmental challenges into opportunities across all policy areas and making the transition just and inclusive for all. The European Green Deal covers all sectors of the economy, notably transport, energy, agriculture, buildings, and industries, such as steel, cement, ICT, textiles and chemicals.

On January 14, 2020, the European Commission presented the European Green Deal's Investment Plan - the **Sustainable Europe Investment Plan**- that will mobilise public investment and help to unlock private funds through EU financial instruments, notably InvestEU, which would lead to at least €1 trillion of investments.

While all Member States, regions and sectors will need to contribute to the transition, the scale of the challenge is not the same for everyone. Some regions will be particularly affected and will undergo a profound economic and social transformation. The **Just Transition Mechanism** is designed to provide tailored financial and practical support to generate the necessary investments and help affected workers in those areas.

On March 4, 2020, the European Commission proposed a **European Climate Law**[4] to ensure a climate neutral European Union by 2050. EU Institutions and Member States are collectively bound to take the necessary measures at EU and national level to meet the

[4] https://ec.europa.eu/clima/policies/eu-climate-action/law_en

target. The Climate Law includes measures to keep track of progress and adjust EU actions accordingly, based on existing systems such as the governance process for Member States' National Energy and Climate Plans, regular reports by the European Environment Agency, and the latest scientific evidence on climate change and its impacts. Progress will be reviewed every five years, in line with the global stocktake exercise under the Paris Agreement.

On July 8, 2020, the EU adopted strategies for energy system integration[5] and hydrogen[6], aiming to become climate-neutral by 2050. The plans aim to transform Europe's energy system, which accounts for 75% of the EU's greenhouse gas emissions, paving the way towards a more efficient and interconnected energy sector, driven by the twin goals of a cleaner planet and a stronger economy. (1) According to the European Commission, the two strategies present a new clean energy investment agenda, in line with the post-Covid-19 Recovery and Resilience Fund (RRF) and the European Green Deal[7]. According to EU officials, the planned investments have the potential to stimulate the economic recovery from the coronavirus crisis. In their view, they create European jobs and boost the bloc's leadership and competitiveness in strategic industries, which are crucial to Europe's resilience.

EU Executive Vice-President for the Green Deal, Frans Timmermans, said if Europe wants to become the first climate neutral continent by 2050, it needs to switch its energy systems from fossil fuels to clean. He said the strategies adopted on July 8 will bolster the European Green Deal and the green recovery, and put the EU firmly on the path of decarbonising its economy by 2050. "The new hydrogen economy can be a growth engine to help overcome the economic damage caused by COVID-19. In developing and deploying a clean hydrogen value chain, Europe will become a global frontrunner and retain its leadership in clean tech," Timmermans said.

At the same time, EU Energy Commissioner Kadri Simson noted that with 75% of the EU's greenhouse gas emissions coming from energy, the EU needs a paradigm shift to reach the stated 2030 and 2050 targets. "The EU's energy system has to become better integrated, more flexible and able to accommodate the cleanest and most cost-effective solutions. Hydrogen will play a key role in this, as falling renewable energy prices and continuous innovation make it a viable solution for a climate-neutral economy," Simson said.

The EU Strategy for Energy System Integration will provide the framework for the green energy transition, the European Commission said, adding that the current model where energy consumption in transport, industry, gas and buildings is happening in 'silos' – each with separate value chains, rules, infrastructure, planning and operations – cannot deliver climate neutrality by 2050 in a cost-efficient way; the changing costs of innovative solutions have to be integrated in the way we operate our energy system. New links between sectors must be created and technological progress exploited.

In EC's view, energy system integration means that the system is planned and operated as a whole, linking different energy carriers, infrastructures, and consumption sectors, and so by becoming connected and flexible, the system can be characterized as more efficient and can reduce costs for society. "For example, this means a system where the electricity that fuels Europe's cars could come from the solar panels on our roofs, while our buildings are kept warm with heat from a nearby factory, and the factory is fuelled by clean hydrogen produced from off-shore wind energy," they note. Hence, the EC's Energy System Integration strategy sets out 38 actions to link different energy carriers, infrastructures and sectors and exploit technological progress, while its Hydrogen Strategy will support the decarbonisation of industry, transport and other sectors across Europe, through investments, regulation,

[6] https://ec.europa.eu/energy/sites/ener/files/energy_system_integration_strategy_.pdf
[6] https://ec.europa.eu/energy/sites/ener/files/hydrogen_strategy.pdf
[7] https://eurlex.europa.eu/legal-content/EN/TXT/?qid=1576150542719&uri=COM%3A2019%3A640%3AFIN

market creation, and research and innovation. (2) According to the European Commission, this gradual transition will require a phased approach. From 2020 to 2024, the EU will support the installation of at least 6 GW of renewable hydrogen electrolysers in the EU, and the production of up to 1 million tonnes of renewable hydrogen. From 2025 to 2030, hydrogen needs to become an intrinsic part of our integrated energy system, with at least 40 GW of renewable hydrogen electrolysers and the production of up to 10 million tonnes of renewable hydrogen in the EU. From 2030 to 2050, renewable hydrogen technologies should reach maturity and be deployed at large scale across all hard-to-decarbonise sectors, the Commission said.

EU Internal Market Commissioner Thierry Breton said the European Clean Hydrogen Alliance also launched on July 8, 2020, will channel investments into hydrogen production. "It will develop a pipeline of concrete projects to support the decarbonisation efforts of European energy intensive industries such as steel and chemicals. The Alliance is strategically important for our Green Deal ambitions and the resilience of our industry," Breton said.

WindEurope hailed on July 8 the EU's decision to promote direct electrification across the whole economy and the use of renewable hydrogen in hard-to-abate sectors. "It's good these new EU Strategies recognise the primary role of direct electrification," WindEurope CEO Giles Dickson said. "Electrifying heating, transport and industry directly via renewables is the cheapest and most efficient way to decarbonise energy. Renewables are well over a third of Europe's electricity and rising. We now have to get renewable electricity into heating, transport and industry," he added.

Other important EU energy and climate policies include the **Renovation Wave Strategy**[8], presented on October 14, 2020, in order to improve the energy performance of buildings. The European Commission aims to at least double renovation rates in the next ten years and make sure they lead to higher energy and resource efficiency. This will enhance quality of life, reduce Europe's greenhouse gas emissions, foster digitalisation and improve the reuse and recycling of materials. By 2030, 35 million buildings could be renovated and up to 160,000 additional green jobs created in the construction sector, based on EC estimates.In addition, the European Commission presented on November 19, 2020 the **EU Strategy on Offshore Renewable Energy**[9]. The Strategy proposes to increase Europe's offshore wind capacity from its current level of 12 GW to at least 60 GW by 2030 and to 300 GW by 2050. The Commission aims to complement this with 40 GW of ocean energy and other emerging technologies such as floating wind and solar by 2050.

On February 24, 2021, the European Commission adopted a new **EU Strategy on Adaptation to Climate Change**[10], setting out the pathway to prepare for the unavoidable impacts of climate change. Building on the 2013 Climate Change Adaptation Strategy, the aim of the new proposals is to shift the focus from understanding the problem to developing solutions, and to move from planning to implementation.

On July 14, 2021, the European Commission presented the much awaited **"Fit for 55"** legislative package. The "55" refers to the 55% net emissions reduction target by 2030 relative to 1990 levels, which EU leaders signed off on in 2020, superseding a previous goal of a 40% reduction. The aim of the "Fit for 55" package is to update the EU's 2030 climate and energy laws to reflect this higher target. On June 24, 2021, the European Parliament voted in favor of an agreement with the EU Council on the bloc's revamped greenhouse gas emissions reduction targets for 2030 and 2050. The vote made the EU's 2030 and 2050 climate targets legally binding and cleared the way for the European Commission's package of legislative proposals on climate and energy on July 14,

8 https://ec.europa.eu/energy/sites/ener/files/eu_renovation_wave_strategy.pdf
9 https://ec.europa.eu/commission/presscorner/detail/en/ip_20_2096
10 https://ec.europa.eu/clima/sites/clima/files/adaptation/what/docs/eu_strategy_2021.pdf

2020, which aimed to deliver on the overarching target. The vote means the Parliament has given its final rubber stamp on a provisional deal it reached with the EU Council April 21, 2021.

The "Fit for 55" package consists of a set of inter-connected proposals, which all drive towards the same goal of ensuring a fair, competitive and green transition by 2030 and beyond. Where possible, existing legislation is made more ambitious and where needed new proposals are put on the table. Overall, the package strengthens eight existing pieces of legislation and presents five new initiatives, across a range of policy areas and economic sectors: climate, energy and fuels, transport, buildings, land use and forestry. The legislative proposals are backed by impact assessment analysis, which takes into account the interconnection of the overall package. The analysis shows that an over-reliance on strengthened regulatory policies would lead to unnecessarily high economic burdens, while carbon pricing alone would not overcome persistent market failures and non-market barriers. The chosen policy mix is therefore a careful balance between pricing, targets, standards and support measures[11].

Table 3.1 **The Selected Policy Mix of the "Fit for 55" Package**

Pricing	Targets	Rules
•Stronger Emissions Trading System including in aviation •Extending Emissions Trading to maritime, road transport, and buildings •Updated Energy taxation Directive •New Carbon Border Adjustment Mechanism	•Updated Effort Sharing Regulation •Updated Land Use Land Use Change and Forestry Regulation •Updated Renewable Energy Directive •Updated Energy Efficiency Directive	•Stricter CO_2 performance for cars & vans •New infrastructure for alternative fuels •ReFuelEU: More sustainable aviation fuels •FuelEU: Cleaner maritime fuels
Support measures		
• Using revenues and regulations to promote innovation, build solidarity and mitigate impacts for the vulnerable, notably through the new **Social Climate Fund and enhanced Modernisation and Innovation Funds.**		

Source: European Commission

This Chapter also includes two special European energy policies that need to be further highlighted, as they are expected to play a vital role towards carbon neutrality by 2050: (a) EU Energy Taxonomy, including decarbonization issues in SE Europe and (b) the EU's Recovery and Resilience Facility.

3.1 2030 EU Climate and Energy Targets

For reference purposes, the current key EU Climate and Energy targets for 2030 are summarized as follows (3):

- At least 40% cuts in GHG emissions (from 1990 levels)
- At least 32% share of renewable energy
- At least 32.5% improvement in energy efficiency

Figure 3. 1 **Current 2020 and 2030 EU Agreed Climate and Energy Targets**

	GREENHOUSE GAS EMISSIONS	RENEWABLE ENERGY	ENERGY EFFICIENCY	INTER-CONNECTION	CLIMATE IN EU-FUNDED PROGRAMMES	CO2 FROM:
2020	-20%	20%	20%	10%	2014-2020 20%	
2030	≤ -40%	≤ 32%	≤ 32.5%	15%	2021-2027 25%	CARS -37.5% Vans -31% Lorries -30%

Source: European Commission

Achieving a 55% GHG emissions reduction by 2030 requires an increased share of renewable energy in the range of 38% to 40% of gross final consumption, according to Commission President Ursula von der Leyen in her first State of the European Union speech (4).

The power sector will continue to move away from fossil fuels, which would generate less than 20% of the EU's electricity by 2030, while renewables would supply around two-thirds of the EU's electricity. The Commission's Impact Assessment indicates that final and primary energy consumption would further fall by 2030, while achieving savings of 36%-37% on energy efficiency. In heating and cooling, renewables could achieve around 40% penetration in 2030, mainly through switching fuels towards renewable heating solutions of which heat pumps are the fastest growing application area. Buildings will become more energy efficient and rely less on fossil fuels for heating and cooling.

[11] https://ec.europa.eu/info/sites/default/files/chapeau_communication.pdf

As a result, by 2030, emissions from buildings would decrease by around 60% compared to 2015, the European Commission notes.

In the transport sector, as calculated in the Renewable Energy Directive, renewables could reach around 24% through further development and deployment of electric vehicles, advanced biofuels and other renewable and low carbon fuels. Revised CO_2 emission standards for cars and vans will ensure enough clean cars are available on the market. Supporting this transition will require a corresponding roll-out of recharging and refuelling infrastructure by 2030. As part of the Green Deal, the European Commission wants to place 1 million new charging points across the EU. Initially, the 2030 target for greenhouse gas (GHG) emissions reduction, compared to 1990 levels, in the EU was 40%.
On September 17, 2020, the European Commission proposed to raise that to 55%, but the EU Parliament on October 6 upped the ante, voting to raise the bloc's climate target to 60%, putting capitals under pressure.

Some Member States argued that the European Commission's proposal to increase the 2030 target from 40% to at least 55% does not adequately reflect their different starting points. Moreover, they consider that the proposal does not provide sufficient burden-sharing mechanisms based on the compensation for Member States with coal-dependent economies.

The vote in the European Parliament in favour of increasing the target to 60% challenged Member States with high GHG emissions and lower GDP per capita. These Member States were concerned that the burden of the transition cost will not be evenly distributed across the European Union, which might reinforce or even create new inequalities within the EU. The European Commission, Member States and European Parliament finally reached agreement on April 21, 2021 to raise the emissions reduction target to 55% relative to 1990 levels. But getting there wasn't easy.

3.2 Opposition from EU Member States

On October 23, 2020, EU environment ministers struck a deal to make the bloc's 2050 net-zero emissions target legally binding, but left a decision on a 2030 emissions-cutting target for leaders to discuss in December. None of the 27 member countries rejected the bill, although Bulgaria abstained. (5) Earlier, the European Commission said that the bloc needs a cut of at least 55% by 2030, against 1990 levels, in order to achieve the goal of net zero emissions by 2050, which all 27 countries, bar coal-dependent Poland, had committed to. The leaders did not endorse a specific 2030 target on October 15, but agreed to "return to the issue" in December, with the aim of finalising the goal by year-end. (6)

The EU takes decisions by unanimity. Once countries agree a common position on the 2030 target, they must strike a deal with the European Parliament, which proposed a 60% emissions cut. Leaders agreed to postpone the deal until countries have more information on the national impact of the target. That placated Poland, which said it could not back a new climate goal without this analysis.

Accordingly, the Council of EU leaders invited the Commission "to conduct in-depth consultations with member states to assess the specific situations and to provide more information about the impact at member states' level", a joint statement said. (7)

It also confirmed the 2030 emissions-cutting target would be met "collectively" at EU level. This could help convince the Czech Republic, which recently said it could support an EU-wide 55% emissions cut by 2030, but that it could not achieve that goal itself at a national level. Roughly half of the EU's 27 members - including Germany, France, Spain, Latvia and Denmark - said they supported the "at least 55%" goal. Needless to point out that the target would usher in sweeping changes to EU policies, including tighter car emissions standards and higher carbon costs for industry and airlines.

[12] https://www.ecologic.eu/sites/default/files/publication/2020/eu2030-ia-analysis_final.pdf

Increasing the European Union's 2030 emissions reduction target from 40% to at least 55% would require the bloc to almost entirely phase out coal by that date, according to a new report from the consultancy Climact and think tank Ecologic[12]. The analysis of the European Commission's impact assessment, accompanying its proposal to increase the target last September, found that coal could only represent around 2% of the EU's energy mix under any scenario meeting the target, down from the current 15%. (8)

This would mean many EU countries would have to dramatically adjust their coal phase-out plans. For instance, Germany has a plan in place which would see coal phased out by 2038 at the latest. Poland, which is heavily reliant on coal and has set a phase-out date for 2049, may have a difficult time meeting such a target - or at least have difficulty getting it accepted politically. Together, Poland and Germany account for half of the EU's coal emissions. Most EU countries have set coal phase-out plans that would end its use before 2030. Romania, Bulgaria, Czech Republic, Slovenia and Croatia have not set any specific coal phase-out date yet. Instead they are openly making noises insisting that a compensation arrangement is agreed beforehand, prior to committing to any coal phase-out plan.

At the same time, the Commission does not agree that meeting the 55% target would require a near-complete phase-out from coal. According to its impact assessment, coal would only have to be reduced by 70% by 2030 compared to 2015. Oil and gas, on the other hand, would have to be reduced by 30% and 25% respectively. Conservatives in the European Parliament's EPP group, a pan-European political family that includes Germany's Angela Merkel and Commission President Ursula von der Leyen as members, are concerned that the 55% target is already too ambitious. Climate campaigners, on the other hand, say 55% will not be enough to meet the emissions reduction trajectory required to meet the EU's commitments under the Paris Agreement. They say a 65% target would be needed. "It is important in these times to submit proposals that are in line with what scientists said it is necessary", argues Imke Lübbeke from the campaign group WWF. (9)

As if a coal phase-out was not enough, the EC's latest thinking and indirect actions (i.e. EIB, EU Taxonomy) suggest that next in line would be a complete gas phase out (see "Policy Inconsistencies Concerning Gas Use in SE Europe" in Special Focus 1: EU Energy Taxonomy). That would clearly undermine efforts by SEE countries, which will be trying to decarbonize by first transitioning to gas.

3.3 The Case of SE Europe

The current energy issues of the SE European countries, including EU and Energy Community member states, concern primarily the further use of indigenous resources, both conventional and renewable, which inevitably give rise to different approaches at local level, often leading to conflicting policy views.

One major issue is the sustained development of coal and lignite resources, which are abundant in Greece, Bulgaria, Kosovo, Serbia, Bosnia and Herzegovina and Turkey. Solid fuel use in the power generation sector in these countries is responsible for many thousands of jobs, and forms the basis of an extensive industrial base. Yet, there is a disturbing lack of well thought-out regional policies in SE Europe in such areas as Carbon Capture and Storage (CCS) and Carbon Capture, Utilization and Storage (CCUS) that could see the prolongation in the life of local coal and lignite industries and the smooth transition to decarbonized power generation.

Today, regional energy policies, as defined in the context of the Energy Union, do not leave much room for developing regionally advantageous policies, including coal use through CCS. The phasing out of all CO_2 generating plants by 2030 at the latest, is a clear target pursued by the EU.

[12] https://www.ecologic.eu/sites/default/files/publication/2020/eu2030-ia-analysis_final.pdf

Therefore, we have a potentially explosive situation with wide ranging social implications if lignite- and coal-fired power plants start closing down en masse, sending thousands of people to early retirement or unemployment.

Politics the EU and SE Europe have become polarised over past decade by inequality and immigration. The forced closure of coal- and lignite-fired power plants and mines in many countries will help to undermine economic development and will most likely give rise to widespread social unrest, creating a new source of unhappiness for populist parties to exploit. A similar but less disturbing situation could arise with oil and gas exploration and production activities. Several countries in the SE European region are actively seeking to explore oil and gas deposits, despite the ongoing COVID-19 pandemic and the huge impact on oil demand and prices, since this region as a whole is a net hydrocarbon importer (see Chapter 9). Almost all countries in the region are reporting promising hydrocarbon deposits, with some of them, notably Albania, Croatia, Serbia and Romania, having developed extensive production facilities and with Greece, Montenegro, Bulgaria, Cyprus and recently Turkey[13] having announced ambitious plans for oil and gas production and exports.

A potentially conflicted situation could even arise in the benign field of renewables (RES) as many countries in SE Europe have abundant solar, wind, geothermal, biomass and hydro potential (see Table 3.2), which they will seek to develop further to the fullest possible extent. With SE Europe as a whole possessing a huge excess capacity of RES, its rapid exploitation in the near future may lead to countries seeking ways to export competitively priced RES-generated electricity to central and northern Europe.

Even if we were to overcome the present lack of appropriate transmission infrastructure, at some point potential RES electricity sellers could be forced to offer prohibitively low tariffs. Alternatively, electricity market operators could decline Mediterranean electricity inputs as has already happened in the case of the ill-fated Helios project (10).

Table 3. 2 **Technical Potential for Utility-scale Solar PV, Wind and Hydropower in the Electricity Sector in SE Europe (TJ)**

Source: IRENA [14]

As analysed in IENE's "SE Europe Energy Outlook 2016-2017" study (11) and still valid today, the energy policies of most countries in the SE European region seem to amount to the following set of priorities:

1. Further large-scale development of coal and lignite resources without any CCS/CCUS provisions and plans, followed by gas use
2. Promotion of oil and gas exploration activities onshore and offshore aiming towards maximizing production in the mid- and long-term
3. Developing further renewables in all application areas – solar, wind, biomass, hydro and geothermal – but without necessarily adhering to the specific ceiling targets set by the EU
4. Promoting energy efficiency, focusing primarily on the building sector
5. Developing interconnectivity of electricity and gas systems
6. Diversifying energy supply routes and supplies

[13] Bektas, C. (2020), "Turkey discovers 320bcm of natural gas reserves in Black Sea", https://www.icis.com/explore/resources/news/2020/08/21/10543949/turkey-discovers-320bcm-of-natural-gas-reserves-in-black-sea

[14] https://www.irena.org/-/media/Files/IRENA/Agency/Publication/2019/Dec/IRENA_Market_Analysis_SEE_2019.pdf

7. Reducing CO_2 levels by implementing new, low carbon technologies, and higher penetration of cleaner fuels in the energy and electricity mix

If countries in the region could agree to reverse their current coal-centred power generation priorities, we may start to see the region's natural advantages in clean energy coming to the fore. For example, the West Balkans have attractive assets for supporting Europe's energy transition: (a) large opencast coal mines with excellent grid infrastructure that can be used for industrial solar, wind, geothermal and biomass activities, (b) low labour costs, (c) engineering skills and (d) geographic proximity to advanced industrial economies with rising energy demand. With the right incentives, these assets could attract investments in the new wave of low-carbon industries and further contribute to the European industrial transition. The EU could extend several international co-operation initiatives to include the Western Balkans in the European Green Deal. Among them are the Energy Community, the European Network of Transmission System Operators for Electricity, the Regional Cooperation Centre, Central and South Eastern Europe Energy Connectivity, the Berlin Process, and others. Each of these brings value and tools for achieving the required energy transformation, and for guiding the SEE region towards hosting modern low-carbon, high added-value industries.

International financial institutions, such as the EIB, the EBRD and the World Bank could play key role in this energy transformation of SE Europe. Most of these organisations follow strong climate-aligned policies. (Recently, the EIB branded itself the "European climate bank", pulled out of investment in fossil fuel projects and announced that it "will align all financing activities with the goals of the Paris Agreement from the end of 2020"). (12)

If the EU really wants to maximise the impact of the European Green Deal and make it economically more attractive to all governments, it should incorporate the Western Balkans and ensure that the countries there are part of the negotiation process. In this way, the EU will not only guide the region towards the 2030 and 2050 targets. It would also be able to extract the maximum value the Western Balkans could offer. This will make the European Green Deal an all-encompassing one, based on a clear mutual interest in which the Balkans will not fall into the usual role of a receiver of policy and a reluctant follower of regulations, but will instead be an active contributor.

To achieve this, the West Balkans countries themselves should consider teaming up as an inter-governmental negotiating bloc. They could then assemble an international technical assistance team that would help negotiators evaluate the clean economy assets of the region and identify the most economically beneficial paths towards rapid greenhouse gas reduction.

Discussion

The COVID-19 crisis, the EU energy system integration process and hydrogen strategies, accelerated by the Recovery and Resilience Fund and the European Green Deal, are creating huge opportunities for increasing RES penetration in the SE European energy and electricity mix. The green stimulus packages could accelerate the switch to renewable energy in SE Europe, attracting numerous investments and creating new jobs, while new green technologies, such as green hydrogen, could be very important complements to renewable-based electricity.

To ensure sustained RES investment, it is essential to create an enabling environment by introducing appropriate and dedicated policies. The region has indeed proved that it can attract investment when supporting policies and measures are in place. These measures should go beyond mere direct RES support and include, in addition, system regulation and integration with the everyday life of energy consumers. The transformation of the existing polluting SEE energy system into a sustainable one should be based on localised policies and differentiated energy sources of higher energy efficiency, with a view towards tapping hydrogen generation. Energy cooperation between the various countries in the region is of paramount importance in order to introduce lasting changes aiming towards sustainability. Hydrogen produced from renewables could play a decisive role in achieving such sustainability and should be examined in great detail for each different country of the region.

However, energy sector regulations in the region have historically favoured and subsidised fossil fuels. Reversing such long-held attitudes and creating a favourable regulatory and licensing framework for RES would require drastic reforms. Some are already underway (e.g. see Greece's aggressive decarbonization programme). International agreements, such as the Energy Community Treaty, the EU Renewable Energy Directives and the Paris Agreement, have provided some stimulus. The combination of high RES potential, falling renewable energy costs and new policies and regulations in the energy sector make SE Europe ideal for large-scale RES deployment. However, sound policies rooted in the recognition of the socio-economic impact of the energy sector and making allowance for proper financial co-operation are needed to fully achieve the energy transition in the region.

IRENA (13) estimates that shifting the regional energy system to RES would increase the economy of SE Europe by 2% per annum until 2040 and 1% from then on until 2050, compared to a business-as-usual (BAU) scenario, translating into a cumulative gain of more than $485 billion. The creation of new jobs in RES would also help tackle long-standing unemployment and brain drain issues. The inclusion of social benefits, such as improvements in health and air quality, ensures that potential gains further outweigh additional costs. According to certain scenarios, current commitments and policies at global level are expected to lead to a global temperature increase of 3°C-4°C by the end of the 21st century, a catastrophic scenario involving estimated losses for the EU alone of more than €175 billion every year by mid-century, based on the European Commission's estimates.

To keep the 1.5°C goal of the Paris Agreement within reach and prevent the more dangerous and radical climate change repercussions, the EC says that a substantially increased climate target of at least 65% emission cuts by 2030 should be adopted, which it considers the only target in line with the latest science available and the United Nations' equity principles. This is well beyond the "at least 55% target" of the European Commission. The European Parliament called for 60% emission cuts and Denmark, Finland and Sweden pledged their support for 60%-65% in the Council discussions. (14)

However, a recent joint CAN Europe and Ember study (15), which has analysed the National Energy and Climate Plans (NECPs) of seven EU Member States (Bulgaria, Croatia, the Czech Republic, Germany, Poland, Romania and Slovenia) in line to receive the lion's share of the Just Transition Fund, points out that these countries do not have any plans to phase-out coal in the next decade; though their NECPs show that a number of them is also planning an increased role for gas in their electricity transitions. Of the eleven countries expected to phase-out coal by 2030, the study indicates that only four (Greece, Hungary, Ireland and Italy) are planning a significant coal-to-gas transition.

According to latest euro thinking, the EU must achieve climate neutrality by 2050 in order to do its fair share under the Paris Agreement and to limit the global temperature increase to 1.5°C. This means that all Member States should phase out coal by 2030 and all fossil fuels by 2050 at the latest, according to the CAN Europe/Ember study. A close look at the NECPs shows that several Member States are not in line with the European 2050 climate neutrality objective or the proposed new high targets by 2030. To sum up, although the new 2030 EU Climate and Energy Targets sound really ambitious, the current status of most EU Member States indicates that a lot more work needs to be done. Hence, it is highly debateable whether these new sky high targets can actually be achieved under present policies.

Special Focus 1: EU Energy Taxonomy

In order to meet the EU's climate and energy targets for 2030, in line with the European Green Deal, it is important to direct investments towards sustainable projects and activities. "The current COVID-19 pandemic has reinforced the need to redirect capital flows towards sustainable projects in order to make our economies, businesses and societies, in particular health systems, more resilient against climate and environmental shocks and risks with clear co-benefits for health", underlines the EC. (1)

To achieve this, a common language and a clear definition of what is "sustainable" is needed. This is why the EU's action plan on financing sustainable growth called for the creation of a common classification system for sustainable economic activities, otherwise known as "EU taxonomy".

What is the EU Taxonomy?

The EC believes that its taxonomy is an important tool to scale up sustainable investment and implement the European Green Deal. It is expected to create security for investors, prevent greenwashing[15], help companies plan their transition, mitigate market fragmentation and eventually help shift investments where they are most needed.

Taxonomy Regulation and Delegated Acts

The Taxonomy Regulation[16] was published in the Official Journal of the European Union on 22 June 2020 and entered into force on 12 July 2020. It establishes six environmental objectives:

1. Climate change mitigation
2. Climate change adaptation
3. The sustainable use and protection of water and marine resources
4. The transition to a circular economy
5. Pollution prevention and control
6. The protection and restoration of biodiversity and ecosystems

Different means can be required for an activity to make a substantial contribution to each objective. The Taxonomy Regulation tasks the Commission with establishing the actual list of environmentally sustainable activities by defining technical screening criteria for each environmental objective through delegated acts. Currently, there appear to be two energy subsectors - nuclear power and natural gas - whose status as environmentally sustainable forms of energy remain in doubt and hence their classification is at stake.

Assessment of Nuclear Energy

In 2020, the European Commission launched an in-depth investigation to assess whether to include nuclear energy in the EU taxonomy of environmentally sustainable activities. As the first step, the Joint Research Centre, the in-house science and knowledge service of the Commission, drafted a technical report on the "do no significant harm" aspects of nuclear energy. This publication is a Science for Policy report by the JRC, which aims to provide evidence-based scientific support to the European policymaking process.

It does not imply a policy position of the European Commission. The report will now be reviewed by two sets of experts, the Group of Experts on radiation protection and waste management under Article 31 of the Euratom Treaty, as well as the Scientific Committee on Health, Environmental and Emerging Risks on environmental impacts. Their reports are considered as vital as the JRC's report for the Commission's decision. According to a leaked document cited by Euractiv (2), experts tasked with assessing whether the European Union should label nuclear power as a green investment will say that the fuel qualifies as sustainable.

[15] Greenwashing is considered an unsubstantiated claim to deceive consumers into believing that a company's products are environmentally friendly.
[16] https://ec.europa.eu/info/law/sustainable-finance-taxonomy-regulation-eu-2020-852_en

EU countries are split concerning nuclear. A group of seven EU countries, including France, Hungary and Poland, urged the Commission to support nuclear power in policies and taxonomy. Other states, including Austria, and some environmental groups, oppose the fuel, pointing to its hazardous waste and the delays and spiralling costs of recent projects.

Assessment of Natural Gas

The European Union reportedly plans to label some gas-fired power plants as sustainable investments, after an initial proposal to deny them a green label provoked a backlash from a group of 10 EU member states.

The European Commission's new proposal, shared with EU countries on March 20, 2021, would class gas-fuelled plants that generate power plus heating or cooling as a green investment if strict conditions on emissions are met and the plants are operating by 2025. EU countries are split between those who say that such a decision would imply greenwashing, and those who see gas as crucial for them to abandon higher-polluting coal. (3)

It is an example of how mired taxonomy has become in disputes between EU countries over how to treat investments in natural gas, forcing the Commission to rewrite its original proposal dating to November 2020. Given the EU's negative assessment of natural gas thus far, and the EIB's binding decision to suspend funding to gas related projects from 1 January 2021, the questions surrounding the sustainability and viability of gas investments acquire new impetus.

Natural gas, a fossil fuel, produces roughly half the carbon dioxide emissions of coal when burned in a power plant. Countries including Poland, Germany and Greece plan to use gas to wean themselves off the more polluting fuel. However, gas is not emissions-free and leaks of potent planet-warming methane from gas infrastructure could cancel out the benefits of switching to gas from coal altogether.

However, from among current policy options, the switch from coal to gas for power generation offers the single most important and readily available way to halve power generation's emissions, and this constitutes a bold move towards GHG emission reduction. This is particularly important for SE Europe, where coal and lignite still have dominant role in power generation. Here, gas appears to be the only quick way to reduce substantially GHG emissions.

Strict Conditions

Under the draft plan, gas plants that generate power and also provide heating or cooling can be classed as a green investment if they replace a high-emitting fossil fuel-based facility and result in a cut in greenhouse gas emissions of at least 50% per kWh. The gas plant must be operating by 2025, have the potential to use low-carbon fuels in future (e.g. biomass, geothermal) and emit no more than 270 grams of CO_2 equivalent per kWh of energy.

For plants only producing power, or those that also provide heating or cooling but do not replace a more polluting plant, the Commission stuck to its plan to restrict the green label to plants with life-cycle emissions below 100g of CO_2 equivalent per kWh, according to the draft document. That means gas-fired power plants operating now would need to add technology to capture their emissions in order to qualify.

Critique on EU Taxonomy

In June 2020, following protracted negotiations, the European Parliament adopted at second reading the compromise regulation for the establishment of an EU framework (the so-called 'taxonomy') to facilitate sustainable investment. Years of intensive work and engagement with strategic stakeholders, since the publication of the Action Plan on Financing for Sustainable Growth in March 2018, led to an "ambitious" sustainable finance strategy with one key priority in line with EU solidarity: to leave no industry nor Member State behind.

The next step is the development of delegated acts establishing realistic and fair technical screening criteria and thresholds for sustainable economic activities eligible for financial support. The Commission's proposed delegated act for the EU Taxonomy for Sustainable Finance, released in December 2020, failed to deliver the promised solidarity priority.

Despite official public consultations carried out by the European Commission, the delegated act ignored the priorities of numerous stakeholders, from the aluminium and raw materials industries to the refining and energy sectors. It also left some member states frustrated by the Commission's disregard for their right to decide on their energy mix and appropriate technologies to achieve the 2030 climate target.

A leaked revised proposal, available since the second half of March 2021, still fails to meet the industry's needs – although a number of activities is now fully taxonomy-eligible. Nevertheless, the Commission's revised draft delegated act is, as it stands, "an ineffective plan for supporting businesses and member states across the Union in their attempt to transition towards sustainability", note Members of the European Parliament. (4)

A main criticism leveled against the Commission is that the set benchmarks narrow down the basket of technological climate solutions rather than broadening it. The revised delegated act still does not explicitly include liquid and gaseous transport fuels of non-biological origin and Recycled Carbon Fuels – even though these play a critical role in meeting climate goals. This clearly limits the solutions available to reduce CO_2 emissions in, for instance, the transport sector where electrification is not always technically possible. In practice, this means that we are jeopardising the sector's ability to remain competitive by limiting its access to diversified, affordable and sustainable energy. All low carbon liquid fuels (LCLF), alongside electrification and hydrogen technologies, are crucial in achieving carbon neutrality for all transport modes.

The European Commission should look to facilitate, rather than hinder, investments for the decarbonisation of European industry, note industry experts. By leveraging the technological expertise of the EU refining industry, they say, we could step up the ongoing green transformation and foster investments in promising technologies, such as sustainable liquid biofuels and all hydrogen-derived synthetic fuels. Feedback from member states and stakeholders to the December draft taxonomy criteria and thresholds highlights these concerns, which go unaddressed in the Commission's leaked revision.

Discussion

With the Commission's final taxonomy proposal still pending, the task at hand is to ensure that criteria and thresholds broaden the scope of technological climate solutions. The EU taxonomy has the potential to be a game-changer, but it must adopt a holistic approach, examining all possible solutions to meet climate objectives, moving beyond labels such as a "brown list" that appear to dictate what are "good" and "bad" technologies. "We need to ensure that there is a level playing field when comparing various technologies, especially low-carbon technologies for fuels, petrochemical feedstock, and other refinery products. Life-cycle analysis and impact assessments are promising methods to achieve fairness and accuracy, and they need to apply horizontally", note industry sources.

Launching a "Renewable and Low-Carbon Fuel Value Chain Alliance", mentioned by the Commission in its December 2020 Sustainable and Smart Mobility Strategy, would be a pragmatic starting point for a broad reflection on these issues with stakeholders involved in aviation, refining, marine, and road transport.
With the right mix of enabling sustainable finance conditions, the EU needs to send clear, long-term signals to guide businesses and investors towards sustainable growth. But for this to be efficient, the full engagement of all actors, from EU institutions and civil society to industry, is absolutely necessary.

Only then can a realistic and fair EU Taxonomy that drives the EU towards an affordable and pragmatic transition be achieved.

There is also a much broader critique at play. This has to do with EC's increasingly micromanagerial attitude and bureaucratic overreach. Leading economists argue that the EU's obsession with constantly expanding a list of prohibited climate-sensitive activities and precise guidance in core power generation is reminiscent of Soviet-era central planning.

Hence, the EC's argument that in order to achieve lower emissions and adopt clean technologies we need to strictly control the majority of economic activity reveals a departure from the liberal economy, which European leaders claim as a major EU achievement.

Special Focus 2: EU's Recovery and Resilience Facility

According to the European Commission (1), the Recovery and Resilience Facility (RRF) will make €672.5 billion in loans and grants available to support reforms and investments undertaken by Member States. The aim is to mitigate the economic and social impact of the coronavirus pandemic and make European economies and societies more sustainable, resilient and better prepared for the challenges and opportunities of the green and digital transitions. The RRF entered into force on February 19, 2021.

Figure 3. 2 **EU's Recovery and Resilience Facility**

Source: European Commission

The Facility and NextGenerationEU

The Facility is the centerpiece of NextGenerationEU, billed as a temporary recovery instrument that allows the European Commission to raise funds to help member states repair the immediate damage of the coronavirus pandemic. The Facility is also closely aligned with the Commission's priorities ensuring in the long-term a sustainable and inclusive recovery that promotes the green and digital transitions.

National Recovery and Resilience Plans

Member States will prepare recovery and resilience plans that set out a coherent package of reforms and public investment projects. To benefit from the support of the Facility, these reforms and investments should be implemented by 2026.

The plans should effectively address challenges identified in the European Semester, particularly the country-specific recommendations adopted by the Council. The plans should also include measures to address the challenges and reap the benefits of the green and digital transitions. Each plan is expected to contribute to the four dimensions outlined in the 2021 Annual Sustainable Growth Strategy, which launched this year's European Semester cycle.

- Environmental sustainability
- Productivity
- Fairness
- Macroeconomic stability

The Facility is an opportunity to create European flagship areas for investments and reforms with tangible benefits for the economy and citizens across the EU. These should address issues that need significant investment to create jobs and growth, and which are needed for the green and digital transitions. The Commission strongly encourages Member States to put forward investment and reform plans in the areas shown in Figure 3.3.

Figure 3. 3 **Flagship Areas for Investments & Reforms**

Source: European Commission

For each of the flagships, there are EU-wide ambitions:

1. **Power up:** Support the building and sector integration of almost 40% of the 500 GW of renewable power generation needed by 2030, support the installment of 6 GW of electrolyser capacity and the production and transportation of 1 million tonnes of renewable hydrogen across the EU by 2025.
2. **Renovate:** By 2025, contribute to the doubling of the renovation rate and the fostering of deep renovation.
3. **Recharge and refuel:** By 2025, aim to build one out of the three million charging points needed in 2030 and half of the 1000 hydrogen stations needed.
4. **Connect:** Ensure that by 2025 there is the widest possible uninterrupted 5G coverage for all areas, including in rural and remote areas.
5. **Modernise:** By 2025, ensure the provision of a European digital identity (e-ID) and public administrations should be providing interoperable, personalised and user-friendly digital public services. In addition, public administrations should undertake reforms and investments to (re-)design processes, procedures and civil service according to best practices.
6. **Scale-up:** By 2025, double the production of semi-conductors in Europe, to produce 10 times more energy efficient processors and to double the share of EU companies using advanced cloud services and big data (from 16% today)
7. **Reskill and upskill:** By 2025, 50% of the adult population should participate in training each year. By 2025, the share of Europeans aged 16 to 74 with basic digital skills should increase to reach 70%. Education systems needs to be further adapted to the challenges of the 21st century. Member States should ensure that pupils' digital competence is significantly improved, in order to reduce the share of 13-14 year old students who underperform in computer and information literacy to under 15%. By 2025, at least four in five VET graduates should be employed and three in five should benefit from on-the job-training.

For each flagship to which a plan contributes, Member States are invited to provide an analysis of the existing national challenges (including the existence of market or systemic failures). In this regard, they are invited to describe their status quo (existing national strategies and targets) and how they can be further developed to meet the 2025 EU-wide ambitions of each flagship. Member States are invited to describe the relevant reforms and investments supported by the Facility.

This description may include the delivery models to implement the measures and the main actors involved. This includes how they would act as investments multipliers, contribute to employment creation and contribute towards creating beneficiaries who will co-finance projects and minimise competition distortions. Flagships can also be implemented through multi-country projects.

Green and Digital Priorities

The Recovery and Resilience Facility offers an unprecedented opportunity to speed up the recovery in Europe and reinforce the commitment to the twin transitions: green and digital. The Commission will assess the national plans against the targets shown in Figure 3.4.

Figure 3. 4 **Twin Transitions: Green and Digital**

Timetable

The European Semester and the Recovery and Resilience Facility are intrinsically linked. The publication of the 2021 Annual Sustainable Growth Strategy launched this year's European Semester. It continues last year's growth strategy based on the European Green Deal and the concept of competitive sustainability.The Commission will assess recovery and resilience plans against the country-specific recommendations. As the European Semester and the Facility will overlap, it is necessary to temporarily adapt the European Semester. Member States are therefore encouraged to submit their national reform programmes and their recovery and resilience plans in a single integrated document, which will provide an overview of the reforms and investments that the Member States plan to undertake in the coming years, in line with the objectives of the Facility.

Special Focus 3: Decarbonisation in SE Europe

Lately, decarbonisation as a concept and a coordinated set of actions has come to dominate Europe's current and long-term (i.e. 2030 and 2050) energy strategies. When considering SE European energy policy, decarbonisation will come to play an important role as it affects the whole spectrum of energy - from power generation to transport, building, industry, trade and services sectors. The ultimate objective is the reduction of Greenhouse Gas (GHG) emissions. The power sector is expected to play central role in the decarbonization process, as it is in a position to deliver fast and visible benefits, given the high volume of gases it produces.

Decarbonisation in the case of power generation means reduction of the sector's carbon intensity, which in turn means decline of the emissions per unit of electricity generated. Decarbonisation is of particular importance for coal-intensive regions, such as SE Europe, in order to transit into a "cleaner" energy mix. A gradual decarbonisation of the power sector can be achieved by increasing the share of low-carbon energy sources, like renewables and nuclear, as well as by capping GHG emissions from fossil fuel power stations through Carbon Capture and Storage (CCS) technology and Carbon Capture and Utilisation (CCU). A shift from "dirtier" fossil fuels, like coal (which emits on average 900g CO_2/kWh), to lower emissions fuels, like gas (which emits about 400g CO_2/kWh) and renewables, can also help to reduce power plant emissions. (1)

Reaching climate neutrality by 2050, as envisioned by the European Commission's strategic long-term vision, requires timely decarbonisation of the European energy sector, including a complete phase-out of coal (see Map 3.1). This will particularly affect regions which are dependent on the coal sector and other high-carbon industries, as they will have to follow a transition phase to low-carbon economies in the coming decades. This briefing offers a deep dive into the positioning of key stakeholders as well as opportunities and challenges for a transition away from coal in the coal-dependent SE European region.

Most governments in SE Europe, in contrast to the rest of Europe, remain committed to continuing coal use. Greece is until now the only country in SE Europe that is expected to shut down all its lignite-fired power plants by 2028[17], while North Macedonia's coal phase-out plan is still under discussion[18]. Based on IENE's estimates, the share of solid fuels for power generation is anticipated to hold its present position if not increase in several countries of the region (most notably in Serbia, Kosovo, Croatia, Bosnia and Herzegovina, Montenegro and Turkey[19]) over the next 10-15 years, as these countries will struggle to meet increasing energy demand. Hence, the road towards decarbonisation and the transition to a "greener" future in SE Europe, with higher use of natural gas and renewables (RES), appears difficult, if not uncertain, in comparison to the rest of Europe.

It seems that a far more realistic approach towards decarbonisation is required in the case of SE Europe. The necessity for such an approach is based on the fact that reforms are not easily being implemented, as there is a lack of social acceptance or of political will, or both.

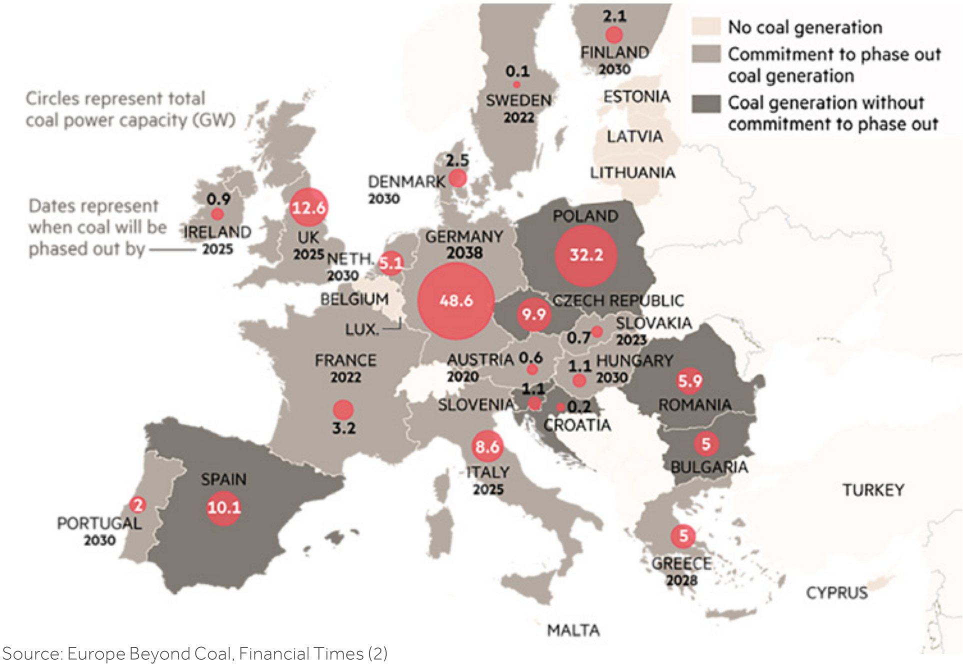
[17] In December 2019, Greece's Public Power Corporation (PPC) decided to cease operating all but one of its existing lignite-fired power plants by 2023. The only lignite-fired power plant remaining until 2028 is Ptolemaida V, which is currently under construction. PPC is now looking for a fuel conversion at the facility for lignite-free operation beyond 2028. Natural gas, biomass and waste-to-energy incineration, even a combination of all three generation methods, have been included as possible options in state-controlled PPC's new business plan.

[18] In February 2020, North Macedonia adopted a ground-breaking new energy strategy, making it the first country in the Western Balkans to name concrete date options for a coal phase-out. Two of the strategy's scenarios entail a coal exit by 2025, with the third delaying closure of the Bitola lignite-fired power plant until 2040. A final decision on which pathway to take will be made in 2021.

[19] Currently, all these SEE countries do not have any coal phase-out plan.

The Paris agreement (2015) marks the latest step in the evolution of the UN climate change regime, which originated in 1992 with the adoption of the United Nations Framework Convention on Climate Change (UNFCCC). The UNFCCC established a long-term objective, general principles, common and differentiated commitments, and a basic governance structure, including an annual Conference of the Parties (COP). The Paris agreement (COP21) is proving to be an important reference point and an accelerator for global energy transformation.

Map 3. 1 **Commitments of European Countries to Phase Out Coal**



Source: Europe Beyond Coal, Financial Times (2)

The main question arising for the countries in SE Europe, including the Western Balkan ones, is whether they are willing to substitute coal with other energy sources. SE Europe as a whole is a carbon-intensive region, with the exception of Albania whose energy sector is remarkably low-carbon, as its system relies almost fully on hydropower for electricity generation. Albania's goal will be to diversify its hydropower-dependent energy mix without increasing CO_2 emissions, while preserving biodiversity. For the rest of the countries in SE Europe, rich in solid fuels, the challenge will be how to diversify their energy mix progressively by minimizing coal use.

An appropriate energy mix appears to be the best vehicle towards achieving decarbonisation. Only through a combination of low-carbon energy sources (i.e. renewables and nuclear), as well as CCS/CCU technology, can this be achieved. However, in a carbon-intensive region such as SE Europe, detailed studies (currently lacking) must be conducted in order to identify the optimum energy mix, taking into consideration the persistent use of coal in the years ahead under a business-as-usual scenario. In order to achieve an optimum energy mix, a detailed strategy for the entire SEE region needs to be worked out, with short-, medium- and long-term targets.

It is only by following such studies that a clear roadmap for SE Europe's transition to a decarbonized state can be established.

Although CCS applications in SE Europe have made little progress, a comprehensive overview of currently available techniques and technologies is needed in order to be able to assess the availability and applicability of the CCS option in the region.

In almost all the SEE countries, local actors are driving the transition while national governments remain committed to coal as a basic energy source and maintain close ties to the coal industry. In Greece, local mayors are looking for alternative ways for the coal-rich region of Western Macedonia to develop, while in Kosovo, protests have taken place in villages affected by the expansion of mining activities. While transition strategies benefit from being driven by local stakeholders, guidance and policy frameworks from the national level are key as they provide stability and enable long-term planning. Among civil society voices, labour unions tend to be vocal opponents of measures that could impact on the coal sector.

The EU has a central role in supporting transition processes. Kosovo, North Macedonia and other countries in the Western Balkans share the aspiration of joining the EU and as part of the Energy Community they are already influenced by the Union's climate and energy policy. The EU sets targets for national climate and energy policies and through its budget has a powerful tool to support the transition away from coal.

Large amounts of indigenous coal and lignite deposits, which provide relatively cheap and easily accessible energy for most countries in the region, are preventing a determined move towards decarbonisation. As shown in the following Table, most countries in SE Europe have well-defined plans and ongoing projects for new coal/lignite-fired power plants. Over the next 8-10 years these plants will add some 10GW of new electricity capacity. Hence, the region's dependence on solid fuels is likely to increase, notwithstanding commitments for increased RES use.

Table 3. 3 **Under Construction and Planned Coal Plants in SEE Countries (MW)*, as of July 2020**

Country	Announced New Plants	Pre-permit	Permitted	Announced + Pre-permit + Permitted	Under Construction	Shelved	Operating	Cancelled (2010-2020)

In Europe, there are initiatives towards a "greener" energy future such as the EU "Coal Regions in Transition Platform", launched in 2017 and included as a non-legislative element of the "Clean energy for all Europeans' package". The platform works as an open forum, gathering all relevant parties, local, regional and national governments, businesses and trade unions, NGOs and academia. It promotes knowledge-sharing and exchanges of experiences between EU coal regions, and represents a unique bottom-up approach to a just transition, enabling regions to identify and respond to their particular contexts and opportunities.

Since 2019, a secretariat has been set up to manage platform activities, covering events, provision of support materials and technical assistance to coal regions, including the Czech Republic, Germany, Poland, Slovakia, Spain and the SE European countries of Greece, Romania and Slovenia. In October 2019, a group of 41 mayors from 10 coal regions in 9 European countries launched a statement supporting a just transition to the post-coal era. (4)

Map 3. 2 **Signatories Declaration of Majors on Just Transition**

Source: WWF

On March 4, 2020, the European Commission adopted the European Climate Law proposal[20], which will enshrine in EU legislation the EU's commitment to achieve net zero GHG emissions by 2050. The 2050 objective reflects commitments under the Paris Agreement and is central to the European Green Deal[21], published in December 2019, which sets out the Commission's commitment to tackling climate change and environmental challenges. To date, most SEE countries have relied heavily on conventional generation technologies. However, over the next decade, countries in this region will have to replace around 50% of their existing capacity for age-related reasons, according to a report by Agora Energiewende (5). However, renewable energy development in SE Europe has been limited until now.

One impediment to scaling up renewables is their higher up-front capital intensity, compared to investment in coal or natural gas. These costs make renewable energy investment more sensitive to political and regulatory conditions than projects with lower up-front capital intensity. And since private investors typically consider ventures in SE Europe riskier than investment in Germany or France, this kind of project in the region faces relatively higher financing and capital costs. The "risk premiums" demanded by investors have a significant effect on the price of renewable power. Past research has shown that higher financing costs could render a wind project in, for instance, Croatia, twice as expensive as the same project with similar resource conditions in Germany. Bloated financing costs thus have two effects: (a) they support the perception that renewables are costly to consumers and taxpayers and (b) they can render renewables incapable of outcompeting fossil-fired generation, even given cheaper system costs. (6)

Policy Inconsistencies Concerning Gas Use in SE Europe

If we take the EC's 2030 energy and climate policies at face value, there is a clear prejudice against any further investment in gas infrastructure in view of its full abandonment over the next 10-15 years and its substitution with hydrogen and RES. Meanwhile, all countries

[20] https://ec.europa.eu/info/files/commission-proposal-regulation-european-climate-law_en
[21] https://ec.europa.eu/info/files/communication-european-green-deal_en

in SE Europe have firm plans encouraging further gas use for power generation, industrial and commercial use and for domestic applications. Almost all governments in SE Europe consider gas as the fastest and most efficient way for decarbonisation, and its increased use is already evident in the region.

Hence, we are witnessing a strong inconsistency in SEE between pursued EU policy targets – with the EIB and EBRD already deciding against new gas infrastructure projects – and locally applied energy policies favouring gas use. Sooner or later, the EU will have to address this serious policy discrepancy and decide on strategy correction and associated medium- and long-term action plans. In other words, to what extent is Brussels willing to prohibit gas use and what alternative fuels is ready to propose?

It is no coincidence that last May, a group of eight EU members from the Balkans and eastern Europe joined forces to defend the "role of natural gas in a climate-neutral Europe" (7). In a joint paper, the group of eight calls for "combined electricity – gas solutions" in the transition to net-zero emissions by 2050. "A transition based solely on renewable energy sources does not consider the need for a diversified energy mix in the EU," says the paper. The paper – titled "The role of natural gas in a climate-neutral Europe" – is signed by a contiguous stack of countries, including south to north, Greece, Bulgaria, Romania, the Czech Republic, Slovakia, Hungary, Poland and Lithuania. It makes the case for gas in the transition away from coal power, which is a dominant form of electricity in many eastern EU member states. "When replacing solid fossil fuels, natural gas and other gaseous fuels such as bio-methane and decarbonised gases can reduce emissions significantly," the paper argues.

In late January 2021, the European Commission asked advisors to rework the EU's green finance taxonomy rules after member states rejected draft implementing guidelines, unhappy about the exclusion of gas as a "transition" activity towards net-zero emissions. (8)

In early February 2021, EU officials announced that the grants and loans provided to EU countries under the bloc's €750 billion Recovery and Resilience Fund will not automatically exclude funding for gas infrastructure as long as these projects are part of a coherent national decarbonisation strategy with clear milestones (9). The European Commission is currently preparing a "guidance document" on how to apply the so-called Do No Significant Harm (DNSH) principle, which applies to the entire Fund. Under that rule, EU money will be prevented from going to polluting technologies. The guidance document will explain "which kinds of conditions can be attached to gas investments" and make them "compatible with that principle".

Among the conditions are assurances that gas is part of a wider transition plan to renewables and guarantees that investments in gas facilities do not create a "lock-in" effect into fossil fuels – for instance, making sure that infrastructure is also suitable for the use of clean gases. All these must be part of a very clear and credible plan for decarbonisation, with clear milestones and deadlines, EU officials stressed. The European Commission reckons that clean electricity will meet 53% of the bloc's energy demand by 2050 as the bloc moves towards reducing emissions to net-zero. That leaves at least 40% for other energy carriers such as gaseous fuels that Brussels says will have to be fully decarbonised in order to reach the EU's stated goal of becoming climate-neutral by 2050. Natural gas has been a major driver of Europe's rapid transition away from coal power and is also proving a baseload back-up for variable renewable electricity generation from wind and solar power.

Discussion

The transition to decarbonised power generation is not an easy regional issue, since in most of the SEE countries electricity generation, which is mainly based on coal and lignite, supports thousands of jobs while it forms the basis of an extensive industrial base. Although all countries in the region to a greater or smaller extent are committed to RES and energy efficiency programmes and specific targets, they are also pursuing a parallel carbonisation agenda as several coal-fired power plants are under construction or at an advanced planning stage. In short, coal-based power generation is also moving ahead, adding substantial capacity from now until 2025 (1.5 GW per year for SEE and 2.5 GW for Turkey, i.e. total 4 GW per year over the next 7-8 years). New RES capacity over the last three-year period is less than 500 MW per year of installed capacity excluding Turkey, and approximately 1.5 GW per year including Turkey. As a result, there is a substantial gap between new coal-fired power plants and anticipated RES installations.

In addition to this RES supply gap, we must consider the likehood of a power generation shortfall as early as 2027. If that happens, the region will be transformed from an exporter of electricity to a net importer. This will drive up electricity prices. Underinvestment today and higher electricity prices in the near future will act as a brake to economic growth, fulfilling lacklustre performance forecasts for the region.

The road to decarbonisation can be approached on two levels: (a) through policy addressing the energy mix and assesseing the optimum rate of decarbonisation and investment in economic terms; and (b) through technology, whose penetration depends on the policies to be implemented and could contribute significantly towards decarbonisation. Good examples are the use of CCS/CCU or dual-fuel power plants, analysed by IENE in its "SE Europe Energy Outlook 2016-2017" study. (10)

The arduous and complex decarbonisation process in SEE is further burdened by a strong coal/lignite legacy and serious energy security issues. Rapidly increasing carbon prices and stricter EU regulations on air-polluters will bankrupt outdated lignite-fired power plants in the region over the next decade, making them politically untenable. Rising carbon prices will require ever bigger state subsidies for power plants, which is clearly not sustainable. Without these subsidies, fossil-based generation will make no economic sense.

Key Regional Energy Issues

Key Regional Energy Issues

Before looking at SE Europe's core 15 countries (Chapter 5) and peripheral ones (Chapter 6), and before moving ahead to analyse the different energy sectors (Chapters 9-12), it is important to consider the big picture and become acquainted with the key issues which confront the region's energy sector.

These include the relatively high dependence of the majority of the countries on solid fuels, mostly used for power generation, high dependence on imported oil and gas, lack of adequate gas supply routes and interconnections (especially relevant for the main Balkan block), slow penetration of renewables and slow progress on energy efficiency improvement. Some of the inadequacies have clear geopolitical bearings, as we shall see.

The slow differentiation of the regional energy mix, which in spite of the rise of RES and gas penetration remains bound to high solid fuel consumption and sizeable oil imports, is no doubt a prime point of reference. The large amounts of indigenous coal and lignite deposits provide relatively cheap and easily accessible energy supplies for most countries of the region and hence are seen as preventing a determined move, by the European Commission and certain governments, towards decarbonisation. Hence, we have here a major policy challenge, which governments and the EC will have to address. Simply put, there is a huge incompatibility between stated and adopted EU goals for decarbonisation and the region's silent commitment to continuing large-scale solid fuel use.

Although several countries in the region appear determined to exhaust its coal/lignite deposits, they are in parallel developing renewables and other carbon free resources such as nuclear power. Given the financial and legal constraints in most countries, the rise of Renewable Energy Sources (RES), especially for electricity generation, over the last five years appears impressive. Yet because of the intermittent nature of power generation from RES and undeveloped large-scale energy storage, their contribution into the electricity production of the different countries appears limited. However, given the strong market dynamics of the RES sector, the introduction of viable large-scale storage schemes in the mid-term and hydrogen in the long-term are distinct options in the years ahead.

High oil and gas import reliance for most SEE countries stood at 87.50% on average for oil and petroleum products and at 80.28% on average for gas, on the strength of 2019 figures, with some countries reaching 100% dependence in both categories. This represents a small departure from the situation reported in IENE's 2017 "SEE Energy Outlook"[1]. Such high energy dependence is way above that of the EU-27, which on average stood at 58.2%. This means the state finances of several SE European countries are servient to the vagaries of international oil prices, as we have clearly seen in the period of 2010-2014, when the oil and gas import bill of most SE European countries ballooned to unprecedented levels, thus siphoning off much needed funds in order to meet basic transportation, heating and industry requirements. In other words, the then-prevailing high oil and gas prices prevented governments from channeling funds to development and social welfare projects, while condemning economic growth to zero or, in the best of cases, anemic rates. In view of oil price behavior in the H1 of 2021, with Brent oil above $70 per barrel, we might experience a similar situation in 2021/2022.

Another important regional issue concerns oil and gas exploration efforts and plans for future production. Most countries in SE Europe, in view of their great dependence on oil and gas imports, have over the years harbored plans and initiated long-term programmes aiming at the exploitation of their indigenous hydrocarbon potential (see Chapter 8). Now, in many cases,

[1] IENE (2017), "SEE Energy Outlook 2017", https://www.iene.gr/articlefiles/seeeo%202016-2017_iea%20paris.pdf

such plans have been seriously challenged following the double blow of the coronavirus (COVID-19) and the sharp fall of international oil prices in 2020 and the charge of EU's green policies.

On the one hand, the gloomy atmosphere in the global oil market, following NGOs' persistent calls for an end to hydrocarbon exploration activities and the rising geopolitical tensions present in the East Mediterranean have caused concern to international oil companies active in SE Europe. Questions arise about the viability of the companies that currently hold licensing blocks in the region, but also about the competitiveness of natural gas in an era of low prices (especially for LNG) and growing enmity against hydrocarbons in view of their implied negative environmental footprint.

In addition, natural gas, which is the fossil fuel with the lowest emissions, is facing another serious challenge by the narrow-confines of the EU Taxonomy (see Chapter 3). Hence, the decarbonization of the SE European region, without the use of natural gas, becomes an impossible equation thanks to EU's bureaucratic thinking, which appears to be completely cut-off from the harsh economic reality in the field in several SE European countries.

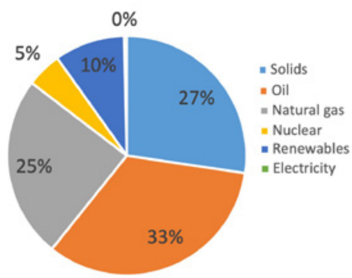
Other key challenges of the energy sector include the lack of adequate gas interconnections, which are preventing regional market development, since available gas quantities cannot be easily transported from one well supplied geographic area to another needy one. To a lesser extent, the region is in need of more and better electricity interconnections, something which is especially visible in island regions, such as Greece and Cyprus. Advancing international electricity interconnections especially between Italy and Western Balkans and between mainland Greece and the Israel-Cyprus-Crete axis is becoming a priority in view of the fast advancing electricity market integration in the region.

Since the publication of the last "SEE Energy Outlook" study in 2017, electricity markets in the region have progressed impressively with EU's Target Model now in place in most countries and markets coupled across the region. A detailed account of electricity markets is presented in Chapter 10.

4.1 The Glacial Change in the Region's Energy Mix

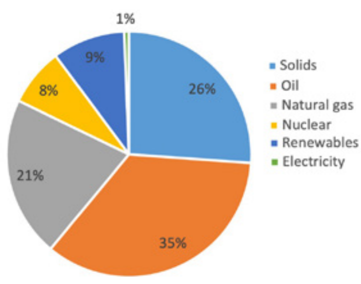
A key observation regarding the region's energy situation is related to its energy mix, taking into account all 14 countries (i.e. EU Member States, WB6 and Turkey). SE Europe's energy mix, with and without Turkey, is changing, albeit very slowly. In summary, between 2009 and 2019 (see Figures 4.1-4. 4) there is lower use of coal (lignite), gas and nuclear, more RES and almost the same level of oil, given the different total gross inland consumption. In a sense, this is disappointing given the huge emphasis placed over the past years on RES and the lowering of oil use.

Figure 4.1 **Gross Inland Consumption (%) in SE Europe, including Turkey, 2009 (Total=263.6 Mtoe)**



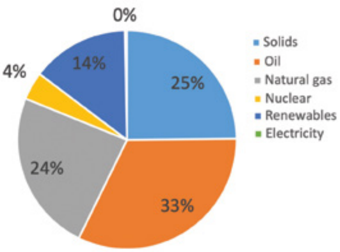
Source:Eurostat, IENE

Figure 4.2 **Gross Inland Consumption (%) in SE Europe, without Turkey, 2009 (Total=164.2 Mtoe)**



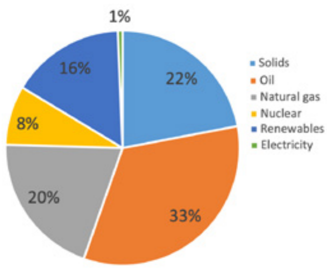
Source:Eurostat, IENE

Figure 4.3 **Gross Inland Consumption (%) in SE Europe, including Turkey, 2019 (Total=299.5 Mtoe)**



Source:Eurostat, IENE

Figure 4.4 **Gross Inland Consumption (%) in SE Europe, without Turkey, 2019 (Total=152.2 Mtoe)**



Source:Eurostat, IENE

Examining closer the regional energy mix between 2009 and 2019, a number of useful observations can be made:

(a) Over the last 10-year period, only a minor differentiation of the region's energy mix has taken place, both in the case where this includes Turkey and in the other that it does not.

(b) The most noticeable change is the increased contribution of renewables in both cases.

(c) The contribution of gas, although higher in both cases, remains marginal.

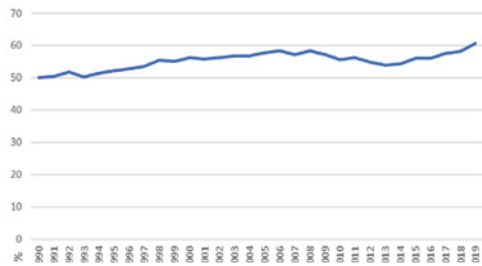
(d) There is clearly less use of solid fuels in both cases, but the retreat is not as big as anticipated so as to advance EU's decarbonisation agenda.

(e) Oil has an almost constant contribution to the overall energy mix as it covers almost 100% of transportation needs in all countries.

4.2 High Energy Import Dependence

In 2019, the energy dependence[2] of the EU-27 stood at 60.7%, the highest over the last decade. As illustrated in Figure 4.5, the evolution of EU-27 energy dependence has not been constant over 1990-2019; however, it has continuously stood above 50% since 1990.

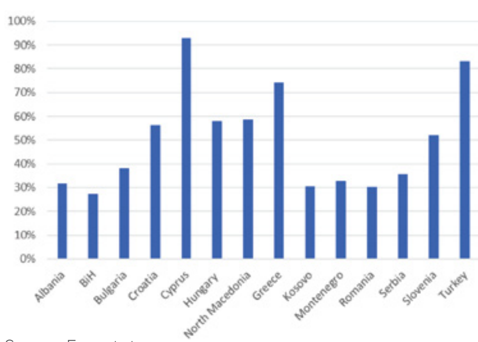
Figure 4.5 **Evolution of the EU Energy Dependence (%) over 1990-2019**



Source:Eurostat

Regarding SEE countries, energy dependence also varies significantly and averaged at 50.10% in 2019, taking into account the countries shown in Figure 4. 6. These figures are issued by Eurostat, along with the publication of the detailed 2019 annual results on energy supply, transformation and consumption in the EU.

Figure 4.6 **Energy Dependence (%) in SE Europe (2019)**

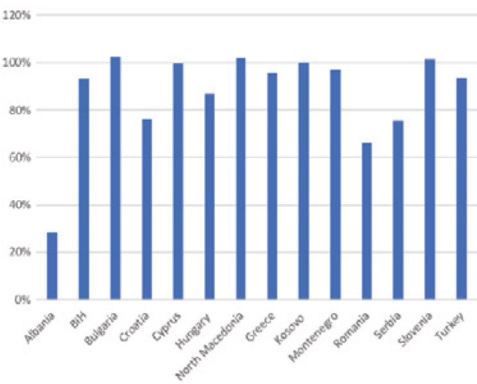


Source:Eurostat

2 The energy dependency rate shows the extent to which an economy relies upon imports in order to meet its energy needs. It is defined as net energy imports divided by gross inland energy consumption (which includes stock changes) plus fuel supplied to international maritime bunkers, expressed as percentage. A negative dependency rate indicates a net exporter of energy, while a dependency rate in excess of 100% relates to the build-up of stocks (Eurostat).

Eurostat also presents data for total oil and petroleum products, gas and solid fuels use separately for the SEE region in 2019. More specifically, almost all SEE countries (excluding Albania) relied more than 60% on oil and petroleum products imports in 2019, while Albania's dependence on total oil and petroleum products was about 28.3% (see Figure 4.7).

Figure 4.7 **Total Oil and Petroleum Products Dependence (%) in SE Europe (2019)**

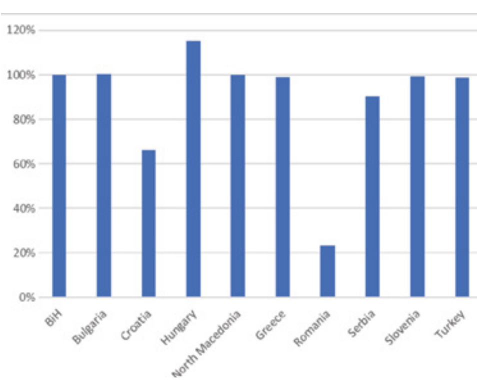


Notes: A dependency rate in excess of 100% relates to the build-up of stocks.

Source:Eurostat

Regarding gas, the majority of the SEE countries (excluding Romania) depended more than 60% on gas imports in 2019, while the gas dependence of Romania was about 23.3% (see Figure 4.8).

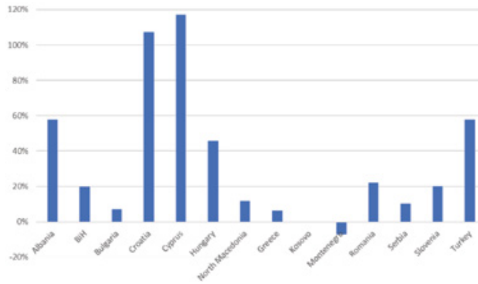
Figure 4.8 **Gas Dependence (%) in SE Europe (2019)**



Note: Albania, Kosovo, Cyprus and Montenegro do not import natural gas.
Source: Eurostat

In terms of solid fuels, only four SEE countries (i.e. Albania, Croatia, Cyprus and Turkey) depended more than 50% on solid fuel imports in 2019, while the solid fuel dependence of the remaining countries was lower than 50% (see Figure 4.9).

Figure 4.9 **Solid Fuels Dependence (%) in SE Europe (2019)**



Note: A negative dependency rate indicates a net exporter of energy. Source: Eurostat

Despite the fact that most of the SEE countries are highly dependent on oil and gas, which are widely used in the transport and household sectors, regional energy dependence is low, as the remaining energy used derives from hydropower and biomass, which are indigenous.

4.3 The Decarbonisation Challenge

As the EU moves towards committing to the decarbonisation of its economy to net-zero greenhouse gas (GHG) emissions by 2050, the SE European EU member states are still struggling with dysfunctional energy markets, blatantly inadequate long-term planning capabilities and an overwhelming dependence on fossil fuels. Combined, these factors represent significant impediments to decarbonisation objectives. The successful transition towards a low-carbon future in the EU relies on the resolution of these problems and the acknowledgement of the different starting points of the SEE EU member states in the decarbonisation process.

With the 'Clean energy for all Europeans' package[3], the Regulation on the Governance of

[3] https://ec.europa.eu/energy/topics/energy-strategy/clean-energy-all-europeans_en

the Energy Union introduced a new cooperation framework between member states and the European Commission, which requires rigorous and standardised national energy and climate planning. A novelty of this package is that binding targets will only be set at the EU level. Under this new mechanism, each member state is required to produce an integrated National Energy and Climate Plan (NECP) for 2021-2030, which will be updated once by 30 June 2024. Member states must also release progress reports, with the first one due in 2023. The plans must be written in a binding template in which governments must outline the actions and strategies to be pursued for each dimension of the Energy Union. Member states will also be obliged to consider the long-term 2050 perspective.

The long-term strategies should be revised every five years and updated every ten years. This framework provides both opportunities and challenges for all SEE countries. While the absence of binding national targets means that the new governance framework represents a 'softer' mechanism, it is not any less robust. The NECPs depend on national initiative and management of commitments, which can provide the needed flexibility for tailoring individual solutions. Moreover, by providing a binding template, the governance framework can trigger the development of rigorous national energy and climate planning, which has often been lacking in SE Europe.

At the same time, however, this new system may also lead to tensions between SE Europe, generally reluctant to take on aggressive decarbonisation, and the Northern and Western member states. If SE European countries perceive their energy systems and security of supply to be vulnerable, they are likely to adopt very defensive positions at the EU level to maintain strict control over their national energy mixes. This can lead to insufficiently ambitious NECPs, which may prove difficult to correct at a later stage. Hence, if the governance framework is to deliver on its objectives, the concerns of SEE member states cannot be ignored.

While more than half of the electricity generation capacity in SE Europe currently relies on thermal coal and lignite, a power system with a much higher deployment of renewable energy sources – as high as 50% by 2030 – has been shown to be realistic (1). This will require drastic changes in the status quo. While the need for strategic planning is evident, the energy transition will also rely on a mix of rigorous and ambitious policy design, access to diverse financial instruments for investments, as well as functional and transparent energy markets, accompanied by effective social protection for vulnerable energy consumers. Under these circumstances, one condition for a successful decarbonisation of the European economy is to understand the particularities of the EU member states in the SEE region as well as the Western Balkan countries in order to address specific problems with targeted policy and financial interventions. This requires increased attention and cooperation from both EU institutions and other member states.

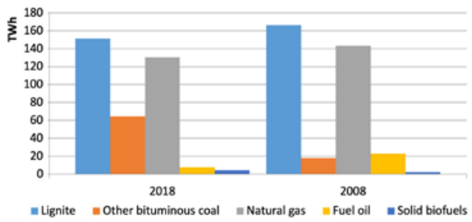
4.4 The Role of Gas

Based on data from ENTSO-e (2), gas-fired power generation in the EU was up by 6% in the fourth quarter of 2019, compared to the same period of 2018. In absolute terms, electricity generated from gas increased by 9.5 TWh on an annual basis. Gas-fired generation remained strong in Q4 2019; however, given the strong output in the first three quarters of the year, it showed less seasonality in 2019 than in earlier years. In Q4 2019, gas wholesale prices picked up in Europe, slowing down the increase in gas in the electricity sector. In 2019 as a whole, gas fired generation in the EU increased by 88 TWh (by 15%), and it represented 23% of the total EU power generation, up from 19.6% in 2018. (3)

At the same time, coal- and lignite-fired generation decreased by 25% in the EU, and its share fell to 14% in 2019 from 18.6% in 2018. Meanwhile, solar and wind generation was up, implying that gas and renewables kept on replacing solid fuels in the European electricity generation mix. Although carbon prices decreased slightly in Q4 2019, reaching almost €25/tCO_2e on average, the competitiveness of gas-fired electricity generation did not deteriorate measurably vis-à-vis coal, as electricity generation from gas is half as carbon intensive as that from coal.

In SE Europe, the majority of the gas and coal/lignite produced was used for gross power generation and as a source of heat for industry and buildings in 2018, as shown in Figure 4.10. During 2008-2018, we observe a parallel decrease of lignite and natural gas use on SE Europe's gross electricity generation.

Figure 4.10 **Gross Electricity Generation (TWh) by Type of Plant in SE Europe (2008 and 2018)**



Source: Eurostat

However, the future of natural gas seems ominous. The European Investment Bank (EIB) adopted new energy lending policies on November 14, 2019 (4), which aim at, among other things, gradually phasing out support for oil and natural gas production, gas infrastructure (networks, storage, refining facilities), and power generation technologies resulting in GHG emissions above 250g of CO_2 per kWh of electricity generated.

The EIB will continue to approve projects already under appraisal until the end of 2021. In addition, during this period, the Bank can approve gas infrastructure projects included under the 4th List of Projects of Common Interest (PCI) co-financed with the EU budget, which are deemed important to the European security of gas supply[4]. More information about policy inconsistencies concerning gas use in SE Europe to be found in Chapter 3.

4.5 The Role of Nuclear Power

In SE Europe, there are five countries (Bulgaria, Hungary, Romania, Slovenia and Croatia) that currently operate nuclear power plants (NPPs), while Turkey is expected to build no fewer than 3 NPPs over the next decade. Nuclear power, although it covered only 4.0% of the gross inland consumption in SE Europe in 2018, remains a viable option for growth because it offers important baseload capacity and supports the EU's decarbonization policies. The zero emissions from operating NPPs contribute to the region's efforts to curtail GHG emissions. This means that nuclear energy has an important role to play in the SE European energy and electricity mix over the next decades.

Following the tragic accident at Fukushima's NPP in March 2011 and operational security reviews, which have since been conducted by the SEE countries that host NPPs, the use of nuclear power in the region is unlikely to diminish over the next decade. Neither Bulgaria nor Romania nor Hungary are likely to shut down the Cernavoda, Kozloduy 5-6 and Paks 1, 2, 3, and 4 power plants respectively on account of safety concerns.

The same applies for Croatia and Slovenia, which, between them, share the Krško NPP. Both governments are very well aware of the fact that a decrease in the participation of nuclear power in their electricity generated portfolio cannot be easily replaced by renewables or be compensated by an increase of coal generated electricity due to the equally burdensome environmental costs. If they are to reduce the participation of nuclear power in their total electricity mix, both states have as an alternative the increase of imported gas, magnifying their already high dependence on gas.

[4] On February 12, 2020, the European Parliament adopted the 4th list of PCIs, including 32 gas, 6 oil and 5 CO_2 network projects: https://bernardenergy.com/lastestdevelopments/ep-adopts-fourth-list-projects-common-interest/

Theoretically, the participation of nuclear generation in the regional electricity mix is set to diminish significantly as the rising demand of Bulgaria and Romania will be covered by increased volumes of natural gas and, to a lesser extent, renewables. However, this might change as both Romania and Turkey are definitely going ahead with plans to increase their nuclear installed capacity, which will result in two major nuclear power generation complexes with 6 GW of new installed capacity to be operated by 2030.

In the cases of Bulgaria (Units 5 and 6 and the planned Unit 7 of Kozloduy NPP) and Turkey (the Akkuyu site), Russia might have a role to play. However, it should be recalled that strategic investments have two substantial characteristics in the energy sector. They need many years to be implemented but they last for decades. Such long-term planning should not be subverted by short-term political priorities against regional, economic and safety considerations.

In this sense, the Fukushima anti-nuclear rationale does not appear to hold in the case of SE Europe. For countries already involved in nuclear power development (i.e. Bulgaria, Romania, Hungary, Croatia/Slovenia, Turkey), the road ahead is unlikely to be obstructed by revised risk assessments.

Developing further nuclear power generation in the region will be a real challenge as not all countries favour this option. Detailed studies need to be undertaken to identify the real potential pitfalls of nuclear energy and to assess the compatibility of nuclear and RES power in the context of decarbonization.

According to a leaked document, as cited by Euractiv (5), experts tasked with assessing whether the European Union should label nuclear power as a green investment will say that the fuel qualifies as sustainable. The European Commission is attempting to complete its sustainable finance taxonomy, which will decide which economic activities can be labeled as a sustainable investment in the EU, based on whether they meet strict environmental criteria. EU experts last year were split over whether nuclear power deserved a green label, recognising that while it produces very low CO_2 emissions, more analysis was needed on the environmental impact of radioactive waste disposal.

According to Reuters (6), the European Commission asked the Joint Research Centre (JRC), its scientific expert arm, to report on the issue. A draft of the JRC report said that nuclear power deserves a green label. "The analyses did not reveal any science-based evidence that nuclear energy does more harm to human health or to the environment than other electricity production technologies", it said. Storage of nuclear waste in deep geologic formations is deemed "appropriate and safe", it said, citing countries including France and Finland in the advanced stages of developing such sites.

Two expert committees will scrutinize the JRC's findings for three months before the European Commission takes a final decision. EU countries are split over nuclear power. France, Hungary and five other countries in March 2021 urged the Commission to support it, while other states oppose it.

4.6 RES as a Key Supply Source

SE Europe's RES potential

Better interconnections, a higher share of RES and better energy efficiency, are some ways to address SE Europe's energy dependence. In terms of RES, SE Europe has abundant resources, and their use is already part of many people's daily lives. Thanks to considerable installed hydropower capacity and the extensive use of biomass for residential heating, the SEE economies use a higher proportion of RES than the EU average (7). n fact, despite having an installed hydropower capacity of more than 22 GW, the SEE region still has the largest remaining unexploited hydropower potential in Europe, as its river catchments have remained largely undeveloped. The technical potential of hydropower is estimated to be 522 PJ per year, as shown in Table 4.1.

While up to 140 large (above 10 MW capacity) greenfield hydropower plants and more than 2,700 small projects (below 10 MW capacity) are in the production pipeline, the sustainability of these projects has sometimes been questioned. In the last couple of years, opposition to the construction of small hydropower plants has been growing, mainly in Albania, Bosnia and Herzegovina, Croatia and Serbia. Local stakeholders and non-governmental organisations (NGOs) have called for a set of principles for sustainable hydropower to be respected, with one of these principles being the prioritisation of investment in rehabilitating existing plants.

Table 4.1 **Technical Potential for Utility-scale Solar PV, Wind and Hydropower in the Electricity Sector in SE Europe (TJ)**

	Utility-scale solar PV	Onshore wind	Hydropower
Albania	13 342	49 154	56 059
Bosnia and Herzegovina	14 886	94 810	88 193
Bulgaria	36 468	190 264	48 071
Croatia	15 682	104 951	30 600
Kosovo*	3 006	13 860	4 853
Montenegro	3 874	23 332	18 079

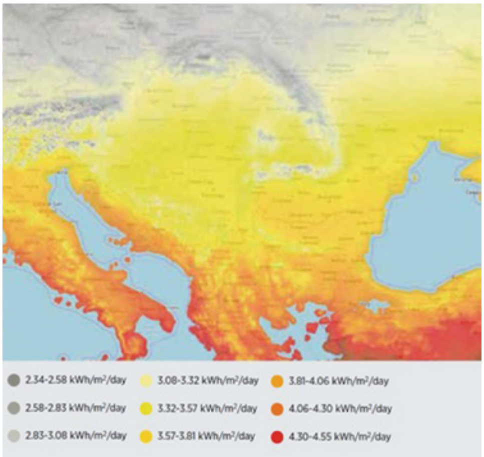
Romania	92 902	554 522	136 800
Serbia	33 509	188 590	64 800
Slovenia	1 613	8 266	58 539
SEE	245 052	1 436 156	532 515

TJ = Terajoule

Source: IRENA

Global horizontal irradiance, a key parameter in solar PV installation, is higher in the southern part of the region, where it reaches over 4.5 kWh per square metre per day (kWh/m2/day). Solar resources in the northern part are more modest, down to 3 kWh/m^2/day, but in line with or better than other European countries with large PV deployment, such as Germany (see Map 4.1). The utility-scale solar technical potential of the SEE region is estimated at around 245 PJ (see Table 4.1).

Map 4.1 **Solar Resources in the SEE Region and Surrounding Countries**

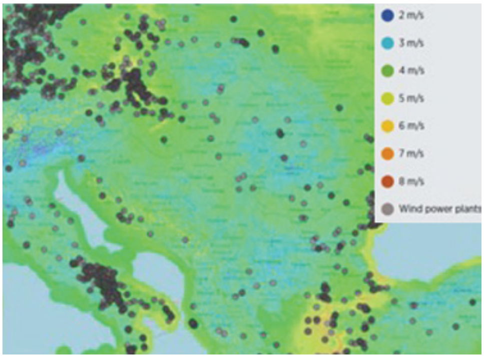


Source: IRENA

The whole region is endowed with good wind resources, with wind blowing at average speeds of between 5.5 metres per second (m/s), and 7 m/s at 100 metre height. The mountainous and coastal landscape increases the variation in wind resources across the region, with higher average wind speeds in coastal areas and at high altitudes. The Eastern coast of the region (i.e. Romania) enjoys the best wind, with average speeds of 6-to-7 m/s (see Map 4.2).

The Adriatic coast (i.e. Albania, Bosnia and Herzegovina, Croatia, Montenegro and Slovenia) enjoys similar average wind speeds, but this area is also regularly hit by winds that gust between 150 and 200 kilometres per hour. This puts additional stress on wind turbines. However, wind energy is not harvested at its full potential, as in nearby countries with similar wind resources, with the exception of the EU member states of the region. The technical potential of SEE's wind energy is currently estimated at 1,436 PJ (see Table 4.1). Notably, the presence of a good technical potential is a necessary but not sufficient condition for deployment. Other aspects to consider are the economic limits to supply, market constraints and the presence of appropriate supply chains.

Map 4.2 **Wind Speed and Wind Power Plants in the SEE Region and Surrounding Countries**



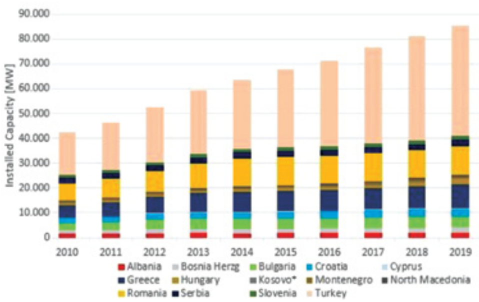
Source: IRENA

RES Increased their Share in SE Europe's Electricity Mix

The total installed RES capacity in SE Europe doubled during the past decade, with local systems exceeding 85.56 GW of installed capacity in 2019, according to IENE. This represents an increase of 100.5% since 2010, when the region counted 42.68 GW of installed RES units. In addition, the power generation from RES, including hydro, stood at 199.2 TWh in 2018. This corresponds to a 40% increase over the last decade.

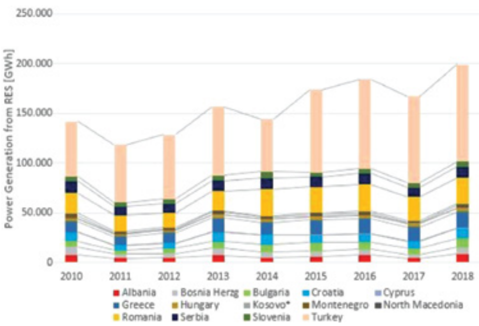
It should be noted that electricity generation from RES in the SEE region is heavily affected by the hydrologic cycle, which has shown signs of heavy volatility throughout the decade. Most notably the region was affected by drought especially during 2011, 2014 and 2017, when it halted the increase of y-y generation from RES, despite the increased deployment of other RES systems, mainly wind and solar. The most affected countries by the hydrologic cycle were Turkey, Croatia, Albania and Bosnia and Herzegovina. The most widely deployed renewables are by far in Turkey, which has an RES fleet, which consists mostly of hydro and wind, with a considerable capacity of geothermal energy. In 2020, Turkey's total installed RES capacity exceeded 44.5 GW. Turkey is followed by Romania and Greece, with installed RES capacity of 11.2 GW and 9.8 GW respectively.

Figure 4.11 **Total Installed RES Capacity (MW) by Country in SE Europe (2010-2019)**



Source: IRENA

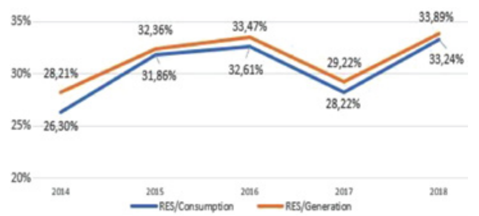
Figure 4.12 **Power Generation (GWh) from RES, Including Hydro, in SE Europe (2010-2019)**



Source: IRENA

Moreover, RES units have increased their regional share in power generation to 33.89% in 2019, i.e. by more than 5.5 percentage points compared to 2014, when they contributed 28.2%. In addition, in 2019, the share of RES in total regional electricity consumption rose to 33.2% from 26.3% in 2014.

Figure 4.13 **Share (%) of RES in Total Regional Consumption and Regional Power Generation in SE Europe (2014-2019)**



Sources: IRENA, ENTSOe, ERE, IENE

As RES have already been recognized as one of the most important resources in mitigating climate change, the global market is amidst an ongoing ramping up of RES installations. Falling production costs of variable renewables systems have fallen rapidly during the past decade, driving an escalation in the deployment of competitive solar PV and wind turbines across the region. The deployment of variable renewables is more evident in more mature markets, such as Turkey and Greece, which have increased their RES penetration impressively, marking annual increases in their installed RES capacity by 5.6% and 8.7% in 2019 respectively.

4.7 Energy Efficiency as a Champion Energy Source

On October 10, 2020, the European Commission adopted "An Economic and Investment Plan for the Western Balkans" (8), which identified flagship initiatives related to clean energy and the transition from coal. An overall budget of €9 billion during 2021-2027 is proposed for the Plan's implementation, of which a fair share is expected to finance building renovation and decarbonisation of the heating and cooling sectors.

The Plan relies on support from the Energy Community Secretariat to implement the Renovation Wave. In this respect, its role may be manifold. The Secretariat offers its assistance to the Western Balkan Contracting Parties in improving the legal framework and removing regulatory barriers in the building sector; facilitating information sharing and exchanging best practices; and serving as a bridge between the providers of technical and financial assistance and beneficiaries.

In contrast to the Western Balkan countries, the EU has already acquired extensive experience in implementing financial and fiscal instruments to support building renovations. These instruments have different sources of finance, delivery mechanisms and approaches, and are available to more sectors, including residential, commercial and Small and Medium sized Enterprises (SMEs). In the EU, only in the last four years, the Joint Research Centre[5] identified a total of 129 ongoing public financial and fiscal schemes supporting energy renovations, of which around 61% are in the form of grants and subsidies, 19% are soft loans, 10% are tax incentives and the remaining 10% a combination of the above. The same study showed that around €15 billion are being spent annually across the EU for energy efficiency in public and non-public buildings. The majority of the instruments applied in the residential sector in the EU Member States are based on grants and subsidies, traditional loans and soft loans and fiscal incentives.

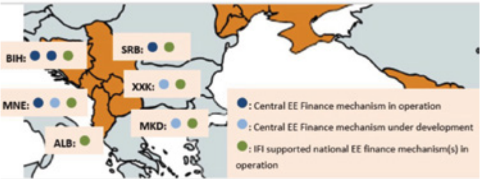
Despite the many instruments at hand, the renovation of buildings in the EU has proved to be very difficult and quite slow, compared to expectations. Presently only 1% of buildings undergo energy efficient renovation every year, while about 75% of the building stock is considered energy-inefficient. In the Energy Community, the renovation process is even less advanced.

In the Western Balkans, it is estimated that approximately €1.06 billion were invested in energy efficiency projects in all building categories between 2010 and 2020, based on Energy Community Secretariat calculations (9). The figure is significantly lower in the residential sector, which due to the many barriers is considered a difficult market to serve as it is fragmented, with small-scale investments, and riskier than the other building categories.

With the support of donor engagement in energy efficiency projects, many Western Balkan countries have established, or are in the process of establishing, centralised energy efficiency financing mechanisms. These are complemented by multi-country initiatives supported by International Financial Institutions (IFIs), as shown in Map 4.3.

[5] Joint Research Centre (2019), "Accelerating energy renovation investments in buildings – Financial and fiscal instruments across Europe", https://ec.europa.eu/jrc/en/publication/eur-scientific-and-technical-research-reports/accelerating-energy-renovation-investments-buildings

Map 4.3 **Overview of Centralised Energy Efficiency Financing Mechanisms in the Western Balkans**



Sources: Energy Community Secretariat

One category is represented by multi beneficiary programmes, mostly funded by loans from IFIs with incentives and technical support provided by the European Union. However, despite the large number of regional energy efficiency credit lines (supported by IFIs and the EU) available to help improve energy efficiency in residential buildings in the Western Balkans, their uptake has remained modest and focused on high income segments and those living in detached houses.

The building sector accounts for over 40% of total energy consumption in the Western Balkans. Renovating public and private buildings to meet minimal energy performance standards can make a very significant contribution to the reduction of GHG emissions, improve living standards and health. A building Renovation Wave implemented with the help of the Energy Community will assist the Western Balkans and SE Europe in general in decarbonizing public and private building stock, with a strong emphasis on digitalisation and taking into account energy poverty. The EU, together with international financing institutions, will support the efforts of the Western Balkans partners to triple the current renovation rate and energy savings in existing buildings and achieving nearly-zero energy and emission standard in new buildings.

4.8 Energy Market Liberalization and Integration in SE Europe

Ever since the EU set up the process of developing the internal market, the energy sector and especially the electricity sector have monopolised the EC's attention. It has taken more than 20 years of persistent efforts and countless disagreements and legal cases with incumbent electricity authorities for the European Commission to manage the transition from state control of the electricity sector to an open and market-oriented system with competition among producers, suppliers and distributors. In SE Europe, this liberalisation process was fraught with difficulties and numerous non-technical obstacles, as the incumbent companies in almost all countries solidly resisting change in order to maintain market control and hence political influence.
Several years later, the situation in EU member countries and Turkey looks very different, with certain countries having managed to complete what appeared to be an anomalous transition period. In the case of Turkey, the progress achieved in electricity market unbundling and retail competition has been highly successful, with the market opening up much faster than anticipated. In the case of the Western Balkans, we have the intervention of an EU institution, the Energy Community, through the contracting parties, which has facilitated the overall transition process and acceptance of the European Acquis. Hence, some solid steps have been made towards electricity market competition. However, progress is not very satisfactory in most contracting parties, largely because of the inflexible market structure and the stiff hold of the state over market mechanisms.

Due to the increasing significance of having a secure electricity supply and its positive impact on the environment and society, the energy sector in SE Europe is characterized by vertically integrated natural monopolies. If one also takes into account that the energy sector has long been highly regulated, it is easy to see why electricity and gas markets have high operating costs and high retail prices, along with costly large-scale investments, low-quality services and lack of competition in supply and generation.

Reforms in several countries in SEE have already been implemented in order to generate electricity within actual marginal production costs. However, distribution and transmission services are expected to remain natural monopolies as they satisfy security of supply.

Furthermore, there is a kind of dilemma between bilateral trading and power exchange-based markets in terms of competition. Despite the fact that bilateral markets are more flexible than the exchanges, their negotiation procedure can be expensive, while exchanges provide higher security for market participants, lower trading costs, increased competition and full transparency. As the number of players in the electricity market of each country in SEE region increases, the higher the competition becomes. Several countries have already established an energy market and enjoy its benefits.

Indicatively, in the electricity sector of Bosnia and Herzegovina, there is no competition and no electricity trading platform, Albania and Kosovo have already signed an agreement to establish a joint power exchange, known as APEX, while competition in the Croatian market is very limited as it trades bilaterally. In Montenegro, the wholesale market is open for competition, including the balancing market, except for the balancing reserve.

In general, the SE European electricity markets can be characterized by the following issues: (a) only basic steps in the electricity market procedures were realized by the majority of the countries, (b) cross-border power trading has until now been based on bilateral agreements between countries, (c) market coupling especially via the flow-based approach has not yet been fully implemented, and (d) the transmission network in the SEE region seems to have different characteristics in comparison with the Central and Western European meshed grid, where market coupling procedures are more mature. The main challenge for the economies of SE Europe is to commit to and insist on the implementation of long-term reforms that will target competitiveness and better integration among the EU member states of the region, their neighbors, candidate countries and potential candidate countries. Such reforms in the economy are likely to have a direct and positive impact on the further development of energy markets and the creation of favourable conditions in attracting suitable outside investment.

In this edition of "SE Europe Energy Outlook", we have placed equal emphasis on gas market liberalisation since gas, supported through a number of policy measures related to the EU's climate change targets, is poised to penetrate further into the energy mix of most countries, despite some recent policy measures against it. Where do we stand on deregulation and how far are the various national markets are opening up to competition?

The real progress achieved in the gas markets of SE Europe during the last decade is rather poor. The nature of gas markets in the region remains predominantly national, with very little, if any, cross border trade taking place, other than that implemented through the long term supply agreements national incumbents have with their traditional suppliers.

With the exception of Croatia and Romania, whose indigenous production covers almost 60% and 80% of their domestic demand respectively, all other SEE countries that have a gas market are solely depending on Russian imports. Albania, Montenegro, Kosovo and Cyprus still have no gas market, while only Greece, Croatia and Turkey possess LNG gasification terminals, representing the only LNG import points in the whole region.

In addition, the whole region is characterized by the lack of sufficient interconnectors, which would allow the development of gas trade between the countries. In practice, the only pipelines that link the countries of the region are the traditional transit pipelines, which have been developed to serve the long-term contracts signed several decades ago, mainly in implementation of Intergovernmental Agreements (IGAs). In most of the cases, these pipelines are subject to long-term capacity reservation through ship-or-pay transit contracts. The validity of all those transit agreements, concluded before countries such as Romania and Bulgaria joined the EU, supersedes the legal obligations arising from the European Acquis on energy. Therefore, access to these pipelines is, in principle, prohibited until the Intergovernmental Agreements expire.

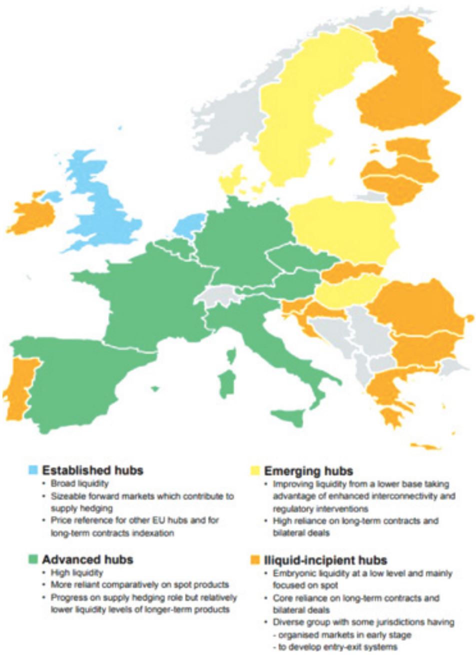
Over the last two years, the only important gas infrastructure developments in SE Europe included the operation of the Turkish Stream pipeline and TAP. Turkish Stream connects Russia with Turkey across the Black Sea. On January 18, 2020, the opening ceremony was held, marking the first deliveries of gas to Turkey. On January 27, 2020, 1 bcm of natural gas was delivered via the pipeline.

In addition, according to an announcement by Bulgartransgaz, Russian gas for Bulgaria, Greece and North Macedonia is now delivered via Turkish Stream, which crosses the Bulgaria - Turkey border. In practice, this means that as of early January 2020 Gazprom, by delivering gas via the Turkish Stream pipeline, has fully replaced the route that passed through Ukraine and Romania via the Soviet-era Trans-Balkan Pipeline.

The Trans-Adriatic Pipeline (TAP), forms part of the Southern Gas Corridor, which transports natural gas to Europe from the Shah Deniz II field in Azerbaijan. Commercial operation began on November 15, 2020. TAP AG, its builder, owner and operator, confirmed the commencement of gas flows from Azerbaijan on December 31, 2020. The first gas volumes reached Greece and Bulgaria via the Nea Mesimvria interconnection point with Greece's DESFA, as well as Italy, via the Melendugno interconnection point with Italy's SNAM Rete Gas.

As it is evident from the above analysis and Map 4.4, we are still facing a highly fragmented landscape for gas market development in SE Europe, with effectively no cross border trading as yet, which is very difficult to support the development of competition and of liquid market trading, despite the high interest of several SEE countries in becoming gas trading hubs[6]. In this environment, it is too difficult to imagine how the pan-European vision of a Gas Target Model would be implemented in a reasonable time frame. Some analyses show that, despite this market fragmentation, there are elements of national gas market legislation and regulation that would allow gas trading as performed in the more mature gas hubs of Europe and the US.

Map 4.4 **Ranking of EU and UK Hubs Based on Monitoring Results – 2020**



Sources: ACER[7]

This reveals that the only way forward for the appropriate development of the gas market in the region is the consistent and rapid implementation of the provisions of the Third Energy Package, at least to the extent that the countries have committed to implement it in a legally binding way, i.e. the EU Member States and the Energy Community Contracting Parties. Turkey's plans are rather ambiguous. It is making efforts to enhance competition domestically, at least at the level of wholesale supply and, to some extent, retail. However, Turkey reveals a scepticism in implementing radical legal reforms that would allow its gas market, which is by far the largest and most dynamic in the region, to genuinely open to competition from the outside, by, for example,

[6] IENE (2019), "Prospects for the Establishment of Gas Trading Hubs in SE Europe", IENE Study M49, https://www.iene.eu/articlefiles/working%20paper%20no28.pdf

[7] ACER (2021), "Market Monitoring Report 2020 – Gas Wholesale Markets Volume", https://documents.acer.europa.eu/Official_documents/Acts_of_the_Agency/Publication/ACER%20Market%20Monitoring%20Report%202020%20-%20Gas%20Wholesale%20Markets%20Volume.pdf

joining the Energy Community or, as an alternative, implementing crucial parts of the legislation for market liberalisation to which most of the countries in the region have already committed.

4.9 The Energy Security Dimension

The energy sector and pursued policies and strategies may be analysed through different angles - economic, environmental and geopolitical. The geopolitical approach to energy emphasises energy security, which in most cases appears to dominate energy policy. This stands in contrast to the economic or environmental approaches, which prioritise sustainability and competitiveness. Energy security priorities are perceived both in terms of supply routes and origin of resources. The geopolitical approach primarily considers the geographical position of a particular country or region from the perspective of the location of the energy resources and how this affects the other parameters. These normally include access, the actors that control resources, their price, existing and alternative transport routes, relations with the regional and global markets, market mechanisms and the regulatory framework that may influence suppliers and marketeers, the availability and management of these energy resources, as well as political decisions and the manner and framework within which they are made.

Although most countries aspire to the lowest possible energy dependence and the maximum use of their indigenous energy resources, whether mineral or renewables, this is not always possible, either due to lack of mineral resources (oil, gas, solid fuels) or of finances. This is often the case where a long-term import deal (e.g. for oil and gas) is preferable in economic terms to the development of local mineral resources. However, in certain cases where a country's sovereignty is at stake and the inland or seaborne transport of energy supplies is vulnerable to enemy action, then, despite the high cost, it is preferable to aim for indigenous energy source exploitation (such was the case in Nazi Germany with the local production of synthetic oil from coal using the hydrogeneration process[8]). Putting for a moment aside the energy security dimension, we observe that countries, which have managed to take advantage of their indigenous mineral energy resources, produce oil and gas, much more cheaply and have an advantage when it comes to the domestic market, where they can achieve competitive prices, or aim towards exports to secure valuable income.

Sources: Eurostat

In Europe, and this applies largely to SE Europe, because of the long peace period the region has enjoyed since WWII, many countries placed energy security as a secondary priority. Their primary concern was market development and delivering affordable energy, whether electricity or oil, to as many people as possible. It was only after the war in Yugoslavia in the 1990's and the assertiveness of energy rich Russia following the collapse of the Soviet Union that energy security started to become a major priority of strategic planning.

[8] Yergin, D. (2008), "The Prize: The Epic Quest for Oil, Money & Power", Free Press; Reissue edition

With several countries in the region until very recently relying entirely on Russian gas imports, there was a major drive soon after the turn of the century to seek alternatives. Under much pressure from the EU, the South Corridor was developed along with a number of new LNG import terminals and cross-border interconnections. However, the region still remains vulnerable due to the limited number of suppliers and to even fewer supply routes.

SE Europe and the Western Balkans

With the exception of Albania, the countries of SE Europe depend on Russia for their oil and gas supply, while Kosovo and Montenegro have no gas infrastructure at all. Particularly interesting from the geopolitical perspective, given the fixed nature of transport routes and their potential vulnerability to political conflicts or other security hazards, is gas supply. Even though the Western Balkans countries are minor consumers of gas, which accounts for only 6% of their total energy consumption, there is a number of projects and initiatives aimed at diversifying the region's energy sources and supply routes. At the moment, no country in the Western Balkans has diversified sources or supply routes when it comes to natural gas. (In the case of oil, we have a different situation since apart from a limited number of pipelines, oil is delivered freely by ship or tracks through several entry points).

In Chapter 9.2, there is a detailed analysis of existing and planned major gas pipelines (e.g. TANAP-TAP system, IGB, IGNM, IAP, Turkish Stream, BRUA, etc.) that would allow the countries of the SEE region to diversify their gas supply sources and routes, which would in turn result in lower prices and stimulate the further development of gas infrastructure in the region.

In Western Balkans, Serbia has the most developed gas infrastructure, while the gas markets in Bosnia and Herzegovina and North Macedonia are very limited. In the rest of the SEE region, Turkey is the country with the most extensive and well developed gas network, followed by Greece.

Both countries are totally dependent on Russian and Azeri gas imports via pipeline but also from substantial LNG quantities.

The Western Balkans and SE Europe in general remain a poorly connected region in terms of energy infrastructure, with almost secluded energy markets often burdened by political instability. The region will continue to face three fundamental challenges. The first concerns insufficient investment in energy infrastructure, addressed by the EU's energy and climate targets for 2030. The second is the lack of clear and enforceable measures to ensure the preparedness of energy systems and their response to potential shocks in the event of an interruption to gas or oil supplies or other types of energy shock (e.g. electricity grid problems). The third challenge is reflected in the activities of external actors, who exploit clientelism of political elites in the region in order to oppose the implementation of EU policies as exemplified by the Energy Community goals in Western Balkans countries.

This last challenge is exacerbated by divergent conceptual understandings of energy security among countries in the region, on the one hand, and the EU, on the other. Countries tend to prioritise availability of resources, investments, or loans for the energy sector without any required reforms The EU promotes energy transition, transparency and investments tied to specific reform requirements.

Geopolitical Dilemmas

In stark contrast to the furor caused by the Nord Stream 2 gas pipeline, following the imposition of sanctions - since lifted - by the US, going back to 2018, when the project was launched, TurkStream, which brings Russian gas to Turkey via the Black Sea, and from there to the rest of SEE bypassing Ukraine, has elicited no such sanctions. Hence, from January 2020, gas supplied to the region by Gazprom is now delivered exclusively via Turkey to Bulgaria, Greece, North Macedonia, Serbia, Bosnia and Herzegovina, and will soon flow to Hungary and from there to Austria.

Construction of the TurkStream pipeline started in early 2017 and was completed at the end of 2019 with first gas deliveries to Turkey taking place on January 1, 2020. Turkstream replaced SouthStream, which had been designed to land in Bulgaria. Strong EU and US pressure on the Bulgarian government led to the pipeline's cancellation in December 2014.

TurkStream runs 930 km across the Black Sea from Anapa in the Russian Caucasus to Kiyikoy, west of Istanbul. It has a total capacity of 31.5 bcm per year through its two strings, with almost half of the quantities destined for the domestic Turkish market[9]. In essence, TurkStream has replaced completely the Soviet-era Trans Balkan Pipeline in operation since 1988, which has been piping Russian gas to Turkey, Greece, Bulgaria, Romania and Moldova originating in Ukraine. Since the start of TurkStream's operation, Ukraine has lost revenue estimated at $2.5 billion annually from the loss of transit fees for some 20 bcm of Russian gas per year[10, 11].

The timely completion and operation of TurkStream contrasts starkly with delays in the construction of Nord Stream 2[12], which suffered strong reactions from Eastern European countries that are EU members. Nord Stream 2 is slated for operation before the end of 2021[13], two years later than its sister pipeline. Nonetheless, Moscow's original strategic plan to completely bypass Ukraine appears to be coming to completion. Thus, a total of 142 bcm of Russian gas could be delivered to the main European markets and SEE through a combination of the Nord Stream complex (Nord Stream 1+2) and TurkStream, roughly corresponding to 80% of annual average Russian gas deliveries to Europe. This grand Ukraine circumnavigation plan, devised by the Kremlin, owes its origin to Ukraine's defiance of Moscow's commercial commitments, in the crises of the winters of 2006 and 2009, when Kiev suspended forward shipment of Russian transiting gas quantities destined for European clients in order to serve its own needs. To that, one should also add mounting disagreement at the time over transit fees and the cost of Russian gas purchased by Ukraine to cover its own needs[14].

Although the financial damage TurkStream inflicted on Ukraine is significant, there was hardly any reaction or fierce representations to Ankara or Moscow by Kiev or Washington, at least at the scale witnessed in the case of Nord Stream 2 over the last three years. Apparently, the economic prize was not considered that important, while at the same time there were a number of other underlying economic and political interests at play[15] between Turkey and Ukraine which prevented a flare up of public protests.

In order to understand Kiev's tame reaction to the completion and operation of TurkStream, one has to look at the regional picture. A new type of gas market is shaping up in SEE where long-term oil-indexed gas contracts are gradually giving way to gas-to-gas competition through the emergence of gas trading hubs. Already a number of such hubs are in operation in an embryonic form in SEE, while two of them (Greece's HTP and Turkey's UDN) will soon become fully-fledged hubs[16]. It would be fair to say that Ukraine aspires to partake in these developing hubs, where the Trans Balkan Pipeline could still play key role as it is still the prime energy backbone connecting all regional markets and originates in Ukraine.

Although all regional gas markets, including Greece, Bulgaria, Serbia, Romania and North Macedonia, will soon be linked via cross-border interconnectors (as described in detail in Chapter 9.2), the Trans Balkan Pipeline will remain the only single gas artery capable of shipping sizeable gas quantities from north to south and vice versa. Therefore, this gas pipeline, whose ownership and management is shared by all the national gas transmission operators, far from being decommissioned, has a role to play in strengthening energy security and ensuring greater market competition. Soon it will have a role to play in sustainabililty, too, as pipelines must be able to accommodate biomethane and hydrogen in order to comply with the new "clean gas" environment pursued by the EU[17].

The East Med pipeline is yet another major gas project in the region, still in its infancy, but it is already causing some geopolitical friction between Greece and Turkey. This planned pipeline, with a total length of 1,900 km and a yearly capacity of some 10.0 bcm, aims to ship gas from the East Mediterranean's rich gas fields (offshore Israel and Cyprus) to Europe via Greece. Although the project is still on the drawing board, it has been heavily supported by the EU. It has been included as a Project of Common Interest (PCIs) since 2014, as Brussels believes that when completed this new pipeline will further help diversify EU's gas supply. East Med, whose total construction cost is estimated at nearly $7.0 billion, is politically supported by the US as it will help lessen EU's energy dependence on Russia.

However, the East Med project is not welcomed by Turkey, which sees the pipeline as a further excuse by Greece to impose its presence in the eastern Mediterranean Sea, a large part of which is claimed by Turkey. In this sense, Turkey feels that the East Med pipeline poses a challenge to its sovereign rights in the region and has stated on repeated occasions that it

Map 4.5 **The Expanded South Corridor**

NB.: The TANAP, TAP and Turk Stream have been completed, while BRUA and IGB are still under construction. The IAP, the IGI Poseidon in connection with East Med pipeline and the Vertical Corridor and the IGF are still in the study phase. Blue Stream and Trans Balkan are existing pipelines.
Source: IENE

[17] Van Nuffel, L. et al. (2020), "Impact of the use of the biomethane and hydrogen potential on trans-European infrastructure", European Commission, https://op.europa.eu/en/publication-detail/-/publication/10e93b15-8b56-11ea-812f-01aa75ed71a1/language-en?WT.mc_id=Searchresult&WT.ria_c=37085&WT.ria_f=3608&WT.ria_ev=search

will strongly object to the underwater pipeline crossing its EEZ[18]. As Turkey and Greece have not yet demarcated their sea borders as part of an overall EEZ agreement, plotting the route of the East Med poses some technical challenges and an alternative route may have to be agreed.

Seen in a broader perspective the construction and operation of huge gas infrastructure projects, such as Nord Stream, TurkStream and East Med, inevitably carries a heavy political concomitant burden as the rearrangement and reshuffling of gas flows causes ripple effects at various levels. They alter the energy security architecture and redistribute income from gas sales and transit fees. Judging from experience so far in the European scene, we see that in most cases energy security, at both the demand and supply end, prevails over all other considerations. In the case of SEE, the energy security dimension in major gas infrastructure works is even more apparent.

Conflicts and Cooperation in the East Mediterranean

The recently discovered oil and gas fields in the Eastern Mediterranean have inspired a powerful energy alliance between Greece, Cyprus, Israel and lately Egypt, which challenges Turkey's role as the primary energy hub of the region. Tensions between Greece and Turkey over Eastern Mediterranean oil and gas fields, intertwined with maritime claims, rapidly escalated in the summer of 2020. On August 10, 2020, Turkey sent the Oruc Reis research ship, accompanied by warships to explore for hydrocarbon resources in the waters between Crete and Cyprus, which Greece claims as its own. Since then Greece has responded by sending warships in the area, and on one occasion both countries' vessels collided. The escalation of Greek-Turkish relations has compromised the energy ambitions of private actors and regional nation-states and has exacerbated an already challenging regional security environment. (10)

Regional tensions and skirmishes between Greece and Turkey are nothing new. Greece and Turkey have historically disagreed on the status of Cyprus, following Turkey's 1974 invasion on the island and its continuing occupation. This resulted in the establishment of the Turkish Republic of Northern Cyprus, solely recognized by Turkey. The proximity of the Greek islands to the Turkish mainland has also been a source of friction and disagreements. Most notably, in 1996, the two countries almost went to war due to a series of disputes over the demarcation of exclusive economic zones (EEZ), territorial waters, continental shelf, international flights rights, and demilitarisation of Greek islands in the Aegean Sea. (11)

On February 27, 2020, Turkey's announcement that it would not be able to keep migrants from entering the EU[19] renewed tensions between Ankara and the block, and the resultant migrants crossing from Greece and Turkey, among other issues, have strained relations between the two countries in 2020. Moreover, Ankara's decision to turn Hagia Sophia, a Byzantine-era cultural and historical landmark, back into a mosque, provoked public feelings in the Greek Orthodox world and received serious disapproval from Greece and several other countries, including the US.

A major paragon of the current crisis has been the result of both countries' competition over securing hydrocarbon reserves and their ongoing tensions regarding EEZ claims over large chunks of sea territory. Turkey has argued that Cyprus's resources should be shared and in defiance has carried out a number of drillings (in 2018 and 2019[20]) within Cyprus's internationally recognized EEZ, clearly trespassing the island's sovereignty. Turkey stepped back from drilling in September 2020. However, in November 2020, Ankara signed an agreement with the then UN-recognised Libyan Government of National Accord (GNA), establishing an EEZ from the southern Turkish coast to the northern Libyan coast, ignoring Crete's

[18] Daily Sabah (2020), "Ankara slams EastMed pipeline, opposes any gas project excluding Turkey", https://www.dailysabah.com/diplomacy/2020/01/03/attempts-to-exclude-turkey-in-east-med-futile-foreign-ministry-says
[19] https://blogs.lse.ac.uk/europpblog/2020/03/25/greek-turkish-border-crisis-refugees-are-paying-the-price-for-the-eus-failure-to-reform-its-asylum-system/
[20] https://www.ceps.eu/wp-content/uploads/2021/05/PI2021-09-Turkey-and-the-Eastern-Mediterranean.pdf

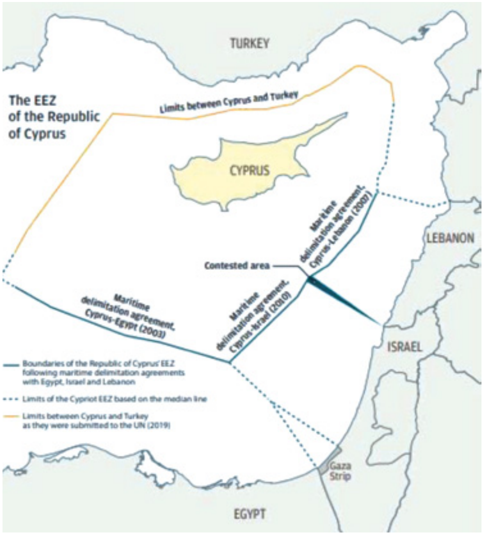
territorial waters, Greece's EEZ and continental shelf (12). In early August 2020, Greece and Egypt reached a deal, creating a partial EEZ between the two counties' coasts, which contradicted the Turkish-Libyan agreement. This resulted in Turkey's decision to send the Oruc Reis research ship near the small Greek island of Kastellorizo. Since the incident in the summer of 2020, tensions have been high with Turkey threatening Greece with war if it does not withdraw its naval vessels from the area. In a show of support, the US and France have sent their warships to the region and conducted numerous military exercises with Greece.

Background to the Overlapping Claims between Greece and Turkey in the Aegean and the East Mediterranean

There is no area more suitable than the Eastern Mediterranean where energy related geopolitical conflicts can best be illustrated. Here we have two neighboring countries which have progressively grown more hostile to each other as certain key events have occurred since the early part of the 1970's. A strong antagonism took hold as oil and gas resources were discovered by Greece in the northern Aegean and then in the summer of 1974 Turkey invaded the northern part of Cyprus. Hence, Greece and Turkey have been at loggerheads over a number of issues mainly related to the delimitation of sea boundaries and the definition of EEZ.

One would need hundreds of pages to review the entire Greek-Turkish conflict on the maritime border demarcation issue and in addition cover Turkey's strong objections of Cyprus's right to an EEZ, even though this has been declared following lengthy negotiations with neighboring countries, i.e. Egypt, Israel and Lebanon (see Map 4.6). Given Turkey's strong presence in the East Mediterranean on account of its extensive coastline and cultural ties with most countries in the region and the Greece-Cyprus axis which is exerting an equally strong influence in SE Europe, and given the history of recent incursions by Turkey in the vicinity (Invasion of northern Cyprus in 1974 and more recently in northern Syria) in the case of EEZ disputes between all above three countries, we have in this situation the seeds of a potentially huge conflict which could easily spill out politically and militarily and destabilize the entire Mediterranean.

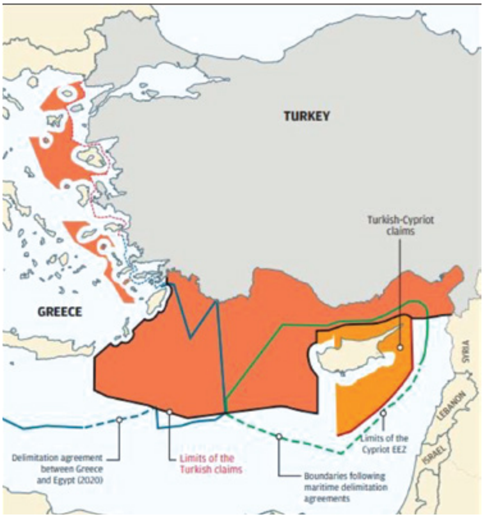
Map 4.6 **The EEZ of the Republic of Cyprus**



Source: Syrigos, A. and Dokos, T. (2020), "Atlas of Greek Turkish Relations"

In order to appreciate the enormity of the issue, we have selected a number of maps taken from the Atlas of Greek-Turkish Relations (13), which show the relative positions of Cyprus, Greece and Turkey. We start with Cyprus where Turkey on account of its unwavering position that it does not recognize the right of the island to have an EEZ, other than a very narrow strip, has on several occasions proclaimed its rights through the publication of maps (see Map 4.7) but also more actively by carrying out hydrocarbon exploratory drilling operations within Cyprus's EEZ much to the consternation of the oil companies which are already operating within Cyprus's EEZ (being the legitimate holders of exploration licenses awarded to them by the Republic of Cyprus) and to the dismay of the Cyprus's government itself.

Map 4.7 **Maritime Claims of Turkey and of Turkish-Cypriots in the Aegean and the Eastern Mediterranean**



Source: Syrigos, A. and Dokos, T. (2020), "Atlas of Greek Turkish Relations"

In the case of the Aegean and Greek seas in general, Turkey's claims on the country's continental shelf go back even further in time, in the early 1970's when Greece first discovered oil and gas in the northern Aegean, off the island of Thasos in 1970/1971. It was in 1973 when the government in Ankara first published a series of maps laying claim to large chunks of sea in the northern and eastern part of the Aegean Sea which is surrounded by islands belonging to Greece. Since then, Turkey has laid claim to a number of sea areas which Greece considers home ground in an effort to expand its own sea territory, especially following the birth of the "Blue Homeland" concept which has been systematically cultivated by Turkey over the past few years (see Map 4.8).

Legal uncertainties further complicate a possible solution of the EEZ dispute and a de-escalation of tensions in the region. Greece's maritime claims are based on the UN

Map 4.8 **Comparison between the "Blue Homeland" [Mavi Vatan] Doctrine and the Map Submitted to the UN in March 2020 Showing the Areas of the Eastern Mediterranean Claimed by Turkey**

Source: Syrigos, A. and Dokos, T. (2020), "Atlas of Greek Turkish Relations"

Convention on the Law of the Sea (UNCLOS), which provides every Greek island with maximum territorial waters (up to 12 nautical miles) and EEZ (up to 200 nautical miles) (see Map 4.9). A map, which depicts the above, known as the Seville map, and authorized by the European Commission in the early 2000s, has been dismissed by Turkey as "unjust and unfair". Although Ankara's territorial waters and continental shelf are curtailed by the full application of UNCLOS provisions and with Turkey not being a signatory to the Convention, solution of this conflict as proposed by subsequent Greek governments and several experts, can only be reached by a mutually agreed appeal to an International court, i.e. the International Tribunal for the Law of the Sea in Hamburg or the International Court of Justice in the Hague. The situation is further complicated by Ankara's maritime agreement with the GNA, which actively dismisses the territorial waters and EEZ of Greece off Crete. This is in violation of UNCLOS to which Greece is a signatory.

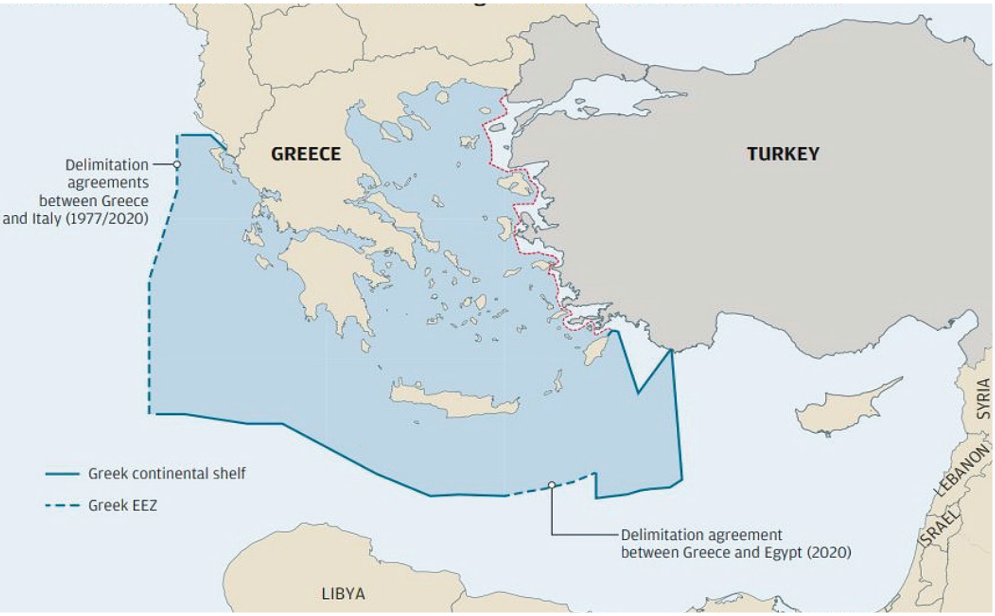
Map 4.9.1 **Greek Continental Shelf and EEZ in the Aegean and Eastern Mediterranean**

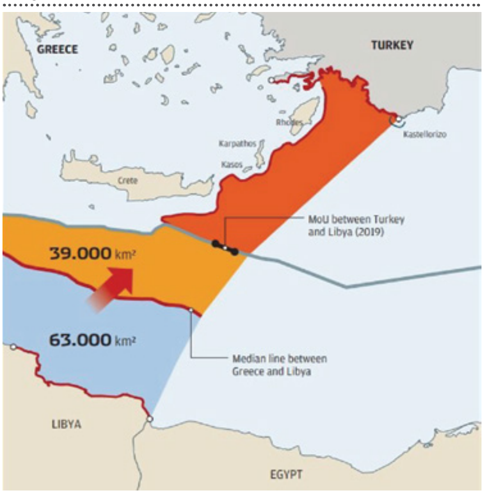


Source: Syrigos, A. and Dokos, T. (2020), "Atlas of Greek Turkish Relations"

Turkey's canning moves to secure ample maritime zones in the East Mediterranean culminated in November 2020 when a "Memorandum of Understanding" was signed between the Turkish President Reception Tayyip Erdogan and the head of the Libyan "Government of National Accord", Fayez al Sarajevo, which concerned the delimitation of maritime areas (see Map 4.10). Although the MoU has no binding authority under international law, it does constitute a precedent because of its content. And its content clearly violated the International Law of the Sea (UNCLOS) as Turkey and Libya delimited the sea region south of Crete, an area which does not neighbor with Turkey. But it should be noted that Turkey does not recognize UNCLOS which it has not signed.

However and regardless of Turkey's abstention, the International Law of the Sea has international validity as it has been ratified by more than 160 countries. Greece ratified the Convention in 1995 and is bound by it. Turkey, in contrast, voted against it. And in this move by Turkey lies the crux of the matter since by feeling not bound by UNCLOS it has a freedom of movement to declare sea areas which present a potential economic interest (see Map 4.10).

Map 4.10 **Turkey's Proposed Delimitation with Libya**



Source: Syrigos, A. and Dokos, T. (2020), "Atlas of Greek Turkish Relations"

The governments of Greece and Turkey, having long recognized the importance of finding a lasting solution concerning the demarcation of the sea areas of interest to both countries since 2002, have instituted a round of exploratory talks between high-ranking officials and so far they have held 63 such meetings with the aim of reaching an agreement on the commencement of proper negotiations over the demarcation of maritime zones. The "exploratory talks" followed the Greek-Turkish rapprochement which began in the summer of 1999 after major earthquakes in Istanbul in August that year and Greece's solidarity and help to Turkey. The agreement aimed through the above "exploratory talks" would provide for any matters not resolvable through negotiations to be referred to international talks. Following the revival of the talks in October 2020, there is speculation that an agreement may soon be feasible.

However, and in spite of the ongoing efforts to find a peaceful solution to EEZ claims and given the two countries' volatile history as on a number of occasions in the past, they were brought at the brink of war (1974, 1987, 1996, 2020), the very real prospect of an armed conflict between the two countries is still there. In this sense, exploring hydrocarbons and offshore wind potential in the Eastern Mediterranean is not only fraught with geopolitical difficulties but the area is very prone to destabilisation. This is important to bear in mind as the energy potential of the broader region in the south east flank of Europe is huge and could, if developed fully, provide an alternative energy supply to the rest of Europe. Whereas Norway has emerged as a reliable energy supplier for the EU in the north, Israel-Cyprus-Greece could develop an equal capability in the south.

The Broader Picture

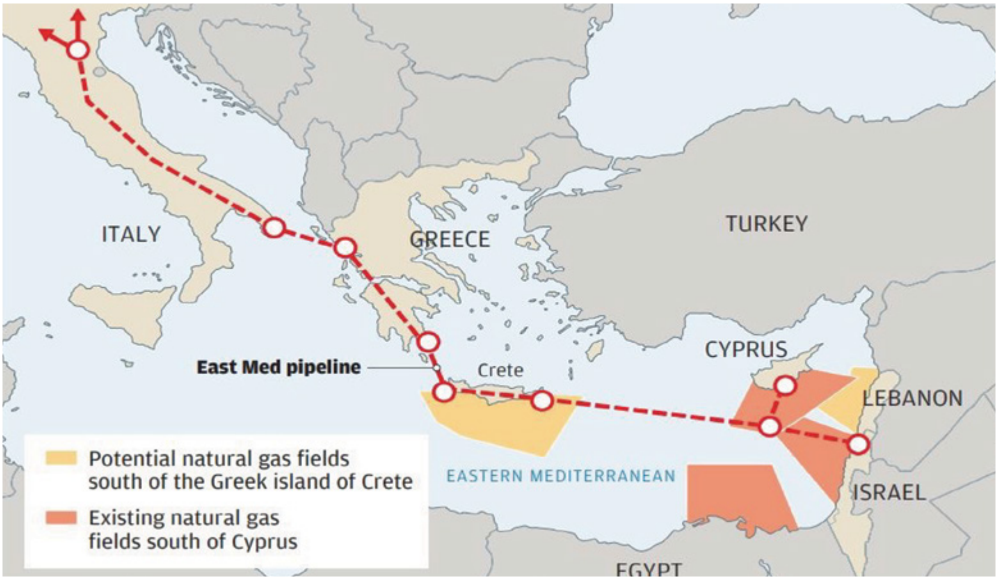
Seen in a broader context, the current maritime escalation between Greece and Turkey exceeds usual neighborly quarrels, as it adds tension to an ongoing struggle for resources in the Eastern Mediterranean. Since Israel's discovery of the Leviathan gas deposit in December 2010 and Egypt's discovery of the Zohr gas deposit in 2015, the previously deemed oil-and-gas-free region has attracted the attention of international investors and European and Middle-Eastern states. The discoveries of Leviathan and Zohr and Cyprus's Aphrodite gas field in 2011 and subsequent discoveries offshore Cyprus since then (see Chapter 8) have encouraged the strategic co-operation between Israel, Greece, Cyprus, and Egypt, which formed the East Med Gas Forum (14). This powerful geopolitical alliance apparently challenges Turkey's ambitions of becoming a major maritime energy player in the region.

Furthermore, on January 2, 2020, Greece, Cyprus, and Israel signed an intergovernmental agreement to build a 1,900-km pipeline, known as the East Med, transmitting natural gas to Europe and bypassing Turkey. As discussed in Chapter 9.2, progress on this project has been slow with the detailed engineering study, backed by EU funds, slated for completion by the end of 2021. If this project is implemented, the East Med pipeline could cover almost 4% of EU's gas supplies from Israeli and Cypriot fields (see Map 4.11). Meanwhile, drillings off Cyprus's waters were temporarily put on hold due to Covid-19 complications, while the American ExxonMobil, Qatar Petroleum, and Italian Eni, among other key players, have stated (summer 2021) that they intend to resume their exploration efforts from early 2022 onwards.

In addition, with its continuing claims in the East Med, off Cyprus and Greece, Turkey is now focusing on the development of its substantial gas resources it discovered in 2020 in the Black Sea. In June 2021, Turkey announced a major discovery of new gas deposits in the Black Sea, where the country plans to start production in 2023. State energy company TPAO found 135 bcm of gas at the Amasra-1 offshore well, bringing the total amount of deposits discovered over the past year to 540 bcm; thus, confirming Turkey's vital role as a potentially major energy supplier. (15)

Even so, local resources are unlikely to satisfy Turkey's gas consumption, estimated at 50 bcm in 2020. Although we cannot at this stage accurately estimate the amount of gas that will be produced, it is understood that it will be no less than 10 bcma. Regarding Israel, the United Arab Emirates' Mubadala Petroleum, which belongs to Mubadala Investment Co, a sovereign wealth fund with $232 billion in assets,

Map 4.11 **The East Med Pipeline**



Source: Syrigos, A. and Dokos, T. (2020), "Atlas of Greek Turkish Relations" signed a memorandum of understanding in April 2021, to buy a 22% stake in Israel's Tamar offshore field. Once completed, this will be the biggest business deal between the two Middle Eastern nations since they normalised their ties in August 2020[21].

While the recent escalation in the Occupied Palestinian Territories and Israel's intermittent bombing of the Gaza Strip are expected to significantly increase the political risks associated with investing in Israel's oil and gas sector, they are unlikely to deter Mubadala from completing this landmark deal. The UAE has a lot to gain from the purchase, believed to be worth as much as $1.1 billion, both economically and politically. Moreover, Israel is determined to complete the Mubadala deal at any cost, as it will stimulate more foreign investor interests in its oil and gas sector. To fully understand the significance of this deal, and why it is likely to go forward regardless of the latest round of conflict in the region, we need to look at the dynamics that led to its creation.

Israel is planning to launch a new bidding round for exploration and development licences in the marine territories surrounding its main gas fields – Tamar, Leviathan, Tanin and Karish – in the near future. It hopes that by issuing such licences it can significantly increase the volume of natural gas reserves that will be available to the country in the long run. To achieve this goal, however, it needs to attract interest from major international oil companies (IOCs) – something it struggled to do in its previous bidding rounds. Indeed, Israel's gas fields drew little interest from the main Western IOCs in the past, with the exception of Houston-based Noble Energy and, more recently, Chevron. The majority of industry giants, including ExxonMobil and Total, abstained from participating in Israel's previous bidding rounds, justifying their decision by pointing to the "complex" geopolitical situation around the country's energy resources.

Israel's gas fields may not be large enough to secure unconditional interest from the leading IOCs, but they are too large for the gas extracted from them to be consumed exclusively within Israel. As a result, to attract IOC interest and make use of these resources, Israel needs to demonstrate that the gas it will extract can be exported. But this is by no means an easy task and Israel will have to invest a little more on its external relations.

To enter the Asian markets, Israel will need to develop LNG liquefaction production capabilities – something it currently does not have. Moreover, these markets are highly competitive, so the Israelis may not be able to break into them even if they develop the necessary production capabilities. Hence, the only practical route at present is through Egypt's LNG export terminals and later through the planned East Med gas pipeline, which is to export gas exclusively to European markets. On top of the political and operational obstacles preventing Israel from securing major export deals, the significant security risks facing its fields are also posing a problem for its energy ambitions. In recent years, the Israeli authorities have been forced to admit that the country's oil and gas infrastructure is vulnerable to attacks from Gaza.

Despite tensions over exploration and production rights in the Mediterranean Sea bed, there is a huge economic and commercial potential to be exploited for the benefit of all, should the various warring parties decide to reach an agreement. As exploration continues, once the Covid-19 obstacles are overcome and more gas finds are confirmed, the region could well become a net gas exporter once local demand is satisfied. An excellent analysis by Marika Karagianni on "Energy: Factor of Stability or Conflict in the Eastern Mediterranean?" discusses in detail the viable export options and the opportunities. So the region, given some diplomacy and commercial cooperation, could well be transformed into an energy community. (16)

Country Profiles

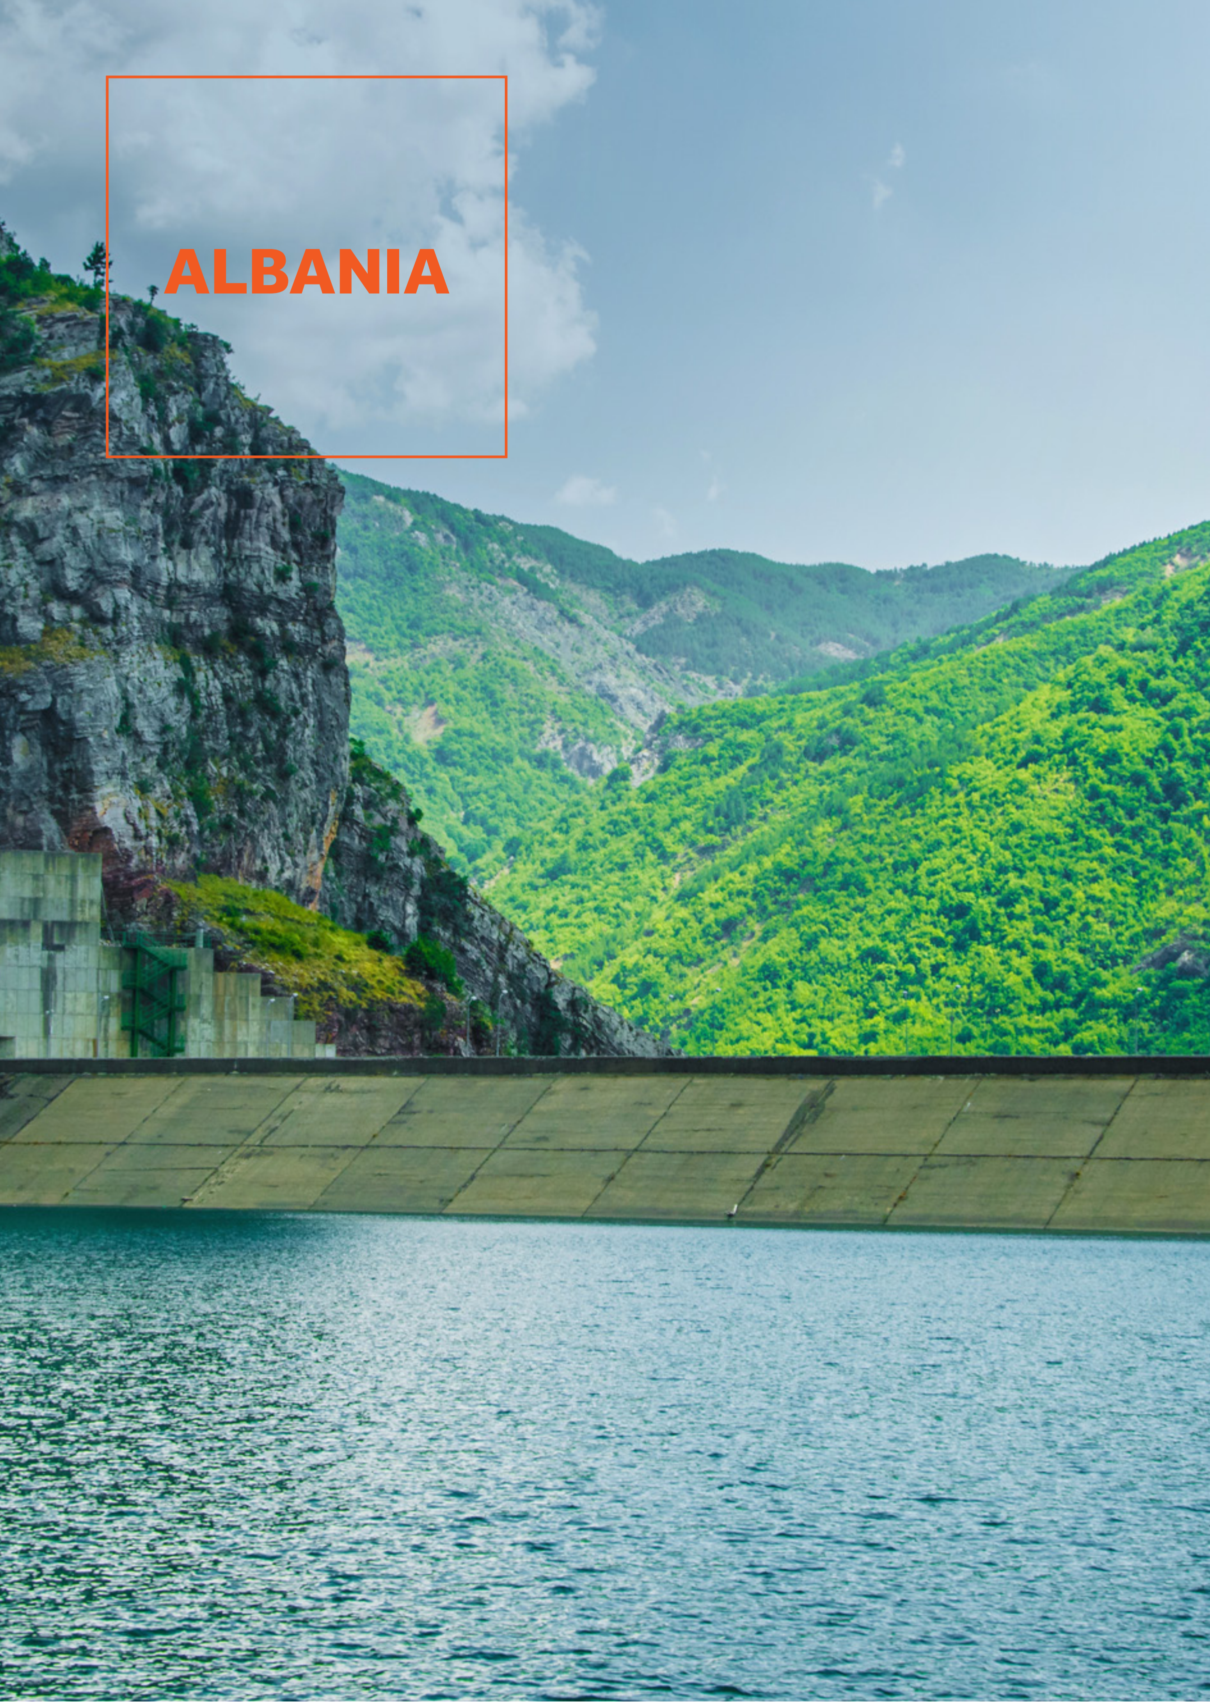
Introduction

In order to understand the energy structure of S.E. Europe it is important to have some basic knowledge on: (a) how the energy sector is organized in each one of the countries from a legal and administrative point of view, and (b) the basic energy magnitudes of each country, including energy production from indigenous sources, energy imports and exports, installed electricity capacity, refining capability, etc.

Such information is presented in a concise manner, wherever possible, for the following countries :

- **ALBANIA**
- **BOSNIA AND HERZEGOVINA**
- **BULGARIA**
- **CROATIA**
- **CYPRUS**
- **GREECE**
- **HUNGARY**
- **ISRAEL**
- **KOSOVO**
- **MONTENEGRO**
- **NORTH MACEDONIA**
- **ROMANIA**
- **SERBIA**
- **SLOVENIA**
- **TURKEY**

ALBANIA



Albania

Economic and Political Background

Albania's GDP declined by about 3.31% in 2020, based on preliminary estimates the country's statistical office released. In the fourth quarter alone, GDP grew by 2.99% year-on-year. On a quarterly comparison basis, GDP expanded by 1.15% in the three months through December.

The sectors that gave a negative contribution to GDP growth in the fourth quarter of 2020, as compared to the same period of 2019, were trade, transport, accommodation, food services, agriculture, forestry and fishing as well as net taxes on products. The main growth engines in the October-December period were construction, public administration, education and health, real estate activities and the industry, electricity and water group.

IMF projects that the Albanian economy will expand by 6.1% in 2021, significantly higher than -7.5% in 2020.

Table 5.1 **Main Economic Indicators for Albania Over 2015-2019**

Indicators	2015	2016	2017	2018	2019*
GDP ($ Billion)	13.03	13.47	13.98	14.56	15.40
GDP Growth (%)	2.2	3.3	3.8	4.1	3.5
GDP per Capita ($)	4,524	4,681	4,865	5,079	na
Industrial Output Growth (%)	2.58	1.90	1.90	9.12	na
Unemployment Rate (%)	17.08	15.12	13.75	12.40	na
Consumer rice (%)	1.9	1.3	2	2	2
Foreign Direct Investments (% of GDP)	8.7	8.8	7.7	8	na

Energy Policy

National Energy Policy

Albania's government programme[1] for 2017-2021 stipulates that the government will aim to further develop the electricity sector, transforming it into a financially, operationally and technically viable sector capable of meeting the growing domestic energy demand, prioritizing the integration of the domestic energy market into regional and European markets, and reducing import dependency. The government's policy will continue to be oriented towards increasing the security of energy supply to consumers, aiming at supporting the sustainable economic development of the country, through increasing employment and promoting renewable energy and energy efficiency, stimulating competition in the market, ensuring stability and minimizing costs for Albanian consumers, as well as ensuring environmental protection.

The Ministry of Infrastructure and Energy[2] is responsible for drafting and implementing the general state policy in the energy sector and for the utilization of energy and mining resources.

With the implementation of the National Energy Strategy , the main energy policy document adopted in mid-2018, Albania aims to achieve the following results:

- Reduced energy imports and increased domestic energy generation by meeting future energy demand in a sustainable way while enhancing social welfare;
- Improved energy efficiency in the household, services, transport, agriculture and industrial sectors;
- Increased use of RES technologies, based on least-cost planning, resource diversification, climate change and environmental protection;
- Penetration of natural gas in the Albanian energy sector through infrastructure investments;
- Development of mechanisms to encourage foreign direct investment in the Albania energy sector through increased competition in the energy market, while maintaining the interests of
- Improving the harmonization and integration of Albanian energy sector policy and regulation with energy community acquis and regional and EU markets;
- Developing a policy framework for energy (including energy efficiency for sustainable transport) in transport based on the Albanian Transport Sector Strategy, and introducing new technologies in all its sectors;
- Developing a competitive market that provides correct signals for the production and consumption of electricity and gas;
- Focused activities related to the use, rehabilitation and improvement of existing inefficient energy infrastructure that adversely affect the environment and potentially high value areas for other development sectors, such as tourism, agriculture, etc.

Some of the **concrete** objectives set by the National Energy Strategy 2018-2030 are as follows:

- Continuing to reduce losses in the electricity distribution network from 26.4% in 2017 to 10% in 2030;
- Continuing to increase electricity receipts from 90% in 2018 to 98% in 2030;
- Increase the contribution of primary energy sources to total primary energy supply at 52.5% in 2030;
- Electricity market opening rate to reach 100% in 2025;
- The Albanian economy and society reach a level of energy saving versus total consumption of 15% in 2030;
- Target of renewable energies to total consumption reaches 42% in 2030;
- GHG emissions reduction to total reach 11.5% in 2030;
- Penetration of natural gas against total supply of primary energy sources reaches 20% in 2030.

National Action Plan for Energy Efficiency (NAPEE) and National Action Plan for Renewable Energy Sources (NAPRES) (updated every 2 years) have been developed and implemented to meet the targets for renewable energy and energy efficiency.

[1] http://www.financa.gov.al/wp-content/uploads/2017/09/PROGRAMI_2017_-_2021.pdf
[2] Decision of the Council of Ministers No. 480, dated 31.7.2018 'On approval of the National Energy Strategy for the period 2018-2030'.

Governmental institutions

The **Council of Ministers** is responsible for the overall development policies of Albania's energy sector, in line with economic development policies and other sectors of the country.

The **Ministry of Infrastructure and Energy** is responsible for drafting and implementing the general state policy in the energy sector. It prepares the National Energy Strategy, mid-term programs for the development of various energy sectors, assesses the need to build new generation capacities and to strengthen energy networks, collects and processes data and information on national energy balance, develops policies and programs for the implementation of energy objectives and policies, environmental protection measures, harmonization with European Union standards and regulations in the field of energy, supervises the implementation of energy sector development policies and programs in line with the economic and social development of the country.

The **Energy Regulatory Entity** or "ERE" is the regulatory authority for the electricity and natural gas sectors in the country. ERE is an institution independent of the interests of the energy industry and state authorities, aiming at promoting and creating a competitive market and eliminating restrictions on the trading of energy products both domestically and at the level of the SEE Energy Community and beyond, as well as the sustainable development of these sectors, protecting the environment and ensuring that customers benefit from market functioning.

The **National Agency of Natural Resources** (AKBN) is an institution under the auspices of the Minister of Infrastructure and Energy. Its activity is the development, supervision of rational utilization of natural resources, based on governing policies, and monitoring of their post-exploitation in the mining, hydrocarbon and energy sectors.

The **Agency for Energy Efficiency (AEE)** is an institution under the auspices of the Minister responsible for energy. The AEE is responsible for implementing policies and promoting energy efficiency measures.

Agency responsible for renewable energy sources to be created according to Renewable Energy Law.

The **Technical and Industrial State Inspectorate (ISHTI)** conducts inspections in the field of safe processing, transportation and marketing of oil and gas and their by-products, ensuring the safety of people and material values from the risks of gas leaks and explosions caused by pressure equipment, as well as from equipment and wiring. It exercises its regulatory function in accordance with the needs of the country, national defense and public security, while respecting the principles of a market economy.

The leading public and dominant companies in the electricity sector

Albanian Electricity Corporation (KESH sh.a.), a 100% state-owned company, is the public producer and at the same time the largest producer of electricity in Albania. KESH operates the main electricity generation plants in the country. These assets consist of the Drini river cascade hydropower plants (HPP Fierza, HPP Koman and HPP Vau i Dejes) with an overall installed power of 1,350 MW, and the Vlora TPP with an installed capacity of 98 MW.

Transmission System Operator (OST sh.a) is a 100% state-owned public company that operates the electricity transmission system in Albania. OST performs the functions of Transmission Network Operator, Dispatch System Operator and Market Operator.

OST is responsible for the operation, maintenance and development of the transmission system, including interconnections with other cross-border systems, to ensure the long-term capability of the system to meet reasonable electricity transmission requirements.

Electricity Distribution Operator (OSHEE sh.a.) is a 100% state-owned public company that operates the electricity distribution network alone in Albania and performs its electricity supply function as a as Universal Service Supplier (USS) under the public service obligation. In fact, OSHEE sh.a. is in the process of dividing the company into two parts, one dealing only with the physical distribution network and its operation, and the other with the supply of electricity to customers.

In 2018 ERE has approved the separation of roles by the transfer of the license for the Electricity Distribution System Operation to the company "Distribution System Operator" sh.a. (O.S.SH sh.a.) and of the license for Electricity Supply to the company "Universal Service Supplier" sh.a. (FSHU sh.a.), that will continue to operate for a transition period under the umbrella of OSHEE SHA until the full real separation. ERE licensed also a newly established state-owned company, the "Free Market Supplier" (FTL sh.a.) in the electricity trading and supply activity. This company shall be complementary with the O.S.SH sh.a. and FSHU sh.a., but it will be completely separate from them.

Leading public companies in the hydrocarbon sector

Oil and gas exploration and production

Albpetrol sh.a. is a joint stock company established in 26.11.1998 with 100% of the shares owned by the Albanian state. Albpetrol is Albania's state-owned oil company inheriting all its oil assets and resources from the previous General Directorate of Oil and Gas. It also owns oil production fields in Fier, Ballsh, Kucova, Patos etc and is also shareholder in a few Joint Ventures it has established with international companies for the production and development of a number of existing oil fields like Patos-Marinez, Delvina, Kocove etc.

"Bankers Petroleum Albania", is a private company and operates the Patos Marinza oilfield in Albania pursuant to a licence agreement. Patos Marinza oilfield near the city of Fier is the largest sandstone onshore oil field in Europe. Bankers Petroleum has ranked the fifth largest company in Albania for years 2018 and 2019 based on its turnover. From September 2016 Bankers Petroleum Ltd. is 100% owned by the Chinese corporation "Geo-Jade Petroleum Corporation" ("Geo-Jade") [3].

Natural gas

(a) Operation and maintenance of transmision distribution systems

Albgaz Sh.a. is a joint stock company established on 07.12.2016 with 100% of the shares owned by the Albanian state. Albgaz Sh.a will operate as a combined operator performing the activity of the transmission system operator and the natural gas distribution system operator in the Republic of Albania.

Albanian Gas Service Company Sh.A was established on 17.10.2018 as a joint venture company between Albgaz (75%) and Snam (25%) as a fully operative company responsible for the maintenance and technical services for Trans Adriatic Pipeline in Albania accordance with a Joint Agreement entered between the company and TAP for such services.

TAP-AG Ltd, in accordance with the Host Government Agreement with the government of Albania has established its presence in Albania and has been licensed by ERE as a TSO and certified as an ITO.

(b) Trade of natural gas and LPG

Two LPG terminals ensuring ship unloading and LPG storage are located in Porto Romano in Durres and in the bay of Vlora in the south. Both terminals are operated by private companies respectively; "ROMANO PORT" SHA and "LA PETROLIFERA ITALO ALBANESE" SHA (PIA)
Other main companies involved in the LPG wholesale and retail markets are: IB GAS AG, INTER-GAZ SHA, A&V-GAS SHA, AV DISTRIBUTION SHA, FAM GAS L.L.C., KEVIN GAZ SHA dhe, EMANUEL GAS SH.P.K.

Trading of petrol, diesel and other by products

There are no public companies in the trade of petrol, diesel and other oil by products in Albania.**"Kastrati"** a 100% private company, for years is positioned as the main wholesale and retail trader of petrol, diesel and oil by products in Albania. Again, in year 2018 it ranked first among top 200 Albanian companies. Its turnover for year 2018 was three times higher than its closest competitor "**Genklaudis"**[4] **.**

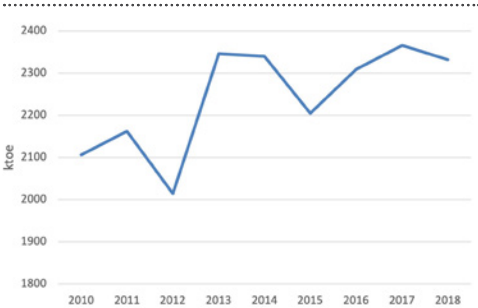
Other private companies involved in the trade of petrol, diesel and other oil by products are; **"Genklaudis", "Europetrol Durrës Albania" "Tosk Energy", "Bolv Oil", "Gega Center GKG" & "Gega Oil".**

Energy Demand and Supply

National energy demand

The gross domestic energy consumption in general has been increasing, but fluctuating throughout the period 2010-2018. In 2016 and 2017 there was an increase of consumption by 4.7% and 2.5%, respectively, compared to the previous year, while in 2018 a decrease of 1.4% compared to the previous year. Figure 5.4 shows the gross domestic energy consumption between 2010 and 2018.

Figure 5.4 **Gross domestic energy consumption 2010-2018**

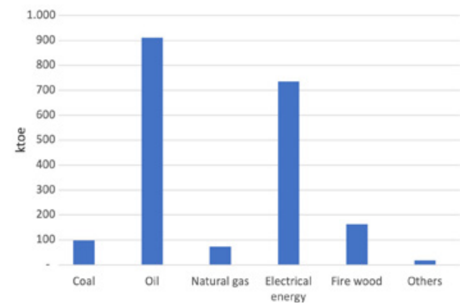


Source: INSTAT, AKBN

National energy supply

Albania produces most of the energy it consumes. Figure 5.5 shows domestic production of primary energy for 2018.

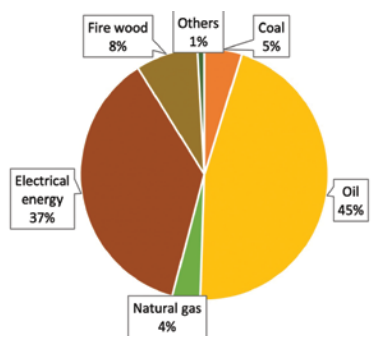
Figure 5.5 **Domestic production of primary energy products for 2018**



Source: INSTAT, AKBN

The structure of domestic production of primary energy for 2018, is shown below:

Figure 5.6 **The structure of domestic production of primary energy for 2018**



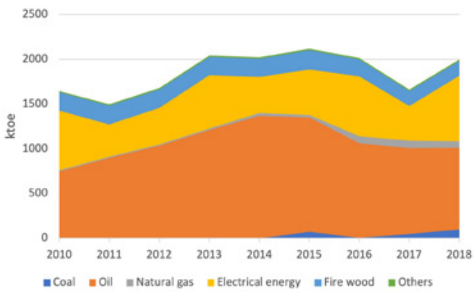
Source: INSTAT, AKBN

Domestic supply consists mainly of oil, electricity and firewood. Oil and electricity are the main indigenous primary energy sources in Albania which covered 45.6% and 36.8% respectively, of total primary energy supply contributing together 82.4% of the primary energy. The contribution of coal and natural gas is marginal, albeit with a slight increase in the last three years.

[3, 4] https://www.monitor.al/200-vip-at-e-2018-viti-i-koncesioneve-2/

Albania's total primary energy supply 2010-2018 is shown in Figure 5.7:

Figure 5.7 **Total Primary Energy Supply 2010-2018**

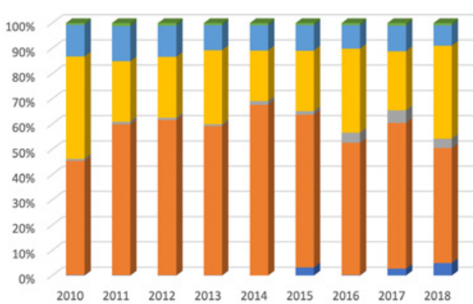


Source: INSTAT, AKBN

The supply has a slight upward trend, but often with strong fluctuations like that of 2017, mainly due to the very low production of electricity from hydro sources, which is highly dependent on weather conditions. Electricity production in 2017 was about 58% (389 ktoe) of a year earlier (669 ktoe). Oil production peaked in 2014 at 1368 ktoe, maintained stability in 2015, and has stabilized at a new equilibrium of around 1,000 ktoe during the last three years. Total domestic production of primary energy products in 2018 compared to 2010 increased by 354 ktoe or 21.5%. However, over time this performance has been fluctuating. In 2016 there is a decrease of 4.9% from the previous year, in 2017 another decline by 17.5% compared to 2016, while in 2018 an increase of 20.2% compared to 2017 and 15.9% compared to 2015.

The percentage structure of domestic supply for the years 2010-2018 is shown in Figure 5.8:

Figure 5.8 **The percentage structure of domestic energy supply for the years 2010-2018**

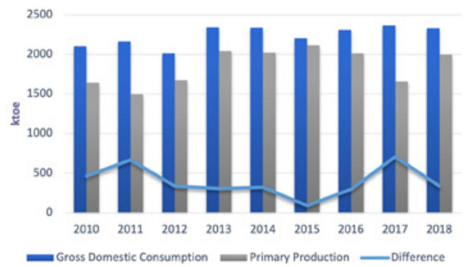


Source: INSTAT, AKBN

Energy balance

Gross National Energy Consumption, Domestic Primary Energy Production and the Difference between Consumption-Domestic Production during 2010-2018, are shown in Figure 5.9.

Figure 5.9 **Gross National Energy Consumption, Domestic Primary Energy Production and the Difference Consumption-Production during 2010-2018**



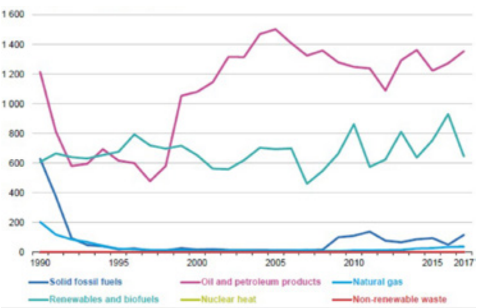
Source: INSTAT, AKBN

The difference between national gross consumption and domestic production has always been in favor of consumption. The energy deficit reached its lowest point in 2015, where consumption was slightly higher than production by only 88 ktoe. In 2016 the difference increased again to 296 ktoe. In 2017 the difference reached 705 ktoe, and in 2018 the gap narrowed again to 335 ktoe.

Energy mix

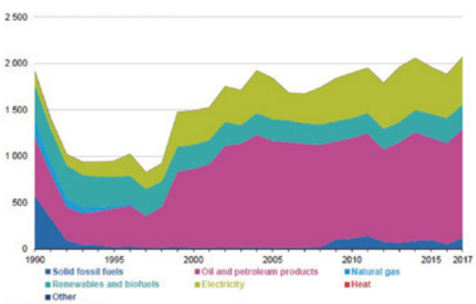
Starting from 1999 Albania's energy mix remains dominated by hydrocarbon products while electricity from renewable sources (hydro) has increased at a moderate level demonstrating at the same time high fluctuations as shown in the charts below (see Figures 5.10 and 5.11).

Figure 5.10 **Albania Gross Available Energy by Fuel (ktoe) for the period 1990-2017**



Source: Eurostat; Energy balance sheets 2017 DATA

Figure 5.11 **Albania Energy Consumption by fuel** [5]

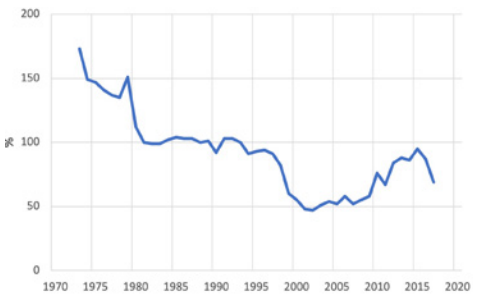


Source: Eurostat_nrg_bal_c, "Energy Balance Sheets 2017 DATA"

Energy Dependence

Until 1993 Albania covered entirely its energy demand through its own domestic resources. After 1993, mainly due to the significant drop of domestic crude oil production Albania became a net importer and its level of energy dependence went below 50% in 2002. After 2003 Albania's energy Self Sufficiency Rate (%) (Total domestic energy production/TPES) has shown a constant recovery until the year 2015 when Albania covered up to 95% of its total energy needs. In 2016 the self-sufficiency rate dropped again to 87% and further down to 69% in 2017 as shown in the chart below: As explained, one of the main goals of the current energy strategy is to attract investments in the energy sector and hence improve the degree of energy dependence.

Figure 5.12 **Self Sufficiency Rate (%) 1973-2017**



Source: IEA (2019), World energy balances 2019

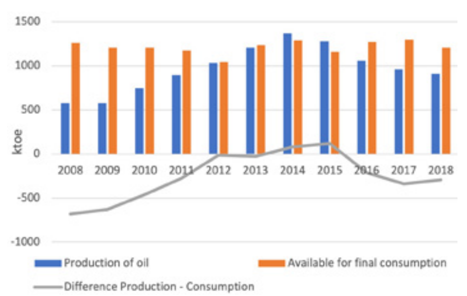
The Energy Market

Oil and Petroleum Products

(a) Oil supply and demand

During 2008-2018 Albania's domestic production of crude oil surpassed its annual consumption only in 2014 and 2015. Maximum crude oil production was reached in 2014 with 1,368 ktoe (approx. 27,360 barrels per day) surpassing the annual consumption by 81 ktoe. The annual production in 2015 was 1,279 ktoe (25,580 barrels per day) surpassing domestic consumption by 119 ktoe as shown in the graph below. The level of oil production has been highly influenced by international oil prices as well as from internal developments.

Figure 5.13 **Albania's crude oil domestic production and yearly consumption and the difference between them during the period 2008-2018**



Source: INSTAT

[5] Source: Eurostat_nrg_bal_c, "Energy Balance Sheets 2017 DATA"

Crude oil and electricity from hydro are the most important energy products of Albania. During the last decade hydrocarbons have contributed the largest share of Albania's energy balance reaching a maximum of 66.2% in year 2016.

Table 5.2 **Share of hydrocarbon products in the Albania's final energy consumption during the period 2014-2018**

Oil	2014	2015	2016	2017	2018
Available for final consumption ktoe	1,287	1,160	1,270	1,299	1,206
% to final energy consumption	62.2%	58.8%	66.2%	62.8%	58.1%

Source: INSTAT

(b) Oil imports/dependence

As explained in the previous section Albania's domestic crude oil production has been able to meet the domestic consumption of hydrocarbons only for a relatively short period of time (2012-2015). Since then Albania has become again a net importer of hydrocarbon products as domestic consumption of oil has steadily increased. The chart below provides the level of crude oil production by type of reservoir and the level of hydrocarbons imports in the country.

Figure 5.14 **Albanian domestic production (from limestone and sandstone reservoirs) and imports in ktoe**

Source: AKBN[6]

(c) Upstream sector - domestic production and exploration

After its shift to free market economy Albania adopted an ambitious strategy to attract investment in the area of oil and gas exploration and for ongoing oil and gas production. A new petroleum law was approved by the Albanian Parliament (Law No.7746, date 28.07.1993, as amended). The wholly integrated and state-owned oil and gas sector was transformed into a commercial company named Albpetrol. Albanian off shore and onshore were divided into blocks and promoted to attract foreign investments. Albpetrol was also unbundled and given the right to enter into petroleum agreements (in the form of PSA = Production Sharing Agreements) with other oil and gas companies to explore its blocks and enhance oil production from the existing oilfields. Since 2004 the government of Albania has signed 16 production sharing agreements (PSA) for the oil and gas exploration and production. Seven companies are involved in the production of crude oil in the southern part of Albania and four companies are involved in exploration activities[7]. A detailed account of exploration and production activities follows.

(i) Oil and Gas Exploration

The first area which opened for offshore exploration was in Blocks 2 and 3 (see Map 5.1). Major companies signed PSA's with the Albanian state, but so far no commercial discovery has been declared in Albanian seas.

Map 5.1 shows the current division and the status of the Albanian onshore and offshore blocks;

[6] "Bilanci Kombetar i Energjise 2017", page 8 / National Energy Balance, page 8 https://www.akbn.gov.al/wp-content/uploads/2019/02/Raporti-i-Bilancit-2017-ok3.pdf

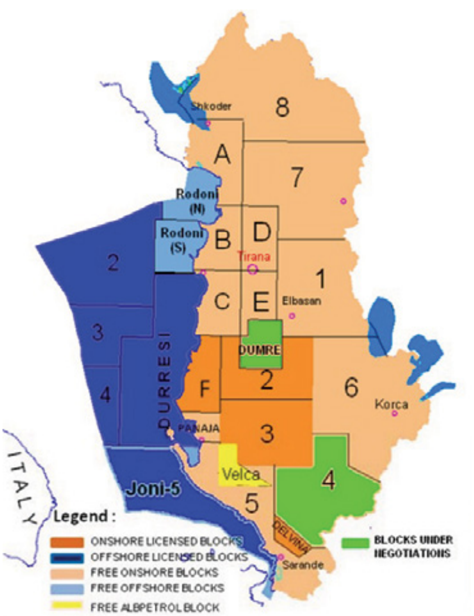
Map 5.1 **Albania Exploration Blocks**



Source: AKBN [8]

The list of Petroleum Agreements held by AKBN on 31 December 2015 as stated in the latest report of EITI are given in Table 5.3:

Table 5.3 **List of Petroleum Agreements (as of 31 December 2015)**

Operators of the PSA	Petroleum operation	Oil and gas blocks	Date of PSA
Sari Leon Energy B.V.	Exploration, development and production	Offshore exploration block Durres	August 2007
Capricorn Albania Limited	Exploration, development and production	Offshore exploration block Joni 5	September 2007
Bankers Petroleum Albania Ltd	Exploration, development and production	Onshore exploration block F	November 2010
Royal Dutch Shell plc & Petromanas Energy Inc.	Exploration, development and production	Onshore exploration blocks 2 & 3	July 2009

Source: EITI [9]

During 2016-2019 the following announcements were made by the Ministry of Infrastructure and Energy (MIE), concerning hydrocarbon exploration:

- On 15 March 2016, MIE signed a petroleum agreement with Albanides Energy Ltd, for the onshore exploration Block No 8. However, no other announcement has been made concerning progress in this block [10].
- On 20.02.2018, MIE[11] signed a petroleum agreement for oil and gas exploration for the onshore Block No 4. The contract is for 25 years with the right of renewal in case of discovery. The contract will be implemented in three phases with specific commitments for each phase.
- On 02.05.2019 MIE[12] and SHELL signed an amendment of the petroleum agreement for Blocks 2 and 3. According to MEI after several years of exploration activity SHELL confirmed the potential of an important new discovery in Blocks No 2 and No 3 in the Shpirag area in Berat district.
- On 20.12.2019 MEI[13] and Italian ENI signed a petroleum agreement for the Dumrea Block in Elbasan district. The block covers an area of 587 km^2.

In addition to petroleum agreements signed by the Ministry the following developments have taken place on Albpetrol's exploration blocks;

- On February 14, 2017 the Pennine Petroleum Corp. cosigned a production sharing agreement with Albpetrol SH.A for the exploration and development of the Velca block in Albania Source[14]. However, no further announcements have been made on the progress of its implementation.

ii) Oil and gas production

The history of Albanian crude oil production is shown in the chart in Fig.15. The whole crude oil production was under state control until year 1993. Since then several petroleum agreements (MH in the chart below,

8 http://www.akbn.gov.al/ (as of 20 April 2020)

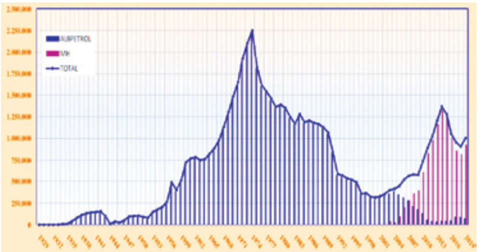
14 https://www.reuters.com/article/idUSFWN1FZ15J

Marrveshjet Hidrokarbure) have been signed for the development of the existing oil fields with Patos-Marinza being the largest existing oilfield.

Figure 5.15 **Albania's History of Crude Oil Production**



Source: AKBN

The actual figures of crude oil production for the last three years is given in Table 5.4:

Table 5.4 **Albania crude oil production during 2017-2019**

Year	2017	2018	2019
Crude oil production (tons)	955,068	910,683	1,004,998

Source: AKBN

As already mentioned, the highest level of crude production during recent years was attained in 2014 with 1,368,233 tons.

From Table5. 4 it can be easily seen that the share of production from the petroleum agreements has dramatically increased, starting from year 2004 and currently constitutes almost the total crude oil production of the country.

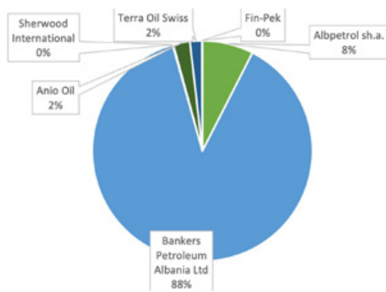
The list of the current petroleum agreements for the existing oilfields in Albania and their level of crude oil and gas production for the year 2019 is given in Table 5.5.

Table 5.5 **Crude oil and gas production for year 2019 in Albania**

no	Company	Oil Field	Oil Production (2019) tons	% to total production
1	Albpetrol sh.a.		75,415	7.52%
2	Bankers Petroleum Albania Ltd	Patos-Marinez	885,692	88.13%
3	Sherwood International	Kuçove	1,172	0.11%
4	Delvina Gas Group	Delvine	-	0%
5	Anio Oil	Ballsh-Hekal	24,439	2.43%
6	Terra Oil Swiss Transoil Group/Visokë		17,778	1.77%
7	Fin-Pek	Finiq-Krane, Pekisht-Murriz	502	0.04%
	Total		1,004,998	100%

Source: AKBN

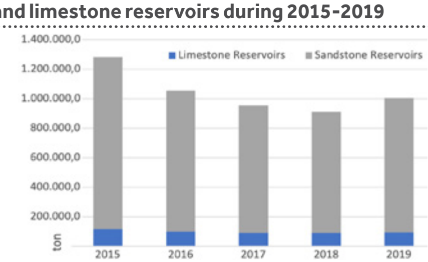
Figure 5.16 **Share of crude production from the existing oilfields for year 2019**



Source: AKBN, graph prepared by SEA Consulting

"Bankers Petroleum Albania Ltd" which is producing in the Patos-Marinza oilfield remains the dominant producer with 88% of the Albanian total production in year 2019. The oil production during the last five years (2015-2019) from limestone and sandstone reservoirs is given in Figure 5.17.

Figure 5.17 **Albania crude production by sandstone and limestone reservoirs during 2015-2019**



Source: AKBN

(d) Downstream and midstream sectors and infrastructure (Refineries, Pipelines, Storage, Terminal and Domestic Oil Market)

Albania's crude oil production is mostly exported to be refined abroad. Domestic consumption of refined oil is fulfilled through imported oil. Albpetrol pipelines are not currently operating. Two crude oil pipelines link ARMO's oil terminal in Vlora with Fieri and Ballshi refineries and the two refineries between them. Both pipelines are not operating due to obsolescence. The oil pipeline network has a total length of 188 km and a capacity of 2.5 million tons per year.

(e) Security of supply

The Ministry of Infrastructure and Energy (MEI) has initiated a public consultation for the draft law on "the establishment, storage and management of the minimal reserves of crude oil and its byproducts" which is expected to bring positive impacts on the security of supply with crude oil and its byproducts.

(f) Planned new projects

The new oil and gas projects in Albania are mainly related with to the development of the national natural gas network and its connection with the region like the IAP and ALKOGAP pipelines. Albania has prepared its gas master plan since 2016 while prefeasibility studies have been prepared for IAP and ALKOGAP. No other significant decisions have been made.

(f) Planned new projects

The new oil and gas projects in Albania are mainly related with to the development of the

Natural Gas

(a) NG Supply and Demand

An actual natural gas market does not yet exist in Albania. The current domestic production of associated gas from the existing oil fields is very modest at less than 100 MNcm/year for 2017 and is used for the technological and protection needs of the producing companies[15]. The Gas Master Plan of Albania foresees an initial gas demand at the level of 1.14 BCM/year to grow up to 2.44 BCM/year over a 20-year period.

(b) NG Imports

The only gas interconnector that makes Albania part of the Southern Gas Corridor, the Trans Adriatic Pipeline (TAP) is close to commissioning (3Q 2020) and is expected to start operations before the end of 2020. However, no local developments have taken place so far in Albania that would make possible the use of gas sources via TAP in the near future.

The TAP system will be operated by a single center outside Albania. TAP has the obligation to build two exit points in Albania with capacities to be finally agreed with the government of Albania. The locations of both exit points are already agreed at the Fier compressor station and the second one in Ura Vajgurore. In accordance with the joint decision of the energy regulators of Greece-Albania and Italy known as the Final Joint Opinion, TAP has the obligation to run market tests every two years and in case of positive results to make the justifiable exit capacities available. The government of Albania is making efforts to take advantage of the presence of transiting natural gas flows in the country.

Use of LPG (through butane and propane) started from early 2000 and has since continuously increased. The consumption data are presented in Table 5.6.

Table 5.6 **Import and consumption of LPG in Albania during 2005-2017 (ktoe)**

ALBANIA	2005	2010	2011	2012	2013	2014	2015	2016	2017
LPG (Net Imports) ktoe	64	110	114	99	159	177	208	214	285

Source: Eurostat_nrg_bal_c, "Energy Balance Sheets 2017 DATA"

There are two LPG importing terminals in the country and the number of companies involved in the LPG wholesale and retail trade is limited and has been subject of an investigation by the Competition Authority which was completed in 2017[16].

[15] AKBN "National Energy Balance" / "Bilanci Kombetar i Energjise 2017", page 9
[16] http://caa.gov.al/decisions/list/page/11

5

(c) Dependence (%)

Albanian produces only limited amounts of associated natural gas from its existing oilfields while there is an increasing amount of LPG imported to cover growing demand as shown in Table 5.7.

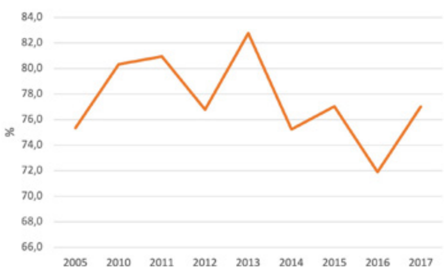
Table 5.7 **Associated gas production in Albania and LPG imports**

Natural Gas plus LPG (ktoe)	2005	2010	2011	2012	2013	2014	2015	2016	2017
Primary production (Accompanying Gas)	9	12	12	13	15	25	27	35	37
Net imports LPG (propane plus butane)	64	110	114	99	159	177	208	214	285
Gross available energy (Gas plus LPG)	73	122	126	112	174	202	235	249	322
Primary production Net imports	-55	-98	-102	-86	-144	-152	-181	-179	-248
Depen -dency (%)	75.3	80.3	81	76.8	82.8	75.2	77	71.9	77

Source: EUROSTAT, 2019

As data and the chart in Fig. 5.18 show gas consumption in Albania is highly dependent on LPG imports which was 71.9% for 2016 and 82.8% in 2013.

Figure 5.18 **Dependency from LPG imports**

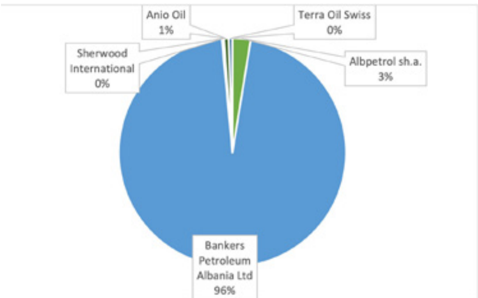


Source: INSTAT

(d) Domestic Production and Exploration

The amount of associated gas produced in Albania in 2019 was only 80 million NCM mostly produced by the Patos Marinza oilfield as shown in Fig. 5.19.

Figure 5.19 **Production of associated gas**



Source: AKBN

In May 2019 Shell Upstream Albania announced the discovery of a new oilfield in the Shpiragu region in Albania[17]. The company has started the evaluation phase of the project and initial tests have shown signs of a gas condensate discovery with high percentage of natural gas content.

(e) Infrastructure (Pipelines, Storage)

The Trans Adriatic pipeline is the main achievement so far in Albania in the natural gas sector. TAP[18] is part of the Southern Gas Corridor bringing the Caspian gas into Europe. Its initial capacity is 10 BCM capable of expanding to 20 BCM as demand increases and additional quantities of gas become available. The HGA and the energy regulators decision (Final Joint Opinion) creates all the necessary conditions for Albania to benefit from the availability of the transiting gas across the country as well as for expediting any excess gas production in the country in case of new commercial discoveries.

(f) Domestic Gas Market

Albania is a Contracting Party of the Energy Community Treaty and has continuously progressed into the adoption of the EU acqui in the energy sector. Law No. 102/2015 on the Natural Gas Sector transposes the Directive 2009/73/EC. Several other secondary legislative acts have been developed and approved and work on additional acts is progressing.

(g) National NG policy - strategic plan

The recommended scenario by the Albanian National Strategy of Energy for the period 2018-2030 is the scenario that combines energy

[17] https://ata.gov.al/2019/05/27/kerkimet-e-shell-ne-shpirag-zbulimi-i-pare-i-nje-vendburimi-te-ri-te-naftes-ne-30-vitet-e-fundit/

[18] https://www.tap-ag.al/gazsjellesi

efficiency (EE), Renewable Energy sources (RES) and promotes the use of natural gas. Being one of the three main pillars for the development of the energy sector the government has carried out the Gas Master Plan (GMP) that was approved in 2018. The GMP provides detailed analysis for the development of the gas sector following completion of TAP pipeline. However, until end of 2019 no much domestic infrastructure development has taken place in the field while TAP has announced its start of operations within 2020.

(h) Planned new projects

The main natural gas infrastructure projects articulated by the Albanian government include:

- Spur line to supply the CCGT Vlora power plant
- The Ionian Adriatic Pipeline, the interconnector that all connect Albania – Montenegro – Croatia and B&H.
- ALKOGAP, the interconnector that will connect Albania with Kosovo.

Development of underground gas storage facilities

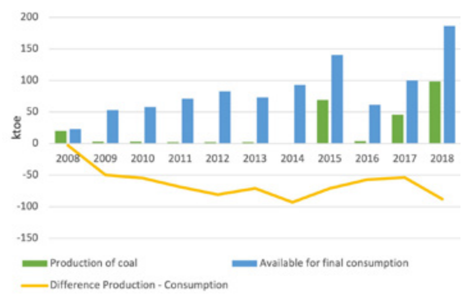
Albania has several suitable sites for gas storage, including, a salt dome in Dumrea (up to 2 bcm) and the depleted Divjaka gas field (up to 1 bcm).

Solid Fuels

(a) Supply and consumption

Domestic production of coal is at very modest levels. However, during the last 3-4 years coal consumption has increased at the level of 100 ktoe/year, out of which half is secured by domestic production.

Figure 5.20 **Domestic production of coal and the difference between consumption and production for the period 2008-2018**



Source: INSTAT

As shown in Table 5.8 the highest consumption was in 2018 constituting 9% of the total primary energy consumption.

Table 5.8 **Coal participation in final energy consumption for the period 2014-2018**

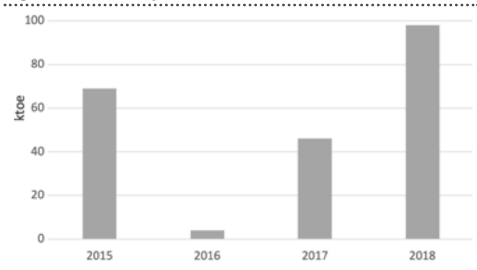
Coal	2014	2015	2016	2017	2018
Available for final consumption ktoe	93	140	61	100	186
% to Final Energy Consumption	4.5	7.1	3.2	4.8	9.0

Source: INSTAT

(b) Local production and exploration

After a long absence and following termination of coal production in 1990, Albania resumed coal production in 2015 and has since extracted coal in modest quantities (see Fig.5.21 and Table 5.9) at very modest levels.

Figure 5.21 **Coal production in Albania (2015-2018)**



Source:AKBN

Coal production in 2018 constituted 4.9% of the total of primary energy consumption in Albania. There are no developments reported in relation to any new coal extraction project.

Table 5.9 **Coal production in Albania (2015-2018)**

Coal	2015	2016	2017	2018
ktoe	69	4	46	98
% to total primary energy production	3.3	0.2	2.8	4.9

Source: AKBN

(c) Deposits

Coal

According to AKBN, Albania has considerable coal reserves. The total geological reserves discovered, so far are estimated to amount to

794 million tons. Around 85% of the reserves are located in the Tirana's coal-bearing deposit, 9,2% in Morava and Gore-Moker regions and 4.4% in Memaliaj deposits. Albanian coal reserves are of the lignite type, with a calorific value varying between 2,000 - 5,600 KCal/Kg.

Map. 5.2 **Location of lignite reserves in Albania**

Source: AKBN - www.akbn.gov.al/images/pdf/publikime/Minierat.pdf

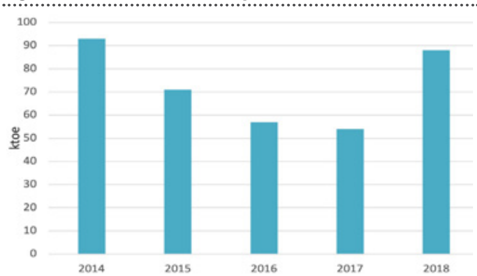
Peats (turfs)

Some peat zones are to be found along the moors of the Adriatic seaside, starting from Shkodra to Vlora and also in the Korca fields and Vurgu region. The moors where peats are found, have generally small size but should not to be underestimated. An important deposit was lately discovered in ex Maliqi moor, in Korca field. The peats discovered in this deposit are over 100 million m3, with 1,1% of sulphur content and 38,6 volatile content.

(d) Coal imports

Considering that coal consumption is modest such are also the imported amounts.

Figure 5.22 **Albania coal import**



Source: AKBN

(e) Planned new projects

No coal related projects are reported.

Electricity

Until 2018, Albania had been relying exclusively on hydropower to generate electricity. In 2019, though on a small scale, production from PV plants has begun, a trend that seems likely to continue at a higher pace. Generating electricity from natural gas is now also a distinct possibility thanks to the Trans Adriatic Pipeline, expected to start of operations by the end of 2020. The proposed 97 MW gas fired power plant at Vlora has been subject of tendering efforts by the Ministry of Energy without any concrete result so far (1Q 2020).

(a) Electricity supply and demand (in TWh)

Albania's electricity consumption reached around 7.2 TWh in 2018 and it has been growing at a moderate pace over the last ten years. The electricity demand for the year 2019 increased by 25.1% compared to 2009 with a yearly average growth of 2.26%.

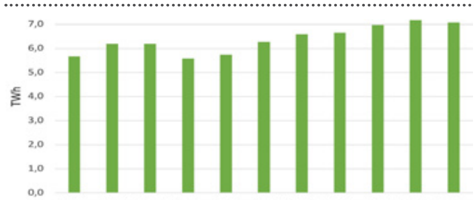
Table 5.10 **Albania's annual electricity consumption 2009-2019 (GWh)**

Years	Consumption* GWh	Annual Change %
2009	5,664	
2010	6,191	9.3%
2011	6,188	-0.1%
2012	5,578	-9.9%
2013	5,744	3.0%
2014	6,271	9.2%
2015	6,596	5.2%
2016	6,646	0.8%
2017	6,973	4.9%
2018	7,171	2.8%
2019	7,083	-1.2%

* Transmission & distribution technical losses are included. We use the term 'consumption' and not 'demand' because of the presence of non-technical losses
Source: ERE, Annual Report 2018

The dynamics of energy consumption for years 2009-2019 is also presented below:

Figure 5.23 **The dynamics of energy consumption 2009-2019**



Source: ERE, Annual Report 2018

However, electricity consumption growth rate has been irregular. In years 2011, 2012 and 2019 it has been lower than the previous year. Its complex variation is highly dependent from the level of control of non-technical losses. ERE power demand projections for for the next fifteen years period are given in Table 5.11.

Table 5.11 **Albania's annual electricity consumption 2009-2019 (GWh)**

Year	Demand (GWh)	Year (continuation)	Demand (GWh) (continuation)
2020	7,628	2028	9,079
2021	7,812	2029	9,261
2022	7,991	2030	9,446
2023	8,175	2031	9,625
2024	8,355	2032	9,808
2025	8,539	2033	9,995
2026	8,718	2034	10,184
2027	8,901	2035	10,378

Source: ERE, Annual Report 2018

The demand foreseen by ERE in the year 2035 is at around 10.4 TWh compared to 7.6 TWh in 2020. However, this forecast looks optimistic.

Table 5.12 **Albania's annual electricity production (GWh) over 2009-2019**

	Electricity Production		From which:			
Year	Total		Public Production (KESH SH.A.)		Private and Concession Production	
	GWh	Annual Change	GWh	Annual Change	GWh	Annual
2009	5,159	35.6%	4,686	37.0%	473	22.6%
2010	7,702	49.3%	7,014	49.7%	688	45.4%
2011	4,158	-46.0%	3,655	-47.9%	503	-26.8%
2012	4,722	13.6%	4,029	10.2%	693	37.8%
2013	6,957	47.3%	5,812	44.2%	1,145	65.2%
2014	4,724	-32.1%	3,409	-41.4%	1,315	14.9%
2015	5,866	24.2%	4,452	30.6%	1,414	7.5%
2016	7,136	21.7%	5,092	14.4%	2,044	44.6%
2017	4,525	-36.6%	2,917	-42.7%	1,608	-21.3%
2018	8,552	89.0%	5,851	100.6%	2,701	68.0%
2019	5,206	-39.1%	2,987	-48.9%	2,219	-17.8%

Source: ERE, OST sh.a., OSHEE sh.a.

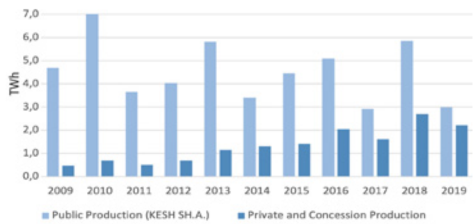
The total domestic electricity production comes from hydro generation. Despite the continuous increase of hydro generation capacity, the domestic power production remains highly dependent upon the hydrologic conditions and climate changes.

Figure 5.24 **Domestic electricity production, 2009-2019**

Source: ERE, OST sh.a., OSHEE sh.a.

Over the last years the share of power production by Small Hydro Power Producers (SHPP) largely privately owned or under concession agreements has seen a significant rise.

Figure 5.25 **The shares of public and private power generation production**



Source: ERE, OST sh.a., OSHEE sh.a.

The historical data of annual peak load in Albania over 2006-2019 is shown in Table 5.13.

Table 5.13 **Historical data of annual peak load in Albania over 2006-2019**

Years	Peak Load(MW)	Annual Changes(%)
2006	1,446	
2007	1,340	-7.3%
2008	1,397	4.3%
2009	1,306	-6.5%
2010	1,402	7.4%
2011	1,450	3.4%
2012	1,436	-1.0%
2013	1,540	7.2%
2014	1,475	-4.2%
2015	1,489	0.9%
2016	1,552	4.2%
2017	1,424	-8.2%
2018	1,480	3.9%
2019	1,498	1.2%

Source: ERE

Over the last five years a relative stabilization in peak load is observed. The electrical system is becoming more stable due also to the fact that the total installed capacity has been growing year by year.

(b) Installed Capacity (in MW)

The structure and key technical data of Albania's generating capacities according to key production technologies for 2018 is shown in Table 5.14.

Table 5.14 **The structure and key technical data of Albania's generating capacities for 2018**

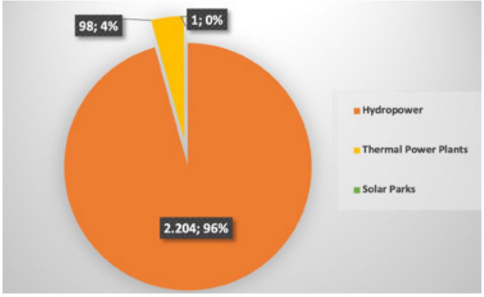
Technology	Number of units	Installed capacity		Ownership			
				Public		Concession or Private	
				Number of units	Installed capacity	No	Installed capacity
		(MW)	*%*		*(MW)*		*(MW)*
Hydro Power Plant (HPP)	165	2,204	95.70	3	1,350	162	854
Thermo Power Plant (TPP)	1	98	4.26	1	98	0	0
Solar Park (PV)	1	1	0.04	1	1	0	0
TOTAL 2018	167	2,303	100.00	5	1,449	162	854

Source: MIE, ERE, KESH sh.a.

As data shows, the capacity from hydro sources, in terms of installed capacity in MW and percentage size, remains the absolute dominant of Albania's total installed electricity capacity

.

Figure 5.26 **Total installed capacity (MW &%) per fuel type (end of 2018)**



Source: ERE, MIE, OST sh.a.

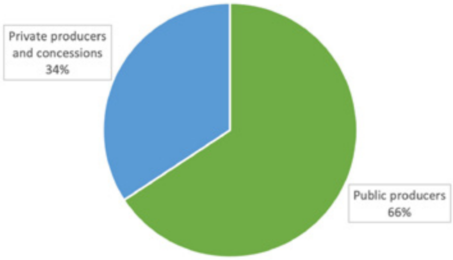
• Thermoelectric plants (coal, lignite, gas)

The only thermal power plant in Albania is the Vlora TPP with 97 MW of installed capacity which is currently not operational. This power plant can operate with two types of fuel. At the moment it can only work with diesel but it can be easily converted to natural gas. This TPP was planned to commence operation during 2011, but due to a breakdown in the cooling system, and the high cost of production with diesel the facility remains in-operational.

• Hydroelectric plants

In 2018 the total hydro installed capacity reached 2,204 MW out of which 1,448 MW or 65.7% belongs to state-controlled producers and 755.2 MW or 34.3% belongs to private producers and is run on a concession basis.

Figure 5.27 **State versus Private/Concession installed capacity in 2018**



Source: ERE, MIE, OST sh.a.

The following table provides details of hydro installed capacities according to connecting voltage level.

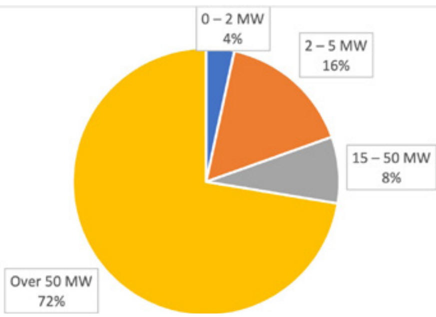
Table 5.15 **Total hydro installed capacity (end of 2018) according to connecting voltage level**

Hydropower - Grouping by Installed capacity	Connected to				TOTAL	
	Transmission Network		Distribution Network			
	No. of Units	Capacity MW	No. of Units	Capacity MW	No. of Units	Capacity MW
0 - 2 MW	7	8	81	67	88	75
2 - 5 MW	28	183	37	173	65	356
15 - 50 MW	6	177	0	-	6	177
Over 50 MW	6	1,595	0	-	6	1,595
TOTAL	**47**	**1,963**	**118**	**240**	**165**	**2,203**

Source: ERE, MIE, OST sh.a, OSHEE sh.a.

The structure of hydro installed capacity in 2018 is presented below.

Figure 5.28 **The structure of hydro installed capacity in Albania in 2018**



Source: ERE, MIE, OST sh.a, OSHEE sh.a

(c) Planned new capacity - investments

According to ERE (2018) the capacities which are in the construction process or have received preliminary approval or preliminary opinion, for their connection to the transmission network, are shown in Table 5.16.

Table 5.16 **New generation capacities under construction to be connected with the transmission network**

No.	Naming the Generation Units	Installed capacity (MW)
1	Devoll River Cascade, Moglica HPP	171.0
2	Other hydropower Plants	121.8
3	Photovoltaic Parks	7.5
Total		300.3

Source: ERE, Annual Report 2018

The biggest new power capacity expected to be commissioned in 2020 is Moglica HPP with 171 MW installed capacity.

In July, 2018, the government of Albania commenced the bidding process for the development of a photovoltaic plant project in Akerni (Vlore). The installed capacity of the plant shall be 50 MW, and it will benefit from the renewable sources support schemes. It will also have the possibility to expand with additional capacity from 20 MW up to 50 MW, but without any benefit from renewable sources support schemes. The duration of the Project Agreement is for 30 years, with the right of renewal. As part of the support measures, a Power Purchase Agreement (PPA) will be signed for a capacity of 50 MW for a period of 15 years. In November, 2018, the Ministry of Energy announced that the winner of the tender were was a consortium, following the merger of India Power Corporation ltd registered in India, Mininig Resources FZE, registered in UAE and Midami Limited, registered in Hong Kong. The award price was 59.9 Euro/MWh. Besides the announced timetable for the execution of the project, which was 18 months from the effective date, (which is the date of signing of the Project Agreement), no other progress has been reported so far. In the beginning of 2020, the Albanian Government launched another invitation to bid for projecting, financing, building, operating, maintenance and transferring of another photovoltaic power plant with 70 MWp installed capacity, in Fier area as part of renewable sources support schemes, and an additional 70 MWp installed capacity, which will not be part of the above renewable sources support schemes. The duration of the agreement between the Albanian Government-Contractor is predicted to last 30 years and the support scheme includes a 15-year Power Purchase Agreement (PPA).

(d) Electricity imports - exports

Table 5.17 **Electricity imports-exports over 2013-2019**

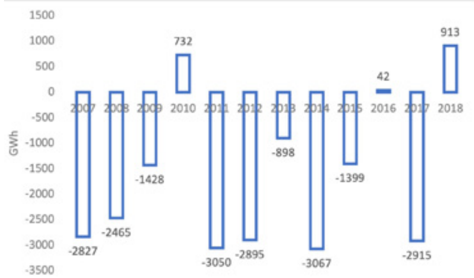
Years	Export	Import	Balance (Export - Import)
	GWh	GWh	GWh
2013	1,425	2,323	(898)
2014	288	3,356	(3,067)
2015	956	2,355	(1,399)
2016	1,869	1,827	42
2017	488	3,403	(2,915)
2018	2,685	1,772	913
2019	770	3,177	(2,406)

Note: Imports are in fact inflows and exports are outflows of electricity from the Albanian electricity system.

Source: ERE, OST sh.a.

Except for the years 2016 and 2018 Albania has been a net importer of electricity. The largest amount imported was 2,685 GWh in 2018 while it exported 3,403 GWh in the 2017. This trend is expected to continue in the near future. Table 5,17 shows selectively imports and exports for the period 2013-2019. The long-term data that is presented in Fig. 29 also shows that, with the exception of the two wet years 8the 2010 and 2018, that Albania has been a net importer of electricity.

Figure 5.29 **Electricity balance of imports - exports over 2007-2018**



Source: ERE, OST sh.a.

(e) Tariffs

Albania does not yet have a functional "day-ahead" and "intra-day" power markets and related activities, in compliance with the target model. Currently there is work in progress in order to establish a power exchange by the end of 2020 or during 2021.

In 2019 the majority of power (84.7%) has been traded in the regulated market. The remaining part (15.3%) was traded through bilateral contracts. The power consumption by the main groups is shown in Table 5.18.

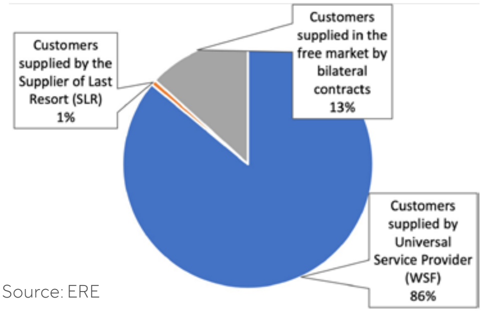
Table 5.18 **Quantity of electricity sold to each customer group**

No.	Quantity of electricity sold to each customer group	2017		2018		2019	
		TWh	%	TWh	%	TWh	%
1	At regulated prices	4.78	100	4.88	83.4	5.05	84.7
a.	Customers supplied by Universal Service Provider (WSF)	4.78	100	4.83	99.0	5.01	99.2
b.	Customers supplied by the Supplier of Last Resort (SLR)	0	0	0.06	1.2	0.04	0.8
2	At unregulated prices (Customers supplied in the free market by bilateral contracts)	0	0	0.97	16.6	0.91	15.3
	TOTAL	4.78	100%	5.85	100%	5.96	100%

Source: ERE

The share of electricity sold to each customer group in year 2019, is shown in Fig. 5.30:

Figure 5.30 **The share (%) of electricity sold to each customer group in the year 2019**



Source: ERE

ELECTRICITY/TARIFFS TRANSMISSION

There is a single transmission tariff for all users of the transmission network of OST. Sh.A. which is applied in all the transmitted power (ALL/ kWh). The transmission tariffs approved by ERE. for 2017, 2018 and 2019, are shown in the Table 5.19:

Table 5.19 **Transmission network use tariff**

No.	**Transmission network use tariff**	**Unit**	**2017**	**2018**	**2019**
1.	Transmission network use tariff	EURO/MWh	4.8	5.1	6.1

Note: The tariffs for 2017 and 2018 are equal, the changes in the above table come as a result of different ALL to EURO exchange rates in the respective years.

Source: ERE

It should be noted that the entire territory of Albania forms a single distribution zone. The distribution network operation is carried out by OSHEE sh.a, a public company (100% state owned). The distribution tariff is charged as a fee for the services offered by the use of the distribution network. The tariff is approved each year by ERE upon application by OSHEE sh.a.

The distribution tariff in Albania has remained the same for the whole period 2017, 2018 and 2019 (the changes shown in Table 5.20 below are due only to different ALL to EURO exchange rates in respective years):

Table 5.20 **Distribution network use tariffs**

No.	**Transmission network use tariff**	**Unit**	**2017**	**2018**	**2019**
11.	Distribution network use tariff				
a.	At the voltage level of 35 kV	EURO/MWh	11.2	11.8	12.2
b.	At the voltage level of 20 kV	EURO/MWh	29.1	30.6	31.7
2.	Average distribution tariff (used for all other owervoltage levels 10/6/0,4 kV)	EURO/MWh	35.7	37.5	38.9

Source: ERE

Retail prices for the tariff customer's supplied by OSHEE

The Universal Service Supplier (USS), by law, starting in 2018, should only supply electricity to the low-voltage customers (0.4 kV). Starting from 2012[19], any client that, regardless of the voltage level of the electricity network in which it is connected and has an annual energy consumption in excess of 50 million kWh, should be supplied either through the free market or by the Supplier of Last Resort (SLR).

Customers connected to the 35-kV network and above, as well as customers connected to the 20/10/6 kV network, starting January 1, 2017, are supplied either in the free market or by the Supplier of Last Resort (SLR).

But for the customers of the group 20/10/6 kV, who fail to secure suppliers in the free market due to the objective impossibility of system operators in accordance with DCM no. 449, dated 15.06.2016, the supply as a last resort of these customers is carried out on the same terms as the universal supply service at regulated prices.

[19] Law No.10485, dated 26.11.2011 "On some amendments and additions to the law no. 9072, dated 22.5.2003 'On the electricity sector", as amended, article 48, point 1.

These regulated prices for 2017, 2018 and 2019 are presented in Table 5.21.

Table 5.21 **Tariffs for medium voltage connected customers (Note 4)**

No	Medium voltage connected customers	Unit	2017		2018		2019	
			Off peak	Peak	Off peak	Peak	Off-peak	Peak
1.	Customers connected to the 20/10/6 kV network	EURO/ MWh	82.0	94.3	86.2	99.1	89.4	102.8
2.	2. Customers connected to the Medium Voltage and with metering in the Low Voltage	EURO/ MWh	92.4	106.6	97.2	112.1	100.8	116.3

Note: The exception of the group connected to the 20/10/6 kV grid are the bakehouses and the 10/6 kV flour-milling plants that are supplied at regulated prices.
Source: ERE

The electricity retail prices for end customers supplied by the Universal Service Supplier (USS), (which are the same in ALL) for the three years, 2017, 2018 and 2019 are presented in Table 5.22.

Table 5.22 **Tariffs for medium voltage connected customers (Note 4)**

No.	End customers supplied by Universal Service Supplier	Units	2017		2018		2019	
			Off peak	Peak	Off peak	Peak	Off-peak	Peak
1.	Bakehouses and flour-milling plants at 10/6 kV	EURO/ MWh	52.9	60.9	55.6	64.0	57.7	66.4
2.	Clients at 0.4 kV	EURO/ MWh	104.3	120.0	109.7	126.2	113.8	130.9
3.	Bakehouses and flour-milling plants at 0.4 kV	EURO/ MWh	56.6	65.1	59.6	68.5	61.8	71.1
4.	Households	EURO/ MWh	70.8	Not applic able	74.5	Not applic able	77.2	Not applic able
5.	Charges for electricity consumption in joint facilities (scale lightening, water pump, elevator)	EURO/ MWh	70.8	Not applic able	74.5	Not applic able	77.2	Not applic able

Source: ERE

There is also a fixed "zero" reading service fee for customers who have an active contract with OSHEE sh.a. but have no consumption during the same period. This tariff for 2017, 2018 and 2019 for this group has been around 1,5 - 1,6 EURO/contract/month.

Notes:

1. Price at peak is 15% higher than off-peak price wherever peak pricing applies.
2. The price for reactive energy is 15%of the active energy price.
3. Peak hour during which shall be applied the tariff for the consumed energy during the peak is: (a) November 1 - March 31 period from 18.00 to 22.00 (b) April 1 - October 31 from 19.00 to 23.00
4. The changes in Table 5.21 come only as a result of different ALL to EURO exchange rates in respective years
5. The changes in Table 5.22 come only as a result of different LEK exchange rates against the EURO

One should note that "Supplier of Last Resort" is a supplier (currently the state-owned OSHEE sh.a.) that provides universal service under regulated conditions, for a limited time, to the household and small non-household customers which have not managed to contract a supplier of their own or have lost their supplier.

This limited period is 2 years from the beginning of the supply contract by the SLR. The sale price of electricity supplied by the SLR is set only for customers connected to the 35-kV voltage level and is calculated by ERE on a monthly basis. ERE began to calculate this price from January 2018. For 2018 and 2019, the prices set by ERE are shown in Table 5.23.

Table 5.23 **Sales prices approved by ERE for the Supplier of Last Resort**

No. Months	Sales price approved by ERE for LRS 2018	2019
	EURO/MWh.	EURO/MWh.
11. January	90.9	152.3
2. February	74.5	113.2
3. March	74.5	108.9
4. April	74.5	111.1
5. May	74.5	110.7
6. June	77.0	106.3
7. July	100.8	103.7
8. August	100.8	103.7
9. September	100.8	104.1
10. October	125.4	113.9
11 November	125.4	119.3
12. December	119.3	134.7
Average selling price	94.8	115.2

Unregulated market information

The two big public companies, the national Transmission System Operator of electricity, OST sh.a., and the holding company OSHEE sh.a.[20], that serves as Distribution System Operator (DSO), Universal Service Supplier (USS), Free Market Supplier (FMS) as well as the Supplier of Last Resort (SLR) for electricity, have bought electricity in the free market during 2019. The quantities and respective prices are presented in Table 5.24.

Table 5.24 **Electricity purchased from state companies OST sh.a. and OSHEE sh.a. during 2019**

Months	Quantity			Price			Value (excluding VAT)		
	OSHEE sh.a.	OST sh.a.	Total	OSHEE sh.a.	OST sh.a.	Averag e	OSHEE sh.a.	OST sh.a.	Total

(f) Cross-border interconnections

Albania has six Interconnection lines with three out of four neighboring countries:

- 400 kV line Zemblak - Kardia (Greece)
- 400 kV line Tirana 2 - Podgorica (Montenegro)
- 400 kV line Tirana2 - Kosovo B (Kosovo)
- 220 kV line Koplik - Podgorica (Montenegro)
- 220 kV line Fierze - Prishtina (Kosovo)
- 150 kV Bistrica 1 - Igumenice (Greece).

The 400 kV Tirana2 (AL) - Kosovo-B (KO) is already constructed and the project is fully commissioned and ready to start operation. Besides the national Transmission System Operator, state company OST sh.a., owns and operates in total fifteen Substations (400 kV, 220 kV, and 150 kV) with a total installed capacity of 4096 MVA.

(g) Planned new projects

The TYNDP plan[21], of TSO includes the construction of the new 400 kV Interconnection Line Fier - Elbasan - Bitola (NM), as well as the extension of the 400-kV voltage level of Koman substation, to increase the transmission capacities toward Kosovo.

The interconnection line Albania - North Macedonia project includes:

- Construction of a new 400 kV transmission line Elbasan - Ohrid - Bitola, 151 km (56 km in Albania territory);
- Extension of the Elbasan2 Ss and installation of a new 120 MVAr shunt reactor.
- Construction of 68 km of new 400kV line, from Elbasan2 - Fier.
- Extension of Fier Ss, with 1 new AT-400 MVA.

Renewables

(a) Overview of sector's development

The National Energy Strategy[22] considers increasing the use of RES technologies, based on least-cost planning and environmental protection principles, resource diversification, and climate change prevention as one of the key outcomes to be achieved in the energy field. This strategy sets the target for renewable energy consumption versus total energy consumption to reach 42% in 2030. The National Action Plan for Renewable Energy Sources (NAPRES[23]) for 2018-2020 has also been approved. It sets the roadmap for achieving the national target on the percentage of energy from renewable sources consumed in the electricity (RES-E), transport (RES-T) and heating and cooling (BREH&C) sectors by 2020. The NAPRES also sets quantitative and specific benchmarks for renewable energy generation technology.

In this context, to forerun reforms in the electricity sector and achieve the 38% target of RES in the FGEC[24], the revised NAPRES for the remaining period 2018-2020, the following steps are recommended:

- Effective measures for the adoption of the secondary legation provided by law no. 7/2017 and the inclusion and diversification of renewable resources in Albania;
- Wider technical-economic analysis related to the interests of all renewables market operators in applying "support schemes" to promote RES without distinction; and

[21] Albanian TSO, Updated Ten Year Network Development Plan 2018-2028. On line: file:///C:/Users/user/Downloads/REWS_OST_112018.pdf
[22] Decision of the Council of Ministers No. 480, dated 31.7.2018 "On the approval of the National Energy Strategy for the period 2018-2030".
[23] National Action Plan for Renewable Energy Sources.
[24] Final Gross Energy Consumption.

• Strengthening the legislation on biofuels in the transport sector in terms of sustainability criteria, information / reporting, and measures to promote their marketing to the end consumer;

During 2018 renewable generation sources have been added which currently account to about 32% of our total generation resources. (ERE, AR 2018)

(b) Latest legislation, incentives and national RES policy

Law no. 7/2017 which was enacted in 2017, "On the promotion of energy use from renewable resources", partially aligned with Directive 2009/28 / EC of the European Parliament and of the Council of 23 April 2009 repealing previous Law no. 138/2013 "On Renewable Energy Sources", as amended, which was also the first integral law addressing the problems with these forms of energy.

The new 2017 law retained some mechanisms and institutions as did the old law of 2013, such as the obligation on the institutions responsible for drafting a National RES Action Plan, which is periodically reviewed, the existence of a RES responsible agency (which nonetheless had not yet been created by 2017, but its role is played by the Free Market Supplier), as well as the existence of guarantees of origin, an electronic document that has the sole function of proving to the final customer that part or all of the amount of energy used is generated by RES.

But the law changed support measures for RES electricity generation, simplified and in some cases eliminated the incentives to use solar water heating systems for the production of hot water including tax exemptions for their import and some specific provisions regarding the use of RES in transport, and introduced the concept of net energy metering.

According to this law, Albania's overall RES energy target in gross final energy consumption is 38 percent in 2020. According to the guidance of this law, the average in 2017-2018 gross final energy consumption should be 35.6%.

The legal framework offers:

(a) **The obligation to purchase electricity produced by electricity priority generators** that do not benefit from the support scheme under the contract of difference's support scheme, is considered a public service obligation and hence is charged to an ERE licensee.

(b) **Network access.** Transmission and distribution of electricity from RES is guaranteed, and producers producing electricity from RES have the advantage of access to electricity networks.

Support schemes.

Who benefits from the support schemes.

Both the 2013 and the 2017 law's provide support to all RES producers who are considered as "Priority Producers".

The 2013 law considers "Priority Producer", any producer of electricity from renewable sources, with installed capacity up to 15 MW for all power plants built by the company, which benefits from a fixed sales tariff mechanism (feed-in tariff). According to the 2017 law, the upper limit of 15 MW of installed capacity per generating unit was maintained only for a "Priority Producer" in the case of hydropower while for any other RES power producer this upper limit was removed. Also, the concept of a new group of producers called "Existing Priority Producers" was introduced, known as priority producers, from hydro resources, that regardless of the moment of signing the contract with the contracting authority, are equipped with a 'Plant Acceptance Certificate' in accordance with the relevant legislation, until the 31st of December 2020.

What are the types of support schemes?

The 2013 law theoretically provided support to all producers of electricity from renewable sources, but practically the bylaws enforced provisions only for hydropower. The support was provided in the form of Feed-in annual fixed tariffs that benefited all electricity producers from hydropower plants installed up to 15 MW each, if they did not choose to sell power in the free market. Decision of the Council of Ministers

Nr. 125, dated 11.2.2015 "On approval of the methodology for calculating the fix tariff for electricity, for the year 2015, that should be paid to electricity generators from the hydropower plants", followed by the Council of Ministers Decision No. 1033, dated 16.12.2015 which defined the "Methodology for calculating the fix tariff for electricity, that should be paid to electricity generators from the hydropower plants".

The 2017 law provides the following main supportive measures:

1. It gives the right to the Council of Ministers, upon the proposal of the Minister, **to take measures** that they deem reasonable to promote the use of electricity by RES in order to achieve the national objective of renewable energy. The law does not make it very clear what these measures are.

2. Feed-in Tariff for energy generated from small renewable sources. Electricity generated by priority generators with installed electricity capacity of up to 2 MW, and in the case of wind turbines with a capacity of up to 3 MW, is purchased by the Renewable Energy Operator at a fixed price calculated according to the approved methodologies by the Council of Ministers. This price, in the case of energy produced from hydropower, shall not be lower than the price approved by the ERE in 2016. This price shall, in the case of PV and wind technology, serve as the price level on the basis of which the beneficiaries of the contract for difference support scheme will be selected, as one of the elements of the competitive procedure.

3. Contract for Difference (CfD). The law introduced, as the main incentive mechanism for RES electricity generation, support under the "Contract for Difference". This support is based on a variable remuneration, calculated as the difference between the price at which the producer of renewable energy is declared the winner in a competitive bidding process (strike price) and the electricity market price (reference price). The CfD will have a maximum duration of 15 years. However, by January 2020, no such competitive process had yet taken place, so no one has benefited from the CfD scheme.

4. Feed-in Tariff for energy produced by "Existing Priority Producers". Electricity produced by existing priority generators is purchased by the Renewable Energy Operator at a fixed price calculated according to the methodologies approved by the Council of Ministers.

"Net energy metering scheme" is a scheme that makes the bidirectional measuring possible for small and medium enterprises or household customers, who have installed a total capacity for the production of electricity from wind or solar energy under 500 kW, which cannot be dispatched. These customers generate a part or all the energy for their own needs and can introduce the surplus energy produced into the distribution grid.

But the above bylaw only came out in June 2019 and applies only to solar (and not wind) plants. However, this legal framework has not yet become operational as 6 months have been left for OSHEE to propose to the ERE and MEI, changes to the Distribution Code and the Metering Code, which may be affected by the deployment of PV for self-consumption, and then another non-specified time which is needed by the ERE to adopt the methodology for determining the purchase price of electricity produced. Until the Methodology is adopted, the surplus energy, which exceeds the monthly consumption, will be passed on to the Universal Service Supplier without any compensation to the self-producers.

Customs duties exemptions

According to law no 8987, dated 24.12.2002 "On creation of facilities for the construction of new power capacity" and related Council of Minister's decisions, are exempt from customs duties, machineries and equipment, which are part of an electricity generation facility with an installed power of not less than 5 MW per source, using liquid or solid fuels and without limitation on other renewable sources of production.

As far as non-technical barriers are concerned prevent or delay RES development.

There are no specific issues worth mentioning other than the overall assessment of the situation for doing business in Albania. Hence, no non-technical barriers have been identified specifically for RES development.

Energy Efficiency and Cogeneration

(a) National targets

The National Energy Strategy[25] considers energy efficiency improvements on residential, services, transport, agriculture and industry sectors as one of the main results to be achieved in the energy field. This strategy sets the target for the Albanian economy and society to achieve a level of energy saving versus total consumption of 15% in 2030.

The 2015 Energy Efficiency Law[26] did not set targets, but specified[27] that they would be set by the National Action Plan for Energy Efficiency (NAPEE) 2nd and 3rd NAPEE for Albania, 2017-2020[28] analysis, concluded that "the cumulative energy savings achieved by the end of 2015 are estimated at 16.4 ktoe, which is about 0.9% of the EU Directive[29] reference consumption.

This was compared with the (extrapolated) target of 5.2% and, while the analysis could not cover all the actions implemented so far, the gap is clearly significant. Albania maintains a target of cumulative energy savings equivalent to 9% of the EU Directive[30] reference consumption (equivalent to 168 ktoe, in terms of final energy consumption, or 10 times more than cumulative savings estimated to have been achieved by the end of 2015) by the end of 2018." The targets for 2018 and 2020, based on the measures included in this NAPEE, are presented in Tables 5.26 and 5.27 below. The first table, Table 5.26 specifically stops at the final energy savings (also presented graphically in Figures 5.31 & 5.32), broken down by sectors, while the Table 5.27 shows the primary and final energy savings.

Table 5.26 **National guiding objectives in final energy savings per sector according to NAPEE 2017-2020**

Targets as per relevant sectors	Estimates of energy savings by 2018 (ktoe)	Estimates of energy savings by 2020 (ktoe)
	From measures (PL)	From measures (PL)
Houses	10.66	37.43
Services	6.27	16
Industry	3.7	6.9
Transportation	14.2	49.49
Horizontal	3.7	13.9
Total (equivalent units):	38.5	123.7
Total (GWh):	447.8	1,438.6
Percentage (%) compared to baseline scenario	2.1% (compared to baseline scenario 2018)	6.8% (compared to baseline scenario 2020)

(b) Incentive-based initiatives in the building sector (planned or already in place)

The heating of buildings in the public service and residential sectors is generally of poor performance. Albania has done little related to energy efficiency measures. Hence, there is a great potential for energy efficiency improvements.

According to Energy Community Secretariat, "despite the formal strengthening of the legal and institutional framework for energy efficiency, little was achieved by Albania to adopt the missing by-laws implementing the Energy Performance of Buildings Directive and update legislation to transpose Directive 2012/27/EU on energy efficiency. Albania thus remains non-compliant in many areas.[31]"

No incentive-based initiatives are in place yet and there are not any energy service companies (ESCOs) schemes. The government has postponed the establishing of an Energy Efficiency Fund required by the law[32] and has some dilemma about the efficiency of such mechanism.

[32] https://www.energy-community.org/implementation/Albania/EE.html
[33] Law No. 124/2015 "On energy efficiency".

But some policy measures are in place required by the laws for energy efficiency and energy building performance, which are presented below:

Table 5.28 **Energy efficiency policy measures**

Required by the law:	Policy measure	Application field / entity	Start period	Notes
On energy efficiency	Mandatory energy audit	(a) any legal person, public or private, which is categorized as a big energy consumer; (b) all natural and / or legal persons applying for a program financed by the Energy Efficiency Fund to promote and improve energy efficiency; (c) at any time before a building, industrial site and other facilities being evaluated, put into operation and / or rebuilt or subjected to substantial renovation.	End of 2015	The big energy consumers, is a final consumer, which, based on the data of an audit process, results in annual energy consumption greater than the equivalent of 3 million kWh per year.
	Mandatory measures for energy efficiency improvements	Any legal entity that is categorized as a big energy consumer and subject to mandatory auditing should, within two years of receiving the audit results, take measures and take recommended actions to improve energy efficiency.	End of 2015	
	Mandatory energy manager	Big energy consumers	End of 2015	
	Mandatory energy consumption data	Big energy consumers	End of 2015	
	Mandatory energy consumption data if required	Others energy consumers	End of 2015	
For energy building performance				
	Implementation of the requirements of the National Building Energy Performance Calculation Methodology and analysis of the possibility of using high energy performance systems	Entity that owns or will have ownership or administration responsibility for this building (When designing a new building or when a building has to undergo significant renovation);	End of 2016	
	Assessment of the possibility of using high energy efficient alternative systems should be carried out in advance	If during the phase of restructuring or renovation of buildings a replacement or renovation of the building's technical system is planned;	End of 2016	
	Mandatory certification of energy performance of buildings	a) all buildings or units of buildings which are to be sold or rented; b) all buildings to be constructed or to undergo significant renovation; c) all buildings in use by a public authority or by institutions providing a public service and frequently frequented by the public, having an area of over 500 m^2. Starting July 9, 2018, the requirement for the above limit of usable area will be reduced to 250 m^2.	End of 2016	

Source: NAPEE 2017-2020

(c) EU funded (or otherwise funded) energy efficiency programs in the building sector

According to the Agency for Energy Efficiency[34] (AEE) some projects and programs progressed in 2017-2019. These include the following:

The project "On Energy Auditing of Public Buildings" financed by the state budget aims to create the inventory of public building stock and to place data on a server of the AEE by naming and codifying them in the national electronic register, as well as to audit the entire stock of buildings for three years and to register it on the server with the data related to the costs effective analysis of their renewal.

The project financed by KfW Development Bank, "Promotion of Renewable Energies and Energy Efficiency" that aimed the rehabilitation of the dormitories of Students City No. 1 and Student City No. 2 according to the Energy Efficient principle, including interior restructuring and kitchen equipment. The target of this project was to reduce the energy performance of the dormitories to 75 kWh/m^2 per year.

The project "Development of a Financing Mechanism for Energy Efficient Public Buildings in Albania" aims to inform and facilitate decision-making for sustainable financing mechanisms for energy efficiency (EE) in the public buildings sector.

Smart Energy Municipalities is a project financed by the Swiss Embassy in Tirana and aims to support selected Albanian municipalities to manage energy in a sustainable manner and to implement the national energy policy at local level.

Study and Expert Fund measure on "Energy Management in Municipalities" by Germany/ GIZ, strengthen partner capacities in energy efficiency and to plan, prioritize and implement selective energy efficiency measures at the municipal level in 12 municipalities.

Regional Program: "ORF Energy Efficiency" by GIZ. The relevant political and civil society actors in South Eastern Europe increasingly take advantage of regional networks for the implementation of EU standards in the field of climate protection.

(d) Cogeneration: Regulatory framework, installed capacity

Albania does not yet have a co-generation regulatory framework.
UNIDO reports[35] about a project that started in 2011 in Albania aiming to increase the use of biomass in industrial energy consumption for productive use through demonstrated use of modern biomass technologies in Small and Medium-sized Enterprises (SMEs) in the olive oil industry.

The project aim is to increase the use of biomass in 15 pilot SMEs, with a capacity of about 1-1.5 MW and costing approximately € 4.5 million. No other projects of significant size are reported.

(e) Planned new major projects

Besides Vlora gas fired TPP, there are three Waste Incinerators under construction in Elbasan, Tirana and Fier, which shall be used for power generation as well. Their installed capacities are respectively 2,9 MW, and 3,85 MW each for the last two, totaling 10,6 MW.

[34] First and Second Annual Report under the Energy Efficiency Directive.

5

BOSNIA HERZEGOVINA

Bosnia Herzegovina

Economic and Political Background

There are two autonomous entities that form Bosnia and Herzegovina: the Federation and the Serb Republic. The GDP of Bosnia's Federation fell by a real 2.5% year-on-year in the fourth quarter of 2020, after contracting by 3.9% in the preceding quarter, as the entity's statistical office announced. On a quarterly comparison basis, the Federation's GDP increased by 2.8% in October-December, after rising by 5.6% in July-September.

The largest decrease of gross value added in real terms was recorded in the sectors of wholesale and retail, repair of motor vehicles and motorcycles, transportation and storage, accommodation and food service activities, arts, entertainment and recreation. In the fourth quarter of 2019, the Federation's GDP grew by 2.3% year-on-year in real terms.

The GDP of Bosnia's Serb Republic fell by a real 2.4% year-on-year in the fourth quarter of 2020, after contracting by 3.4% in the preceding quarter, as the entity's statistical office announced. In seasonally-adjusted terms, GDP increased by 2% on a quarterly comparison basis in October-December, after adding 3.5% in July-September. In the fourth quarter of 2019, the entity's GDP grew by 2.6% year-on-year in real terms.

The biggest real annual drop of gross value added in the fourth quarter of 2020 was recorded in arts, entertainment and recreation, other service activities, followed by mining and quarrying, manufacturing, electricity, gas, steam and air conditioning, water supply, sewerage, waste management and remediation activities.

IMF estimates that Bosnia's GDP will expand by 5.0% in 2021, significantly higher than -6.5% in 2020.

When it comes to political and administrative status, Bosnia and Herzegovina can be situated among world's most complex countries. The division of the country into two entities is just a tip of the political iceberg. Serb Republic's administrative division to 64 municipalities serves as a political mechanism of centralization of this entity, centered on the city of Banja Luka. The administrative solution for Federation of Bosnia and Herzegovina results in furthering the political social fragmentation.

Table 5.29 **Main Economic Indicators for Bosnia and Herzegovina Over 2015-2019e**

	2015	2016	2017	2018	2019 proj.

Energy Policy

National Energy Policy

By signing the Treaty Establishing the Energy Community, Bosnia and Herzegovina accepted a list of obligations related to the standards of the EU energy market with which it will hopefully integrate in due course. This is to be achieved by the gradual transposition of the EU acquis, which means the implementation of the relevant EU directives and regulations pertaining to electricity, gas, security of supply, environment, competition, renewable energy sources, energy efficiency, oil, statistics and infrastructure. The basic strategic goal of Bosnia and Herzegovina is to speed up the harmonization of its legislation with the acquis, and transpose and implement the obligations assumed under the Energy Community Treaty.

In the second half of 2018, "The Framework Energy Strategy of Bosnia and Herzegovina until 2035" was adopted by the Council of Ministers (the State Government). This document is based on two entities strategic documents (the Framework Energy Strategy of the Federation of Bosnia and Herzegovina and the updated Energy Strategy of Republic of Srpska) and work of the joint working group for this task. This is the first state strategic document in the field of energy. Due to the complex structure of BiH and competencies the Framework Energy Strategy is not a strategy, but a framework for a strategy. Nonetheless, this document is very important because all levels of the country (State and Entities and District) were involved in its preparation and the document was approved by the Council of Ministers (the State Government).

Priorities from the Framework Energy Strategy are as follows:

- Efficient use of resources
- Secure and affordable energy
- Energy efficiency
- Energy transition and environmental responsibility
- Development and harmonization of regulatory and institutional framework

Harmonization of Bosnia and Herzegovina's legislation with the EU acquis is a complex assignment, considering that it implies the comprehensive and essential changes to the energy sector, as well as overall sector reform. Furthermore, it is necessary to make the relevant institutions capable of establishing and implementing a new legal and regulatory framework. This segment is particularly sensitive in Bosnia and Herzegovina, considering the complexity of political, institutional and social risks[1].

As previously mentioned, transposition and implementation of acquis in Bosnia and Herzegovina has been significantly delayed. Severe deadlines have already expired and nine actions[2] have been instigated against Bosnia and Herzegovina by the Energy Community Secretariat. In the context of strategic and operational activities in the forthcoming period, a due diligence process for the harmonization of the legislation at entity and at the level of Bosnia and Herzegovina, with the EU acquis should be undertaken. These activities are necessary for the preparation of action plans and for implementing the further harmonization of legislation.

Governmental institutions

Bosnia and Herzegovina (BiH) is a state consisting of two administrative units (two

1 "Framework Energy Strategy of Bosnia and Herzegovina until 2035", 2018
2 Annual Implementation Report 2018/2019, Energy Community Secretariat, November 2019

entities), the Federation of Bosnia and Herzegovina (FBiH) and the Republic of Srpska (RS), and an internationally supervised district of Brčko (Brčko District) as a separated administrative unit. The administrative structure of Bosnia and Herzegovina is reflected in the energy sector.

According to the legal framework, the responsibility at state level is, among other things, the regulation of inter-entity transport, which includes the transport of energy. Also, foreign policy and fulfillment of assumed international obligations is the responsibility of state level institutions. The state level is responsible for the transmission network and electric power system operations and mainly for the wholesale electricity market. According to the legal framework, the entities have their own legislation for energy sub-sectors (electricity, natural gas, energy efficiency, renewable energy, oil and oil products etc.).

Bearing in mind the above, the relevant institutions in the energy sector are the following:

The Ministry of Foreign Trade and Economic Relations of Bosnia and Herzegovina (MOFTER) as a part of the Council of Ministers (the State Government) is the key institution at state level in the energy sector. MOFTER is responsible for defining policies and basic principles and for the coordinating activities and harmonization of entity level plans relevant for international relations. MOFTER has also competencies in the area of concessions of border rivers (use of water resources), as well as when the subject of concession is in the territory of both entities.

The Federal Ministry of Energy, Mining and Industry (FMERI) (entity ministry), holds authority in the fields of industry, energy, mining, geological research and entrepreneurship. FMERI is, among other responsibilities, responsible for the generation, distribution and electricity supply in the entity of the Federation of Bosnia and Herzegovina.

The Ministry of Industry, Energy and Mining of Respublika Srpska (MIER) among other responsibilities holds authority in the fields of industry, energy, mining, and geology. MIER is also responsible for the generation and distribution of electricity in the entity of Republic Srpska.

The regulatory framework of the energy sector follows the internal structure of Bosnia and Herzegovina as established by the Constitution. The State Electricity Regulatory Commission in Bosnia and Herzegovina, the Regulatory Commission for Electricity in the Federation of Bosnia and Herzegovina and the Regulatory Commission for Energy of Republic of Srpska constitute the regulatory framework which was established by the adoption of national and entity laws in the field of energy.

The State Electricity Regulatory Commission (SERC) regulates the electricity transmission system in Bosnia and Herzegovina (110 kV and above) and has jurisdiction and responsibility over the transmission of electricity, transmission system operations and international electricity trade. SERC also regulates the distribution and supply of electricity in Brčko District of Bosnia and Herzegovina.

The Regulatory Commission for Energy in the Federation Bosnia and Herzegovina (FERK), among other responsibilities has jurisdiction on the following: defining the energy prices for the supply of non-eligible customers, market monitoring, defining of tariffs for distribution systems users, licenses for generation, distribution and supply non-eligible customers, issuing the preliminary construction permits and licenses for usage of power facilities, except the facilities for power transmission. FERK also regulates oil activities.

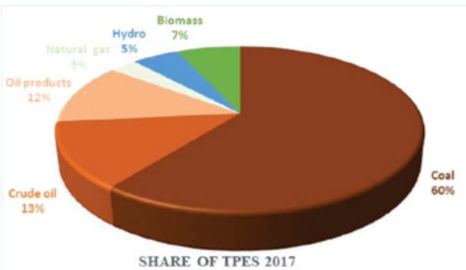
The Regulatory Commission for Energy of the Republic of Srpska (RERS) among other responsibilities has jurisdictions for: monitoring and regulation of relationships between generation, distribution and customers of electricity including traders of electricity, determination of tariff rates for distribution system users and tariff rates for non-eligible customers, licensing for generation, distribution and trade of electricity, regulates gas activities in RS, and has regulatory competences within the scope of the oil and oil derivatives sector.

Energy Demand and Supply

National Energy Demand and Supply

After reaching the post-war maximum of total primary energy supply in 2011 (7,2 Mtoe) when the pre-war supply (7,02 Mtoe) was exceeded and following 15 years of continued growth there has been a three-year supply decline that "stopped" in 2014. In 2017, the total primary energy supply of BiH was 6,8 Mtoe (Figure 5.36). This was on the level of 2016 and implies a growth of 12% compared to 2015[3].

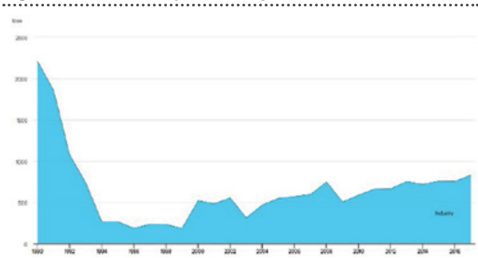
Figure 5.36 **Share of source in TPES 2017 for Bosnia and Hezegovina[8]**



Source: International Energy Agency, www.iea.org

Coal was still the main domestic energy resource as shown in Figure 5.36. The share of coal in the country's TPES was 60%.

Figure 5.37 **Industry consumption**



Source: International Energy Agency, www.iea.org

The share of transport in total energy consumption is the highest of the last 20 years. In 2017 this share was 35% of total consumption. However, if we look only at the total consumption of industry over the last 30 years (Figure 5.38), we see a different, less favorable, picture of Bosnia and Herzegovina's development. The total consumption of the industry was at 37% of pre-war consumption. In the same period consumption of transport was 70% higher compared to the 90s.

Energy mix

Generally, the energy sector of Bosnia and Herzegovina is characterized by significant domestic coal resources and the total absence of oil and natural gas production (Table 5.30). Coal production in conjunction with hydrological reserves enables Bosnia and Herzegovina to export significant quantities of electricity. But Bosnia and Herzegovina is totally dependent on imported oil and gas.

Degree of Energy Dependence

As presented in Table 5.31 and shown in Figure 5.41, the average energy dependency on imported sources in BiH was 29% of the energy consumed during 2000-2017 and was 31% of the energy consumed in the period of 2010-2017. The percentage values in last three years (2015-2017) are higher than the average energy dependency of around 29% of the energy consumed over the period 2000-2017.

Table 5.31 **Energy imports, net (% of energy use)**[5]

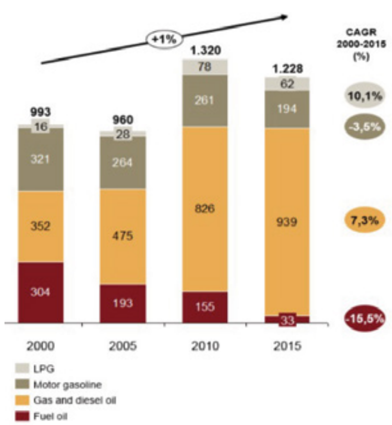
The Energy Market

Oil and Petroleum Products

(a) Oil supply and demand

Production of petroleum products in Bosnia and Herzegovina for 2018 reached 701.321 tons, while the amount of petroleum products available for supply stood at 1.639.585 tons. The final consumption in 2018 was 1.504.929 tons. The final energy consumption share in the total final consumption of petroleum products was 93% and the final non-energy consumption share was 7%. In the total final energy consumption of 1.401.257 tons of petroleum products in 2018, the largest share belonged to the transport sector (85.7%), households participated with 1.8%, industry with 6.6%, while the other, construction and agriculture sectors, participated with 5.9%. Figure 5.42 shows the annual demand for petroleum products for the period of 2000-2015, while Table 5.32 provides detailed data related to petroleum products for 2016, 2017 and 2018.

Figure 5.42 **Annual demand for petroleum products in Bosnia and Herzegovina (kt/year)**



Source:"Framework Energy Strategy of Bosnia and Herzegovina until 2035", 2018

(b) Oil imports/dependence

Bosnia and Herzegovina does not have a domestic production of crude oil and imports all necessary quantities. Generally, Bosnia and Herzegovina imports crude oil and refines a variety of petroleum products.

Yearly data (2016-2018) related to imports of crude oil is shown in Table 5.32.

Table 5.32 **Bosnia and Herzegovina, Crude Oil and Feedstock Balance** [6]

t	2016	2017	2018
Available for Supply	852.459	877.619	708.569
Production	-	-	-
Import	929.098	856.090	694.710
Export	0	0	0
Stock exchange	-76.639	21.529	13.859

Source:Energy statistics: Oil, Petroleum products, Agency for Statistics of Bosnia and Herzegovina, 2019

(c) Downstream and midstream sectors infrastructure (Refineries, Pipelines, Storage, Terminal and Domestic Oil Market)

Imported crude oil is processed in two oil refineries. The first one is the "Rafinerija nafte Brod" and is used for petroleum processing and production of petroleum products (gasoline, diesel, bitumen, LPG, fuel oil, sulphur) and the second one is the "Rafinerija ulja Modriča", which produces motor oil and various special purpose oils for the industry and other commercial purposes.

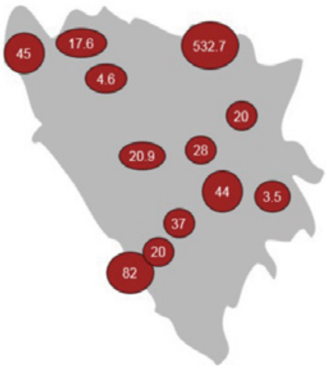
Over 90% of the processed products in the aforementioned refineries are distributed in the local market6. The petroleum products retail network is characterized by a large number of small retailers that own less than 5 petrol stations, and make up about 75% of the market. The highest consumption of petroleum products is in the transport sector, with motor gasoline and diesel used the most.

(d) Security of supply

Bosnia and Herzegovina depends entirely on imports for its oil and hence it maintains a high degree of stocks of crude oil and petroleum products. Bosnia and Herzegovina has a total of approximately 800.000 m³ of storage capacity for crude oil and derivatives, of which about 533.000 m³ are located in the "Rafinerija nafte Brod" oil refinery and 82.000 m³ in the port of Ploče operated by "Naftni terminali Federacije". The storage capacities for crude oil and derivatives in Bosnia and Herzegovina are presented in Map 5.3.

[6] Energy statistics: Oil, Petroleum products, Agency for Statistics of Bosnia and Herzegovina, 2019

Map 5.3 **Storage capacities (m^3) for crude oil and derivatives in Bosnia and Herzegovina[6]**



Source: "Framework Energy Strategy of Bosnia and Herzegovina until 2035", 2018

(e) Planned new projects

Some activity in geological exploration is in progress, but at a very low level. There are announcements that the governments (Government of Federation of Bosnia and Herzegovina[7] and Government of Republic of Srpska) are commencing with some activities related to hydrocarbon exploration. The selected hydrocarbon exploration areas are shown in Map 5.4.

Map 5.4 **Areas of hydrocarbon exploration in Bosnia and Herzegovina**

Natural Gas

(a) Natural gas Supply and Demand

Natural gas as an energy source in gross domestic consumption has a low share of total consumption for Bosnia and Herzegovina (2-3%). One of the reasons is that Bosnia and Herzegovina does not have domestic production of natural gas and does not have any installed thermal power plant gas capacities in the generation mix, which in practice represents larger consumers. The imports of natural gas to Bosnia and Herzegovina for 2018 amounted to 247.012.000 Sm^3. Natural gas consumption in the energy sector is 61.672.000 Sm^3. In a final natural gas consumption of 181.940.000 Sm3 in 2018 the industry participated with a share of 59%, households with 24% and other consumers with 17%. Historical data of natural gas consumption in Bosnia and Herzegovina by sector is presented in Figure 5.43.

[7] The end of May 2020 is the deadline for companies exploring oil and gas in the Federation of Bosnia-Herzegovina to submit official bids to the international tender of the FBiH Ministry of Energy and Mining. The tender was announced on January 7th 2020.

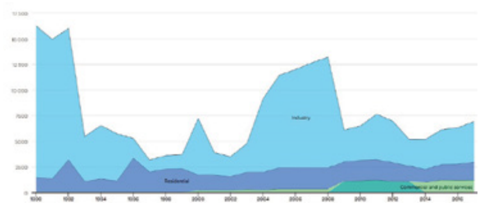
Figure 5.43 **Consumption of natural gas in Bosnia and Herzegovina by sector (TJ)**



Source:International Energy Agency, www.iea.org

(b) Natural gas Import and Dependence

The total imports of natural gas to Bosnia and Herzegovina for 2018 reached 247.012.000 Sm^3. All imported and exported quantities of natural gas are presented in Table 5.35. Practically Bosnia and Herzegovina imports the entire quantity of natural gas it uses and is 100% dependent on imports in order to meet its needs (~0,25 billion m^3/year). The country is 100% dependent on a single source and on one natural gas pipeline. Most of the gas imports for the wider region are supplied from Russian sources. Russian gas is delivered via Ukraine, and then via transit routes through Hungary and Slovakia. It is evident that the region is traditionally highly dependent on one source of gas. Having in mind that Bosnia and Herzegovina does not have its own gas resources and storage facilities, the country covers 100% of its needs through gas imports from Russia.

(c) Infrastructure (Pipelines, Storage) (current and planned)

There is only one gas interconnection between BiH with neighboring countries. This is the interconnection between BiH and Serbia. The internal existing gas transmission pipeline connects the interconnection point (BiH/ Serbia) with the cities of Sarajevo, Visoko and Zenica (Map 5.5). This single cross-border point and only one pipeline does not allow any possibility for diversified gas supplies to the country nor the provision of a minimum level of security of supply and hence is unable to attract potential new customers.

Consequently, pipeline development plans for Bosnia and Herzegovina must follow planned cross-border projects relevant to Bosnia and Herzegovina and in line with South East Europe's pipelines network. Complex political relationships within the country additionally complicate the already "difficult" situation with gas. The goal for both entities is to increase the importance of natural gas as an energy source in the economy with the aim of strengthening the integration of gas market and security of supply, but approaches are not the same.

The strategic vision of the Federation of Bosnia and Herzegovina is a systematic vertical linkage to the Croatian gas pipeline system (gas ring formation and gas supply from multiple sources: LNG, IAP or in general EU gas hubs). The goal for the Republic of Srpska is a new interconnection with Serbia in the Bijeljina area and construction of the Bijeljina - Banja Luka pipeline. Map 5.5 presents the actual situation with the pipelines (only one interconnection to Bosnia and Herzegovina-Serbia and one internal pipeline) and the plan for new pipelines.

[8] Energy statistics: Natural gas, Agency for Statistics of Bosnia and Herzegovina, 2017, 2018, 2019

Source: "Framework Energy Strategy of Bosnia and Herzegovina until 2035"

(d) Domestic Gas Market

Legislation regulating the gas sector exists only at the entities level but not at the level of Bosnia and Herzegovina. This issue for some time has been the subject of discussions between the stakeholders in Bosnia and Herzegovina. The Energy Community introduced "measures" against Bosnia and Herzegovina related to non-implementation of obligations (gas legislation on the state level) in accordance with the Third Energy Package (Energy Community Treaty). During the last year(s) the situation with further market development is unclear and unfavorable for potential investors. The actual gas market is characterized by a lack of competition and the absence of entry of new players. Furthermore, existing gas customers are not able to switch their gas supplier and gas prices are regulated.

Solid Fuels

(a)Supply and consumption

In Bosnia and Herzegovina, coal (brown coal and lignite) is the dominant energy source, accounting for 67.66% of the country's TPES in 2013 and for 58% of its electricity generation, consumed mainly by power plants near to mines. Production of brown coal and lignite in Bosnia and Herzegovina was 7,0 and 7,5 million tons respectively in 2018.

This production was 2,9% higher than previous year's production. Final consumption of brown coal and lignite was 0,42 and 0,30 million tons respectively in the same year. Consumption in energy sector of brown coal and lignite was 6,4 and 7,0 million tons respectively. Detailed data about the annual balance of coal in Bosnia and Herzegovina is shown in Table 5.36.

Table 5.36 **Annual balance of Coal and Coke-oven Coke in Bosnia and Herzegovina** [9]

(b) Local production and exploration

The coal sector is an important segment of the energy sector and an integral part of the economic structure of Bosnia and Herzegovina. Out of the total energy potential of the country, coal covers more than 90% and is rightly considered as the the dominant energy source. About 14 major mines are currently active in Bosnia and Herzegovina. The locations of key coal deposits are presented in Map 5.6. Mines, coal types and methods of extraction are given in Table 5.37.

Map 5.6 **Key coal mines in Bosnia and Herzegovina**

Table 5.37 **List of coal mines**

Mine	Coal type	Method of extraction
Rudnici Kreka d.o.o.	Lignite	Surface and underground

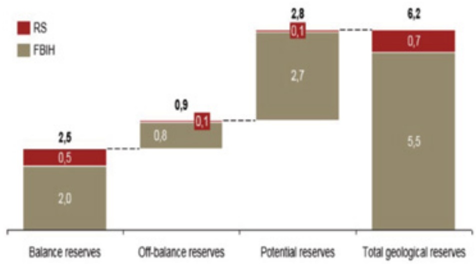
Source: Framework Energy Strategy of Bosnia and Herzegovina until 2035, 2018

(c) Deposits

According to the Framework Strategy, Bosnia and Herzegovina had (2010) 2.631 million tons of balance reserves, 604 million tons of off-balance reserves and 2.511 million tons of potential reserves. Total geological reserves amounted to 5.594 million tons of coal. The share of lignite in the balance reserve was 55% and hard coal share was 45% of the total balance reserve of coal. The structure of coal reserves is presented in Figure 5.44.

Figure 5.44 **Structure of reserves of mines in Bosnia and Herzegovina (billion t)**



Source:Framework Energy Strategy of Bosnia and Herzegovina until 2035, 2018

(d) Planned new projects

The coal industry in Bosnia and Herzegovina, as well as globally, is facing significant challenges. Historical reasons (poor geological conditions, lack of maintenance and investment, significant labor cost) on the one hand, and the demands of the new "non carbon" era (CO_2 tax, lower demand) on the other hand put a significant strain on the coal mining industry. The government(s) plans to restructure the industry (merging coal mines and power plants, close too expensive mines, investment) and in this way save jobs. Additionally, the government(s) "push" for new thermal power plants has resulted in many new projects in the horizon. The new coal mines projects are closely connected with new thermal power plants projects.

The Framework Energy Strategy of Bosnia and Herzegovina until 2035 analyzed several different scenarios for the new power plants. Selection of one of the scenarios (power generation mix until 2035) is a discretionary decision of stakeholders at entity and State level in accordance with legal and regulatory obligations. It should be noted that a significant number of new thermal power plants are currently planned within the context of the Framework Strategy, but it is questionable how compatible they are with EU's energy policy.

According to the "most relevant" scenario ("entity scenario") the installed capacity in thermal power plants by 2035 will increase by 189% (compared to 2016). That means that 2.600MW in new thermal power plant capacity is planned, but meanwhile six (6) thermal power plant units are going to be decommissioned with total capacity of 926 MW. The time ahead will indicate whether the planned new "coal MWs" are realistic or over-optimistic. Figure 5.45 shows the anticipated changes (new power plants, decommissioning of existing power plants) in installed capacity in Bosnia and Herzegovina from 2016 till 2035.

Electricity

(a)Electricity supply and demand

A record in electricity generation amounting to 17.873 GWh was reached in the 2018, which was18.0% more than that generated in 2017. The production in 2018 was the result of the very favorable hydrological conditions during the year (65% higher production of HPP compared to 2017).

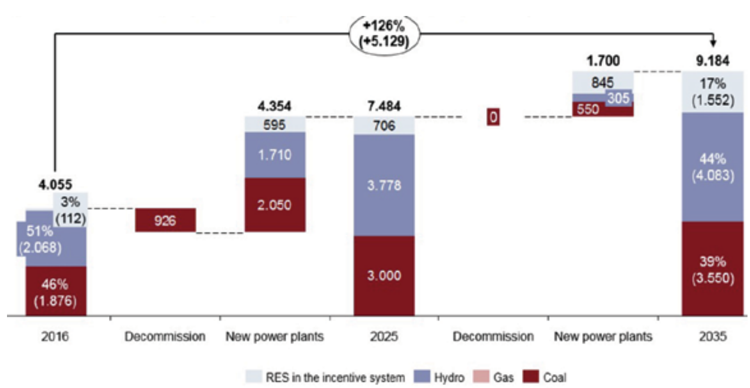
Total electricity consumption amounted to 13.294 GWh (2018) or 3,3% more than in 2016, but total electricity consumption in 2019 amounted to 12.330 GWh or 7,3% less than the previous year. This significant decline in electricity consumption was the result of the termination of operation of Aluminijum[10], the largest electricity consumer in Bosnia and Herzegovina (about 2.000 GWh/year).

(b) Installed Capacity

The total installed capacity of power generation units in Bosnia and Herzegovina in 2019 amounted to 4.508 MW, with 2.077 MW (46,1%) and 2.065 MW (45,8%) installed corresponding to large hydro power plants and thermal power plants respectively. During the period 2016-2019 there were some changes in the structure of installed capacity:

- TPP Stanari 300 MW (IPP[11]) started commercial operation (2016)
- Two wind farms (WPP Mesihovina (51MW) and WPP Jelovača (36MW)) also started commercial operation in 2018.

Figure 5.45 **BiH installed capacity by technology in MW, 2016 - 2035**



Source:Framework Energy Strategy of Bosnia and Herzegovina until 2035, 2018

[10] The termination of operation was due to business reasons (financial indicators, significant debts) with a very unfavorable chance of resuming aluminum production in the medium term.
[11] EFT Group is owner of TPP Stanari

Table 5.38 **Total installed capacity in Bosnia and Herzegovina (2019)**[12]

	2019 - Installed Capacity (MW)	% of Total
Thermal Power Plants	2.065	45,8%
Hydro Power Plants	2.077	46,1%
Wind Power Plants	87	2,0%
Small Hydro Power Plants	162	3,6%
Solar Power Plant	22	0,5%

[12] Annual report 2019, State of State Electricity Regulatory Commission in Bosnia and Herzegovina

(c) Electricity imports - exports

Looking at the balance of the electricity power system of Bosnia and Herzegovina during 2015-2019 (Table 5.39) it is evident that the country has been generating a surplus of electricity. Also, it is evident that, in average, this surplus is the result of the high share of coal in the electricity generation mix. Yearly variation of the above-mentioned electricity surplus is due to the impact of hydrological conditions ("dry" or "wet" year). The net export of electricity from Bosnia and Herzegovina in 2018 amounted to 4.579 GWh and represents an increase of 157% compared to the previous year. This difference is due to two hydrologically very different years.

(d) Electricity Prices

Since 1 January 2015, all customers in BIH have the possibility of choosing freely their suppliers. Customers that do not choose their supplier may be supplied by public suppliers (the role of the Reserve supplier) at public supply prices, while households and small customers may be supplied within the universal service at regulated prices. Network activities are fully regulated by regulatory commissions dependent on their jurisdictions:

- SERC regulates the whole transmission level (Tariff for ISO Operation, Tariff for the Services of Elektroprijenos BiH, Tariffs for Ancillary and System Services)
- Entity regulators regulate the distribution level (distribution network tariffs)

Electricity customers from the household category and other categories (voltage level of 0,4kV-small companies and commercial customers) who have not chosen their electricity supplier have the right for the supply of standard quality electricity, at economic transparent prices, within the scope of universal services offered from a public supplier. There is also the Reserve supplier, who has the obligation to supply the eligible electricity customer in periods no longer than 60 days, when the chosen supplier terminates /stops to supply the eligible customer. Public and Reserve suppliers of electricity in Federation BiH are appointed by the government of Federation BiH (public utilities (incumbents): Elektroprivreda BiH and Elektroprivreda HZHB).

Additional to price regulation for customers under universal service in RS there is some kind of generation regulation where RERS (the Entity Regulator) regulates the production of electricity. In this way, they maintain the price level of electricity for all customers in the RS independent of the market price.

Table 5.41 presents the average prices of electricity for end customers in Bosnia and Herzegovina by customer category. Prices are without VAT and renewables fee. It can be observed that for most of the customer categories there has been a price increase. The prices in 2019 increased from 8% to 20% compared to 2017. The exception is household tariffs where the price has not changed.

Table 5.41 **Average prices of electricity by customer category without VAT (EUR/MWh)**

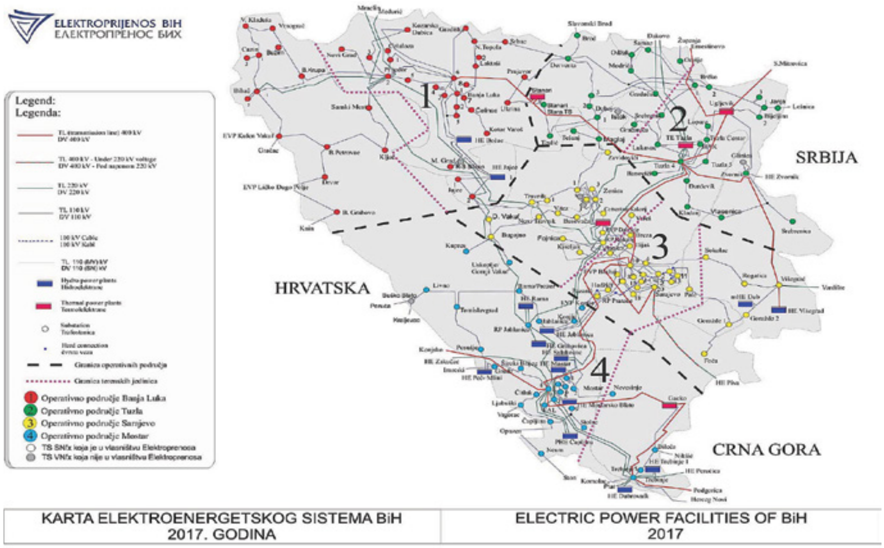
Category of customer	2017	2018	2019	2019/ 2017
110kV	42,44	48,57	50,77	120%
35kV	50,06	53,23	57,21	114%
10kV	59,00	9,92	63,91	108%
0,4kV Commercial	90,24	90,45	91,52	101%
Households	72,19	72,60	72,50	100%
Public Lighting	81,96	85,95	88,30	108%

Source: Annual report 2019, State of State Electricity Regulatory Commission in Bosnia and Herzegovina

(e) Cross-border interconnections

Elektroprijenos BiH is the owner of transmission network and the Independent System Operator of Bosnia and Herzegovina (ISO BiH) and is responsible for the operation of the transmission system of Bosnia and Herzegovina. Transmission network consists of over 6,400 km of overhead lines (400kV, 220 kV and 110 kV), 153 transformer stations and switchgears at 400, 220 and 110kV voltage levels with 12.783 MVA total installed capacity.

Map 5.7 **Map of electric power facilities of Bosnia and Herzegovina** [13]



Source: Elektroprijenos of Bosnia and Herzegovina, https://www.elprenos.ba/EN/MapeEN.aspx

(f) Planned new projects

The Framework Energy Strategy of Bosnia and Herzegovina until 2035 analyzed several different scenarios for new power plants. Selection of one of the scenarios, or power generation mix until 2035, is a discretionary decision of stakeholders of entities and the State in accordance with legal and regulatory obligations. According to the "most relevant" scenario ("entity scenario") the installed capacity will increase by 126% by 2035 (compared to 2016), i.e. 5.129 MW, including commissions and decommissions. It is planned that most of the new planned facilities (with a total capacity of 4,354 MW) will be put into operation by 2025. In the same period, six thermal power plants will be decommissioned with a total capacity of 926 MW. During the period of 2025 - 2035, another 1.700 MW of capacity will be commissioned, with no additional decommissions.

Figure 5.45 shows the changes (new power plants, decommissions of existing power plants) in installed capacity in Bosnia and Herzegovina from 2016 till 2035. Additionally, Tables 5.43 and 5.44 show a list of potentially new thermal and RES (including hydro) projects in Bosnia and Herzegovina, respectively, sorted by type.

During the previous years, and for various reasons, a significant number of new thermal power plants were planned in Bosnia and Herzegovina. From today's perspective, some of the planned power plants are not realistic, in view of increased competition, environmental constraints and the emphasis on RES following the EU Green Deal approach. Some of the plants did not follow the necessary procedures that precede the planning documents (studies, permits, financing issues). Due to all of the above, certain TPPs are still marked as "under preparation" or "under consideration" status.

According to the Indicative Generation Development Plan for 2020 - 2029 of the Independent System Operator of Bosnia and Herzegovina, new planned capacities for the period 2020-2029 are presented in Table 5.42.

Table 5.42 **New planned capacities in the period 2020-2029**[14]

[14] Indicative Generation Development Plan for the period from 2020. to 2029., Jun 2019, Independent system Operator of Bosnia and Herzegovina

Renewables

(a) Overview of sector's development (legislation, policies)

RES policy is in line with the administrative organization of Bosnia and Herzegovina. The general framework for a promotion of RES generated electricity is defined by Law on Usage of Renewable Energy Sources and Efficient Cogeneration (FBiH entity) and the Law on Renewable Sources of Energy and Efficient Cogeneration (RS entity). In this sense, the promotion system is administered by the RES Operators (in both entities).

In the Federation BiH (entity) the promotion system is administered by the RES Operators. The FBiH Government passed a Decision on Establishment of RES Operator, according to which the RES Operator in FBiH established. The FBiH RES Operator, inter alia, conducts the following activities: (i) concludes contracts on purchases of electricity at guaranteed prices and buys the total electricity produced from privileged producers; (ii) maintains the Register of guarantees and the Register of projects; and (iii) conducts the procedure for actually granting the status of a privileged producer to a potentially privileged producer. The promotion scheme generally depends on the classification of the producer of RES-Electricity (installed capacity and type of producers). All producers of RES Electricity have advantages concerning connection to the grid. "Privileged producers" have the right to sell all produced electricity under the feed-in tariff ("the Guaranteed price") for a determined period of time (12 years). A "Qualified producers" (producers have not obtained the status of the privileged producer or whose status of the privileged producer has expired) have the right to sell all produced electricity at the Reference price (The price is defined by the Regulator).

The status of a potential privileged producer can only be obtained if the required installed capacity of renewable energy generation within the allocated quota is available for a particular type of technology. The quota is the maximum level of installed capacity of the RES privileged producers whose production is subsidizes, and for each primary source of energy is determined by the Action Plan for Renewable Energy Sources of the Federation of BiH (APOEF).
The Law foresees that the quotas be allocated in the order of the entry of projects into the Project Register.

In Republic of Srpska (entity), the role of RES Operator is performed by the Public Utility Elektroprivreda RS. The promotion system includes: (i) benefits for the grid connection and access; (ii) mandatory repurchase of electricity; (iii) feed-in tariff; and (iv) premiums. In more detail, this includes:

- benefits when connecting to the grid, in terms of time and in certain cases the costs for analysis of connection to the grid;
- preferential access to the network (dispatching) provided by the system operator (limitation is made only for those producers of electricity which sell the electricity on the market);
- right to the repurchase of electricity for a determined period (15 years);
- feed-in tariffs;
- premiums for consumption of electricity for personal use or sale in the market.

In order to take advantage of the incentives, the RES producer in RS must obtain an RES certificate and a Decision on the right to an incentive. For the Decision it is necessary to submit an application to the Regulatory Authority. Subsequently, the Incentive System Operator (public utility) establishes a contract for the purchase of electricity by feed-in tariff, which varies depending on the size and technology of the plant or the premium. The Renewable Energy Action Plan of Republic of Srpska (RS Action Plan), adopted by the Entity Government, defines quotas for privileged producers, as well as tariffs. Feed-in tariffs and premiums are awarded according to the order of submission of the application to RERS, until the complete quotas set in the Action Plan are exhausted. It should be noted that the incentive is not granted to producers who embed used equipment in the plant. The main components for the production of electricity (generators, photovoltaic panels, boilers or turbines) must be new to be eligible for incentive.

(b) Feed-in tariffs

There are methodologies for the calculation of feed-in tariffs as well as criteria for anticipated changes. The respective rulebook is approved following consultation with the expert community and other relevant stakeholders, and takes into consideration criteria such as form of primary energy, the technology which is being used, installed power of the facility, starting date of operation of the facility, as well as the contracted term of repurchase.

In Federation BiH (entity) the feed-in tariffs consist of a tariff coefficient and a reference price. Accordingly, the Reference price as of 1 March 2019 was 55,64 EUR/MWh and is determined based on the previous twelve (12) month period by the Entity regulatory authority (FERK). The tariff coefficient is determined depending upon the type and size of the facility. The tariff coefficient used for the calculation of feed-in tariffs is adopted every eighteen (18) months. In Table 5.45 actual feed-in tariffs are presented (valid from March 2019).

Table 5.45 **Feed-in-Tarrifs for different RES installations (FBiH)**

Type of plant according to type of primary energy source	Capacity kW	Guaranteed price (FIT) from March 2019 EUR/MWh
Hydro Power Plant	**up to kW**	
a) micro	23	144,36
b) mini	150	88,91
c) small	1.000	66,68
d) middle	10.000	59,87
Wind Power Plant		
a) micro	23	186,86
b) mini	150	110,25
c) small	1.000	94,02
d) middle	10.000	79,61
Solar Power Plant		
a) micro	23	208,15
b) mini	150	115,88
c) small	1.000	93,12
Biomass Power Plant		
a) micro	23	154,82
b) mini	150	122,73
c) small	1.000	118,18
d) middle	10.000	111,22

Source: Calculation based on the Decision of the Government of FBiH from February 2019

In RS (entity) the feed-in tariffs are determined on the basis of a methodology prepared by the RERS (Entity regulatory authority). The feed-in tariffs consists of "a reference price" for mandatory sale of all produced electricity and a "premium". The values of feed-in tariffs are determined by the RERS with the approval of the RS Government. The RERS determines the amount of feed-in tariffs at least once a year and makes adjustments for the upcoming period if and where necessary. In Table 5.46 the actual calculated feed-in tariffs and premium values for 2019 are presented.

Table 5.46 **Feed-in-Tarrifs and premium values for 2019 (RS)**

Type of plant according to type of primary energy source	Premium EUR/MWh	Feed-in Tariff EUR/MWh
Hydro Power Plant	**up to kW**	
(a) up to 1MW	42,23	71,38
(b) from 1MW to 5MW	33,59	62,74
(c) from 5MW to 10MW	31,50	60,64
Wind Power Plant		
(a) up to 10MW	45,81	74,96
Solar Power Plant		
(a) up to 50kW (on the roof)	110,64	139,79
(b) from 50kW to 250kW (on the roof)	90,55	119,69
(c) from 250kW to 1MW (on the roof)	65,75	94,9
Solar (on land) up to 250kW	81,76	110,9
Biomass Power Plant		
(a) up to 1MW	94,23	123,37
(b) from 1MW to 10MW	86,46	115,6

(c) Installed capacity per source

"In 2017, Bosnia and Herzegovina achieved a 22,7% share of renewable energy in gross final energy consumption (Figure 5.47), way below the 37,9% median trajectory for 2017 - 2018. This is due to the downward revision of biomass consumption and limited investments in new renewable energy capacities." [15]

[15] Annual Implementation Report 2018/2019, Energy Community Secretariat, November 2019

Despite the significant delay in the implementation of defined targets, there is no significant official activity for a new approach in the foreseeable future. This has been addressed in the EnCS's Implementation Report 2018/2019. Activities towards the adoption of revised renewable energy laws that include a market - based approach for granting support, in line with Guidelines on State aid for environmental protection and energy 2014 - 2020, have not yet commenced in any entity.

(d) Planned new RES plants

Table 5.48 lists potential new RES generation projects (including hydro) in Bosnia and Herzegovina. From the listed projects the wind farms Podvelezje (48MW) is at an advanced stage of construction and WPP will be connected to the network by the end of Q2 of 2021. For other larger projects, there is still no reliable information on the status of realization.

Energy Efficiency and Cogeneration

(a) National targets

The main driver for the promotion of energy efficiency in BiH are the commitments under the Energy Community Treaty. Energy prices, especially for electricity and heating, are still relatively low compared to other European countries and do not provide strong incentives to save energy. In recent years, a number of public buildings have been renovated, but much work remains to be done in this field. Most existing buildings are in poor condition with high energy requirements. Although the implementation of energy efficiency measures has started with promising results, lack of funding remains a major bottleneck for the development of this sector.

According to the Energy Community Treaty commitments Bosnia and Herzegovina is required to transpose EU directives[16] into its energy efficiency legislation. Bosnia and Herzegovina legal framework for energy efficiency has been improved over the years, but is not yet at the required level. In the coming period, it is necessary to take a series of decisions and measures that not only transpose binding EU directives according to the obligations of the Energy Community Treaty, but would also fully enable their implementation.

The state-level National Energy Efficiency Action Plan (NEEAP), adopted by the Council of Ministers (State Government) in December 2017, includes forecasted energy savings and targets for primary and final energy consumption for Bosnia and Herzegovina, Federation Bosnia and Herzegovina, Republic of Srpska and Brčko District for 2020.

[16] Directive 2006/32/EU on energy end-use efficiency and energy services, Directive 2010/31/EU on the energy performance of buildings, Directive 2010/30/EU on the indication by labelling and standard product information of the consumption of energy and other resources by energy-related products, Directive 2012/27/EU on energy efficiency, which obliges contracting parties to much more stringent requirements that must be met in the field of energy efficiency

According to the NEEAP, the indicative target for savings in primary energy consumption in Bosnia and Herzegovina in 2020 is defined as follows: "By the end of 2020, primary energy consumption will be reduced by 12% compared to forecasted consumption without energy efficiency measures. In absolute terms, and in comparison, to the forecasted primary energy consumption of 8,031.98 ktoe without any energy efficiency measures, this amounts to 7,068.14 ktoe with implementation of planned energy efficiency measures or a reduction of consumption by 963.84 ktoe." [17]

The specific targets under the Energy Efficiency Directive are still not set (for renovation of central government buildings and the energy efficiency obligating scheme), but most of the activities have been finalized and are awaiting political decisions. The final energy efficiency obligation scheme model for Bosnia and Herzegovina was prepared and presented to stakeholders. In order to put this mechanism in place, Bosnia and Herzegovina should pass the necessary amendments to the entity Energy Efficiency Laws, formulate the calculation of methodologies and issue a regulation on the implementation of the scheme via implementing regulations or guidelines.[18]

(b) EU funded (or otherwise funded) energy efficiency programmes in the building sector

According to Energy Community Secretariat, the energy efficiency investment needs in the Western Balkans' buildings sector alone are probably in excess of €3 billion[19,20]. Most facilities rely on local financial intermediaries to identify and implement projects using funds provided by the facilities. Approximately 45 commercial banks or financial institutions offer energy efficiency or renewable energy financial products in the region. Many of their financial products are based on the offer of dedicated credit lines made available by international financial institutions and development banks, supported by EU grant funding for both technical assistance and financial incentives.[23]

Some of the them are listed below:

- Regional Energy Efficiency Programme (REEP and REEP Plus). Technical assistance and investment grants (EBRD, EU) [21]
- Green Economy Financing Facility (GEFF). Technical assistance and investment grants (EBRD) [22]
- Green for Growth Fund (GGF). Technical assistance and investment grants (EIB, KfW) [23]

Cogeneration

Like most other things in Bosnia and Herzegovina, cogeneration policies follow the administrative organization of Bosnia and Herzegovina. General framework defined by Law on Usage of Renewable Energy Sources and Efficient Cogeneration (FBiH entity) and the Law on Renewable Sources of Energy and Efficient Cogeneration (RS entity).

One of the key elements of the energy efficiency strategy as defined in the Framework strategy is the creation of conditions for highly efficient cogeneration as well as for the promotion and expansion of efficient district heating systems using waste heat, waste and renewable energy sources wherever possible and with economically viable terms. As one of 5 analyzed scenarios in the Framework Strategy is a "cogeneration scenario". A "cogeneration scenario" has not been deeply elaborated as other scenarios in the Framework Strategy because the scenario requires a very complex implementation and a number of conditions to be met so as to make the scenario sustainable in the long-term.

One of the larger projects under implementation (planned start of operation in 2021) is the one concerning the modernization of an on-site CHP plant at ArcelorMittal Zenica facilities (iron & steel making plant). The project will replace and modernize the existing CHP and provide sustainable source of power and heat for the City of Zenica and the Arcelor Mittal Zenica facilities, and will substitute the use of coal with the use of process gases from

[18] Energy Efficiency Action Plan in Bosnia and Herzegovina 2016 – 2018

[23] https://energy-community.org/regionalinitiatives/infrastructure/donors/Regional/GGF.html

the steelworks as fuel, and as a result achieve substantial reduction in CO_2 emissions, as well as improvement in dust content, NOx and SO_2 emissions. The CHP plant will have a power output of 14,45 MW and a heat capacity of 112,5 MW. [24]

Once it is commissioned in 2021, the new plant will produce all district heat for the city of Zenica as well as most of the energy needed in ArcelorMittal's steelworks.

Energy Investments Outlook

Actual major energy projects

Based on the latest news and information available to the public, the best estimate is made for the new energy projects from the Indicative Generation Development Plan[25] for the period from 2020 to 2029. In Table 5.48 "best estimation" of the indicative start of operation and status of the projects is presented.

Table 5.48 **RES installed capacity per source**

Type	Facility	Installed capacity (MW)	Estimated start of operation	Remarks
Hydro	HPP Ulog	35	2024	2024The EPC Contract, signed between EFT and Sinohydro Corporation Ltd (China), has entered into force on 20 December 2019.[26]
Hydro	HPP Vranduk	20	N/A	The project temporarily stopped due to unsuccessful negotiations on a settlement between Elektroprivreda BiH and Strabag (the contract terminated because parties did not agree with an additional works and payments on the project [27]). The start of the process at the International Court of Arbitration is expected. Further implementation of the project is uncertain.
Coal	TPP Tuzla 7	450	2026	Both houses of the FBiH Parliament approved (April 2019.) the proposed decision for the Federation of BiH to provide guarantees to Elektroprivreda BiH for a loan from the Export-Import Bank of China for the construction of Unit 7 in TPP Tuzla. The EPC contract was signed with China Gezhouba Group. Preparatory works on the construction of Unit 7 started on November 1st 2019.
Wind	WPP Podveležje	48	2021	The WPP id under construction. Elektroprivreda BiH has completed works on the construction of a transformer station and medium-voltage cable network. [28]
CHP	CHP ArcelorMittal Zenica [29]	14+112 (heat)	2021	The plant will produce all district heat for the city of Zenica as well as most of the energy needed in ArcelorMittal's steelworks. Project is under construction and start of operation is expected in 2021.[29]

5

BULGARIA

Bulgaria

Economic and Political Background

Bulgaria's GDP fell at a more moderate pace of 3.8% in the fourth quarter of 2020, above the 5.2% contraction tallied in the third quarter, amid the gradual firming of activity. On a seasonally-adjusted quarter-on-quarter basis, growth slowed to 2.2% in Q4 2020 from 4.3% in the previous quarter. Taking the year as a whole, the country's economy contracted 4.2% in 2020 (2019: +3.7%), marking the first decline in activity since 2009.

The fourth quarter's annual result largely came on the back of an improvement in the external sector. Exports of goods and services declined at a slower pace of 11.2% year-on-year in Q4 (Q3: -20.8% y-o-y). In addition, imports of goods and services fell 0.8%, moderating from Q3's 4.3% fall.

On the domestic front, total consumption growth eased to 0.9% in the fourth quarter from 2.7% in Q3. Meanwhile, fixed investment contracted at a sharper rate of 7.4% in Q4 2020, compared to the previous quarter's 6.4% decrease. IMF estimates that Bulgaria's GDP will expand by 4.1% in 2021, significantly higher than -4.0% in 2020.

General Parliamentary elections were held in Bulgaria on April 4, 2021. The results showed that the ruling right-wing party GERB again won the most votes and came out on top in the rankings. However, the future government is extremely unclear, as GERB does not have a majority to form an independent government. According to the election results, in the parliament enter five other parties and coalitions that have previously declared themselves in opposition to the ruling party so far with its leader Boyko Borissov.

On a second place with the most votes in parliament enter a completely new party called "There is such a people", created by the famous showman, TV presenter and singer Slavi Trifonov which has a categorical position that it will not form a coalition with any of the parties that have been present in the parliament so far – GERB, the Bulgarian Socialist Party and the Movement for Rights and Freedoms (MRF; primarily representing the country's Turkish minority).

The biggest loss in these elections was suffered by the Bulgarian Socialist Party, which became the third political force and lost much of the support of its voters and respectively its influence in the parliament.

Energy Policy

Oil and Petroleum Products

A basic document for national energy policy in Bulgaria is the Energy Strategy (ES). The current ES was approved by the Council of Ministers and was voted through by the National Assembly of Bulgaria on June 01, 2011.

Based on the European targets "20-20-20 to 2020", the ES covers a horizon to 2020 and is designed to meet the main challenges faced by the Bulgarian energy sector. Namely: high energy intensity of GDP, high dependency on energy imports and the necessity for environmentally sound development. On that ground the main priorities in the ES are:

- to guarantee the security of energy supply;
- to attain the national targets for renewable energy;
- to increase energy efficiency;
- to develop a competitive energy market and
- to adopt policies for ensuring the energy needs;
- to protect the interests of consumers.

ES outlines specific sectoral policies and measures such as: diversification of the sources and routes for natural gas supplies (incl. support for indigenous resources exploration and exploitation), promotion of household gasification, cost efficient and sustainable achievement of the national 16% RES target, strong support for sound energy efficiency improvements along the entire energy chain of "production, transmission and consumption", sustainable development of centralized district heating, establishment of a competitive and integrated national energy market for electricity and natural gas.

In addition to the ES, in 2020 the government has adopted "an Integrated Energy and Climate Plan" in accordance with the Regulation on the governance of the energy union and climate action (EU)2018/1999, agreed as part of the Clean energy for all Europeans package which was adopted in 2019. Some of the main goals of the National Plan include:

- Achieve 27.09% of RES contribution to final energy consumption by 2030;
- Aim for a 27.89% decline in primary energy consumption in 2030 compared to 2007 and a 31.67% decline in final energy consumption;
- Aim for 0% decline in greenhouse gas emissions in 2030 compared to 2005;
- Achieve a 15% interconnection capacity of the electricity system.

In addition, the government envisages the adoption of a new Energy Strategy with a scope to 2030 and a horizon up to 2050. A draft of the Strategy is yet to be published and circulated for public consultation.

Governmental institutions

The National Assembly (NA) adopts the national ES and the main energy legislation, (energy law, law on energy from renewable sources and law on energy efficiency, etc.).

Within the Council of Ministers there are three ministerial bodies which are in charge of different aspects of national energy policy, in accordance with the adopted by NA energy legislation and ES. The Ministry of Energy (ME) is responsible for the implementation of the agreed national energy policy, and holds the main responsibilities for the implementation of the state energy policy and exercising ownership rights over state energy companies. The Ministry of Environment and Water has the responsibility for Climate Change and environmental protection policy while the Ministry of Regional Development and Public Works have particular responsibility on some residential and public energy efficiency programmes.

The Ministry of Economy is responsible for the implementation of government policy on building a competitive low-carbon economy, promotion and acceleration of investment, innovations and competitiveness.

The Sustainable Energy Development Agency is an executive agency within the ME, responsible for the implementation of state energy efficiency and RES policy.

The Energy and Water Regulatory Commission (EWRC) is the national regulatory authority for energy. Its main responsibilities are price setting, licensing & supervision, market monitoring. The Nuclear Regulatory Agency is the independent specialized authority, responsible for the state regulation of the safe use of nuclear energy and ionising radiation, the safety of radioactive waste management and the safety of spent fuel management.

Energy Demand and Supply

National energy demand

The Gross Inland Energy Consumption (GIC) has shown a steady increase in recent years and reached 19 mtoe in 2018 after decreasing to 16.8 mtoe in 2013, which was the statistical lowest level since 1990. Up until 2013, the dynamic was mainly driven by the stagnating economic growth due to lower external demand for Bulgarian goods, coupled with an internal political crisis. Economic growth started to pick up pace in 2014 and GIC followed shorty.

Typically for the country, the average ratio between Final Energy Consumption (FEC) and GIC is about 50%. Half of the energy is therefore lost in the transformation processes and the energy system's own use. Thus, there is a large potential for improvement after taking structural and efficiency measures, both on the production as well as on the consumption side. For comparison this ratio for the EU was 63.5% in 2018. However, it should be pointed out that Bulgaria's ratio has been increasing in the past couple of years and reached 51.4% in 2018.

As a result of the economic crisis, the FEC moved to its lowest level of 8.6 mtoe in 2009, followed by a slight recovery and stabilization in the next two years, although it has remained almost stagnant until 2014. Increasing economic growth in the past years has driven FEC in 2018 by almost 10% compared to 2014.

Table 5.49 **Energy Consumption (mtoe), 2014-2018**

	2014	2015	2016	2017	2018
Gross Energy Inland Consumption, (mtoe)	17.9	18.7	18.3	18.9	19.0
Final Energy Consumption (mtoe), incl. by sector	8.9	9.4	9.5	9.7	9.7

Agriculture	0.2	0.2	0.2	0.2	0.2

Source: Eurostat

National energy supply

The levels of primary energy consumption and energy imports were almost equal during the above period, although there have been exceptions e.g. 2016-2017. The proportion between primary energy production and energy imports varies substantially for the different resources. The local production of solid fuels is about 80% of the energy supply while the imports are 20% and correspond to oil and gas. Oil and natural gas imports are respectively 100% for crude oil supply and around 94% for the gas supply. Russia provides 100% of the imported gas and about 80% of crude oil.

During the above period the primary energy production has somewhat decreased from its all-time high of 12.3 mtoe in 2011 mainly due to lower production of solid fuels, mostly lignite. Solid fuels are used mainly for power generation needs. Energy imports, increased significantly in 2015-2017, and returned to average levels in 2018. Energy exports mostly electricity, remained relatively high in 2014-2017 and, in 2018, declined to their levels from 2010-2011.

Table 5.50 **Energy Supply, mtoe, 2014-2018**

	2014	2015	2016	2017	2018

Renewable energy	1.9	2.1	2.0	1.9	2.6

Source: Eurostat

Energy mix

Bulgaria's energy mix appears well diversified since the country uses a wide variety of energy sources. Moreover, around 65% of the country's needs are covered by sources that are almost entirely domestic: solid fuels, renewables and nuclear.

Table 5.52 **Gross inland energy consumption by fuel type, mtoe, 2014-2018**

	2014	2015	2016	2017	2018
Gross Energy Inland Consumption, (mtoe)	17.9	18.7	18.3	18.9	19.0
Solid fuels	6.4	6.6	5.7	6.1	5.6
Total petroleum products	4.0	4.3	4.3	4.5	4.6
Natural gas	2.4	2.6	2.7	2.8	2.6
Nuclear heat	4.0	3.9	4.0	3.9	4.2
Renewable energy	1.9	2.1	2.0	2.0	2.5
Waste (non-renewable)	0.0	0.0	0.0	0.0	0.1

Source: Eurostat

Although oil products were reduced in the FEC during 2010-2013, they still account for the largest share in the FEC, which has been increasing in recent years and reached 36% in 2018, compared to 32.3% in 2013. Although renewables and waste (biomass) steadily increased their share in FEC during 2010-2013 their share stagnated during 2014-2018. One of the main reasons is that the country reached its 2020 target in 2013, after which subsidies for new RES installations were almost completely suspended.

Table 5.53 **Final energy consumption by product, mtoe, 2014-2018**

	2014	2015	2016	2017	2018
FEC by product	8.9	9.4	9.5	9.7	9.7
Solid fuels	0.3	0.3	0.3	0.4	0.4
Total petroleum products	2.9	3.2	3.2	3.4	3.5
Electricity	2.4	2.4	2.5	2.6	2.6
Natural Gas	1.2	1.3	1.3	1.4	1.3
Heat	0.9	0.8	0.8	0.7	0.5
Renewable energy	1.2	1.3	1.3	1.4	1.4

Source: Eurostat

Energy dependence

The energy dependency of the country over the last four years has fallen as low as 35.5% in 2014. It has increased in the following years up to 36.4% in 2018, however, it remains significantly lower than the EU average. Bulgaria has a high dependency on energy imports from Russia, concentrated in two energy sources: crude oil and natural gas. Improvement of the energy dependency indicator depends on local coal production and nuclear energy, which are considered as local resources.

Table 5.54 **Energy dependence, 2014-2018**

	2014	2015	2016	2017	2018
Energy Dependence	35.2	36.4	38.5	39.4	36.4

Source: Eurostat

According to the National Energy and Climate Plan 2021-2030, the results of the projections with existing measures are the following:

1. A decrease of GIC from 19.1 mtoe in 2020 to 18.4 mtoe in 2030;
2. A negligible increase of FEC from 10 mtoe in 2020 to 10.4 mtoe in 2030

These favourable deliverables and the separation of GDP growth from the energy growth could be achieved through the ambitious goals for energy efficiency improvement and a reduction of energy intensity by an annual 2.6% during the period 2020-2040.

Oil and Petroleum Products

(a) Oil Supply and Demand

Crude oil participated with an almost negligible share in primary energy production. However, oil is among the main sources of energy used in Bulgaria, with stable presence in GIC, at around 23.5% for the period 2014-2018, as it represents the main energy source for transportation.

Table 5.55 **Crude oil supply, mtoe, 2014-2018**

	2014	2015	2016	2017	2018
Crude oil production	0.0	0.0	0.0	0.0	0.0
Import	5.2	6.2	6.3	7.0	6.0
Export	0.0	0.0	0.0	0.0	0.0
GIC crude oil	5.2	6.1	6.4	6.9	6.0

Source: Eurostat

Petroleum products participated in FEC with the highest share of 32-36% over the above period. Traditionally, the main consumer of petroleum products is the transport sector, particularly road transport, with a share of about 83-87% in FEC.

Table 5.56 **Final energy consumption of petroleum products, mtoe, 2014-2018**

	2014	2015	2016	2017	2018

(b) Oil Imports / Dependence

The country is entirely dependent on imports for the supply of crude oil. The major trading partners are Russia and Ukraine, which combined amount to more than 90% of the country's total imports and hence, the geographical diversification of oil supplies is rather limited. The rest of the oil supplies are imported from: Malta, Turkey, Kazakhstan, Egypt. The degree of petroleum products energy dependence is among the highest in the EU. The indicator has remained broadly stable during 2014-2018 with negligible fluctuations.

Table 5.57 **Energy dependence of total petroleum products (%), 2014-2018**

	2014	2015	2016	2017	2018
Energy dependence of total petroleum products	99.0%	100.5%	99.0%	101.1%	99.5%

Source: Eurostat

(c) Upstream Sector - Domestic Production and Exploration

There is not any significant oil production from indigenous sources in Bulgaria.

(d) Downstream and Midstream Sectors Infrastructure (Refineries, Pipelines, Storage, Terminal and Domestic Oil Market)

Refineries

The main oil refinery in Bulgaria and one of the biggest in the Balkan peninsula is owned by Lukoil Neftochim Burgas AD and is located in Burgas. It has a primary processing capacity of 9.5 Mt of crude oil per year and supplies liquid fuels, petrochemicals and polymers, being among the leading suppliers of petroleum products in the Balkan region and also distributes motor fuels to the rest of Europe & USA. There are three other manufacturers of petroleum products - "Bulgarian Oil Refinery" EOOD, "INSA Oil" Ltd. and "Polisan" AD.

Pipelines, terminals, storage facilities

Oil is imported through Bulgaria's main port at Burgas, where both the oil terminal and refinery are connected by pipeline to several Bulgarian cities. Physical storage and movement of fuel from the refinery and importers to the retail market and to end-users is done through largescale storage infrastructure and logistics.
Lukoil is the sole company which owns and operates all pipelines, serving the geographical area from Burgas to Sofia with a branch to Asparuhovo, Varna. The pipeline is intended for the fuel supply of the domestic market only and is not connected to the neighbouring countries. In addition to the pipeline, the logistics system of Lukoil Bulgaria EOOD includes a well-developed

transport system for the wholesale supply of fuels through the use of railway transport, covering the territory of the country and even distribution to warehouses and infrastructure for retail sales in key cities. Thus the physical flow of fuel throughout the country is achieved.

Domestic market

The market is fully liberalized and all downstream oil trading companies in Bulgaria are privately owned. The market is highly competitive, where small market players also have a share. The previously state-owned downstream oil company Petrol AD was privatized in 1999. The biggest players in the market either operate their facilities themselves (gas stations), or assign them to operators or franchisees.

The volumes on the wholesale market are traded by companies that are also suppliers of petroleum products. Typically, this activity is carried out directly or through other companies that perform the role of midstream players. Imported or domestically produced quantities reach the retail market (end users), either directly or through the channelling of products in the wholesale market. The customers in the wholesale market purchase products from tax warehouses (also known as excise warehouses) for storage (storage facilities); it is mandatory for imported fuels to be unloaded and stored in these tax warehouses before they enter the retail market. Tax warehouses enjoy a special tax regime and are under the control of the Customs Agency as they are in charge of collecting excise duties, while the National Revenue Agency is in charge of other taxes such as VAT, income taxes, social and health insurance benefits, etc. The most important market players are: Lukoil, Petrol, OMV, Shell, Naftex, Prista Oil, Hellenic Petroleum, Rompetrol, NIS Petroleum (Gazprom), Eco Bulgaria, Bulmarket DM, Vitogaz, Kalvacha Gas, Synergon Petroleum, Gastrade, INSA Oil.

The major player on the wholesale market is Lukoil Bulgaria, which is the biggest trader in the market. The company is vertically integrated with a refinery, petroleum products pipeline infrastructure, wholesale and retail suppliers, and located within the boundaries of the national market. The company also, directly or indirectly, owns over 80% of the capacity of tax warehouses for storing gasoline and diesel fuels. Traders on the wholesale market, other than Lukoil, include Rompetrol, Naftex Petrol, OMV Bulgaria, and Eco Bulgaria, which engage in imports from neighbouring refineries located in Romania and Greece.

(e) Security of Supply

The state controlled State Reserve and War-Time Stocks Agency maintains, in compliance with the relevant EU Directive Obligation, oil stocks in Bulgaria equivalent to 90-days average local consumption.

(f) Planned New Projects

Bulgaria's plan to participate in projects for the construction of crude oil pipelines such as the Burgas-Alexandroupolis and AMBO have dragged in time. In December 2011, the Bulgarian government withdrew from the Burgas-Alexandroplis project as a result of protests and a local referendum, on environmental grounds. The development of the second project - AMBO - was also suspended. The failure of these two projects is likely to reduce the country's ability to access alternative sources of crude oil over the coming years.The availability of an oil processing infrastructure and the country's ability to transport and distribute petroleum products in stable volumes, as well as the large investments in its expansion and modernization, offer grounds for optimism both in terms of security and future market development. This forecast is further supported by the current full liberalization of the oil market, ensuring the free movement of energy flows and products.

The transport sector, especially road transport, in Bulgaria is responsible for almost the entire FEC of petroleum products. Considering the lack of policy on energy efficiency improvement in the transport sector, no change should be expected in oil demand trends for the foreseeable future[1].

1 The WEM scenario projects an almost constant consumption of oil products in the period 2020-2030.

Natural Gas

(a) NG Supply and Demand (in bcm)

Natural gas had an almost constant share of just under 14% in Gross Inland Consumption during the period of 2014-2018. Electricity and heat generation were responsible for 32% of natural gas use. The non-energy use of natural gas in chemical industry accounted for around 8% of gross inland consumption of natural gas.

FEC natural gas consumption had been declining since 2011 due to the lower demand by the industrial sector. However, with economic activity picking up pace in 2014, FEC has increased slightly in recent years. Only 3.5% of the natural gas is consumed by households.

Table 5.58 **Natural gas demand, mtoe, 2014-2018**

	2014	2015	2016	2017	2018
GIC natural gas	2.4	2.6	2.7	2.8	2.6
Power Generation	1.2	1.3	1.3	1.4	1.3
Industry	0.8	0.9	0.9	0.9	0.9
Transport	0.2	0.2	0.2	0.2	0.2
Households	0.0	0.1	0.1	0.1	0.1
Services	0.1	0.1	0.1	0.1	0.1

Source: Eurostat

Bulgaria has been producing natural gas from its continental shelf in the Black Sea since 2001. The increase of local production in 2011 and 2012 follows the development of new fields in Kaliakra and Kavarna, however, in recent years production has been declining. A small part (1-3%) of the inland consumption of natural gas is covered from local sources. The country relies mostly on natural gas imports to meet its domestic demand.

Table 5.59 **Natural gas supply, mtoe, 2014-2018**

	2014	2015	2016	2017	2018

Export	0.0	0.0	0.0	0.0	0.0
Stock Changes	0.0	0.0	0.0	0.0	0.0
Gross Inland Consumption	2.4	2.6	2.7	2.8	2.6

Source: Eurostat

(b) NG Imports (in bcm)

The sole exporter of natural gas to Bulgaria is Russia. Bulgaria also acts as a transit route for Russian gas destined for Turkey, Greece and North Macedonia. Natural gas imports were almost stable during 2014-2018, albeit higher than compared to 2010-2013. The import of natural gas is based on long term "take-or-pay" contracts between Bulgargaz (Bulgaria) and RAO Gazprom (Russia) and covers exclusively inland consumption needs. The latter was abolished as part of commitments related to the European Commission's antitrust «CASE AT.39816 - Upstream gas supplies in Central and Eastern Europe».

(c) Dependence (%)

Being nearly 100% dependent on gas imports from Russia via a single route, Bulgaria continued to be vulnerable to gas supply disruptions over the period 2015-2019. The realization of new interconnection projects with neighbouring countries is likely to contribute both to the diversification of routes and, partially, suppliers over the next 5 years.

Table 5.60 **Energy dependence of total petroleum products (%), 2014-2018**

	2014	2015	2016	2017	2018
Energy dependence of natural gas	94.1%	97.0%	96.5%	97.6%	98.7%

Source: Eurostat

(d) Domestic Production and Exploration

Currently there are thirteen concession contracts[2] for gas exploration and production. The gas fields are located mainly on the north and north-east of Bulgaria. The main exploration and production companies are Melrose Resources, Oil and Gas Exploration and Production, and Direct Petroleum. The map below illustrates the current oil & gas exploration fields in Bulgaria.

[2] Concession Register of Bulgarian Ministry of Energy

Map 5.8 **Current oil & gas exploration fields in Bulgaria**

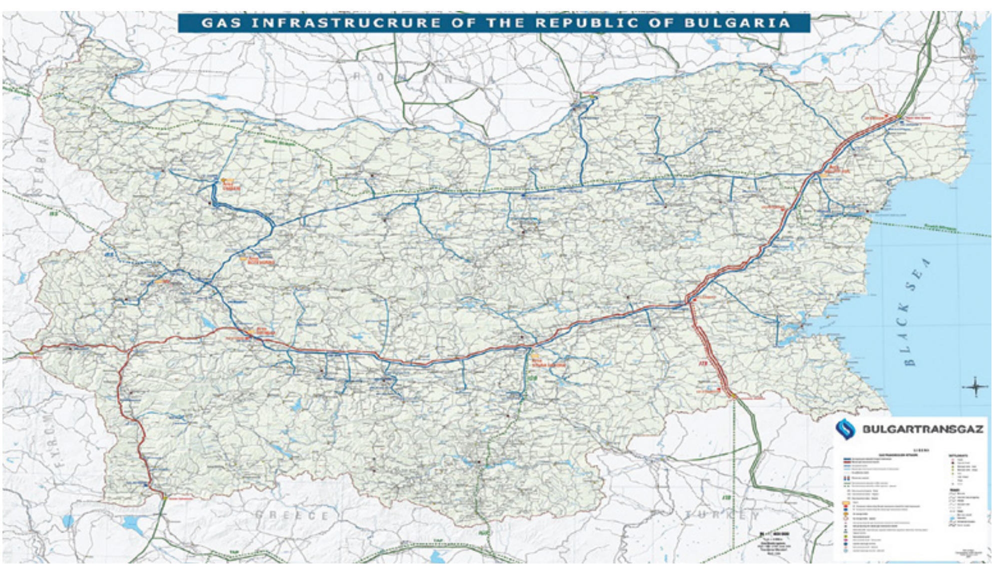
Source: Ministry of Energy

(e) Infrastructure (Pipelines, Storage)

The national gas transmission network is built in a ring-shaped form consisting of high pressure gas pipelines with a total length of 1700 km and three compressor stations with installed capacity of 49 MWt. Its technical transport capacity amounts to 7.4 bcm/year, and the maximum working pressure is 54 bar. The transit gas transmission network comprises high pressure gas pipelines of 945 km total length, six compressor stations with total installed capacity of 214 MW.

The total technical capacity for natural gas transit transmission amounts to 18.7 bcm/year and the maximum working pressure is 54 bar.The underground gas storage Chiren, is located near the city of Vratsa. It consists of 22 exploitation wells, a compressor station with an installed capacity of 10 MW and other equipment required to secure the injection, withdrawal and quality of stored gas. The development of low pressure gas distribution network in Bulgaria started in the last decade and its length is currently over 3,500 km.

Map 5.9 **Current gas infrastructure in Bulgaria**



Source: Bulgartransgaz

(f) Domestic Gas Market

Bulgartransgaz is the owner and operator of the national gas transmission network and of the Chiren single underground storage. Bulgartransgaz is also responsible for the administration of the natural gas market and balancing market under Natural Gas Trading Rules. The company is a 100% subsidiary of the state owned Bulgarian Energy Holding (BEH) and is under process of certification as an independent transmission operator under the Energy Law, transposing the requirements of Gas Directive 2009/73/EC.

Bulgargaz, which is a subsidiary of the BEH, is a single supplier and a public provider of natural gas for the whole country. Although there are rules and procedures stipulating the free access to the national grid, there have not been companies taking advantage of this facility.

In January 2019, the Gas Hub Balkan EAD company was established by Bulgartransgaz EAD (the state-owned Natural Gas Transmission System Operator) in line with the implementation of the concept for establishing a gas distribution center in Bulgaria. Furthermore, the company has started stock exchange trading in December 2019. The company operates trading platforms for the needs of the natural gas markets within the Balkan Gas Hub. In synergy with the physical infrastructure of the gas distribution center, the company provides the necessary prerequisites for the construction of the first liquid physical and commercial gas hub in the region of Southeast Europe, based in Bulgaria.

Gas distribution is performed by private regional and local companies, which perform licensed activities of gas distribution and supply for final consumers, connected to the gas distribution grids. However, Bulgaria's gas distribution network is not well developed with about 17% of natural gas consumption corresponding to customers of the distribution companies[3].

[3] Editor's note: Please clarify

(g) National NG Policy -Strategic Plan, Planned new projects

Diversification of sources and routes for the supply of natural gas is important for the country's energy security and independence. According to the ES (2011) the country will strive to build reverse interconnections with Greece, Turkey, and Serbia and will look into possibilities for the extension of the existing gas storage at Chiren, as well as for building of a new storage facility in Galata. There is already an interconnection with the Romanian transmission system, established in 2016, but the compression station on the Romanian side is still to be put into operation. The National Energy and Climate Plan 2021-2030 has the same goals as the ES.

The interconnections with Greece and Serbia, as well as increasing Chiren's capacity are included in the list of EU Projects of Common Interest (PCI) and have received grant support for feasibility studies and construction works under the European Energy Programme for Recovery, the European Fund for Regional Development and the Connecting Europe Facility. Bulgaria, via its transmission system operator, secured a 20% share in the LNG terminal at Alexandrupolis - another PCI project. Gas Hub Balkan was developed with the assistance of the European Commission and envisages the construction of a natural gas distribution center on the territory of Bulgaria, including the necessary gas transmission infrastructure, and an energy exchange for natural gas trade. The gas distribution center will connect the natural gas markets of Hungary, Croatia, Slovenia and through them the Member States of Central and Western Europe and the countries of the Energy Community - Serbia, Northern Macedonia, Bosnia and Herzegovina.
It is expected that through the implementation of ongoing or forthcoming projects aiming at diversification of routes and sources of gas supply (participation in transnational gas corridors, interconnectors with the neighbouring countries and access to LNG terminals and storages), continuing development of production from domestic reserves and energy security of domestic consumers will be guaranteed.

A priority of the ES and the National Energy and Climate Plan 2021-2030 is the development and extension of households' gasification. On the one hand, this will increase gas imports, increasing gas dependency, but on the other hand, higher use of natural gas will improve the energy efficiency ratios as less energy will be lost in transformation processes.

Solid Fuels

(a) Supply and consumption

The local production of solid fuels varied between 97-99% of the Gross Inland Energy during 2015-2019. Due to the high production and import requirements the supply of solid fuels reached its highest level in 2011 (since 1991) and has declined gradually in the last five years to 28.7 Mt, which is close to its 2010 level.

Table 5.61 **Solid fuels supply, Mt, 2010-2014**

	2014	2015	2016	2017	2018
Production	36.8	32.5	35.5	31.2	28.7
Import	1.1	0.9	1.0	0.9	0.6
Export	0.0	0.0	0.0	0.0	0.1
Stock changes	0.0	-0.1	-0.7	-0.4	-0.1
GIC solid fuels	37.9	33.3	35.8	32.0	29.5

Source: Eurostat

The majority of coal is used in the power sector with over 97% consumption and the rest is used for household heating and small industrial consumers. Environmental problems driven by the use of solid fuels for power generation are the main challenges facing solid fuels. Coal burning thermal power plants are responsible for emitting approximately 80% of national emissions of sulphur oxides and about 60% of carbon dioxide.

Table 5.62 **Solid Fuels Consumption, Mt, 2014-2018**

	2014	2015	2016	2017	2018
GIC solid fuels	37.9	33.3	35.8	32.0	29.5

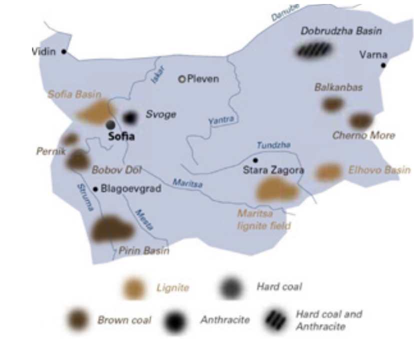
Source: Eurostat

Opencast lignite mining is carried out in the state owned mine of Mini Maritsa Iztok EAD, whose production amounts to approximately 95% of the total inland lignite output. The transportation of lignite over long distances is not considered profitable. Five large lignite fired plants operate adjacent to the Mini Maritsa Iztok lignite mine. There are some other smaller and privately owned local lignite mining companies. Production of brown coal corresponds to approximately 7% of total indigenous production. This production is mainly concentrated in the Western part of the country.

Map 5.10 **Distribution of coal reserves in Bulgaria**



Source: Eurocoal

Table 5.63 **Solid fuels production, Mt, 2015-2019**

	2015	2016	2017	2018	2019
Lignite & brown	35.9	31.2	34.3	30.3	28.0

Source: Eurostat

(b) Deposits

The proven geological lignite and brown reserves which are economically and technically exploitable in the short to medium term according to Euracoal for 2017, are respectively 2,174 Mt and 192 Mt. The entire amount of estimated lignite reserves, which are not economically and technically minable, amount to 4,574 Mt.

Table 5.64 **Coal resources and reserves, Mt, 2017***

Resources hard (black and brown) coal	4112
Resources lignite	4574
Reserves hard (black and brown) coal	192
Reserves lignite	2174

* Hard coal production is not significant (c.35 thousand tonnes) and is carried out by MINA BALKAN 2000 EAD

Source: Eurocoal

(c) Coal imports

Since 2010 the share of imports in solid fuels supply decreased from 10% to 5%. About 5% of the generated electricity comes from imported thermal coal. This trend has continued during the period 2015-2019, and the share of imports in 2019 reached 2.1%. The main reason is that the power station which uses imported thermal coal closed in the begging of 2015 due to environmental concerns. It reopened in 2018, however, with reduced capacity, mainly for providing a so-called cold reserve, through its natural gas-fired boilers. The environmental reasons have not been overcome, meaning that any increase in the producer's capacity will most likely be dependent on natural gas, rather than importing hard coal.

(d) Planned new projects - Coal Production Outlook

The future of local coal production depends on the development of the electricity generation, based on coal. Faced with the challenges of sustainable EU low-carbon policy, the coal production will depend on the competitive positions of coal-fired power plants in the country. Carbon Capture and Storage (CCS) technologies create prospects for this type of electricity generation, but currently they exist only at demonstration level, since they are not yet in commercial use.

Coal-fired power plants are even now struggling with high prices of CO_2 allowances and will be further hit by new environmental requirements to emission caps. The WEM (NECP) projects the reduction of the generation from coal of around 25% (with respect to the value of 2020), and to almost phase out coal-fired generation by 2040 (-90% with respect to the value in 2020).

Electricity

(a) Electricity Supply and Demand (TWh)

Bulgarian gross electricity generation reached 49.2TWh in 2015, which has declined in the following years below its 2012-2014 levels. Gross inland consumption also shrank to 33.6 TWh or about 75% of the gross electricity generation.

Although exports comprise a considerable part of gross electricity generation, their share has decreased from 30% in 2015 to 20% in 2019.

Table 5.65 **Gross electricity generation, Twh, 2015-2019**

	2015	2016	2017	2018	2019
Gross electricity generation	49.2	45.3	45.6	46.8	44.2
Import	4.3	4.6	3.7	2.2	3.0
Export	14.8	10.9	9.2	10.0	8.9
Net supply (generation + import - export) before losses	33.4	33.8	34.9	34.5	33.6

Source: Eurostat

The final electricity consumption has been increasing from 56% of the gross inland consumption in 2015 to 68% in 2019, however, it remains below its level during 2010-2013 of 77%.

The business and public sector consumption corresponds to about 63% of the final electricity consumption of the country.

Table 5.66 **Final electricity consumption, TWh, 2014-2018**

	2014	2015	2016	2017	2018
Final energy consumption, including	27.7	28.3	28.9	29.9	29.9
Business and public sector	17.1	17.7	18.2	18.8	18.9
Households	10.6	10.6	10.7	11.1	11.0

Source: Eurostat

(b) Installed Capacity

Although fossil fuels continued to cover a significant part of the generating capacities of the country, they were slightly losing their position during the period of 2010-2014 due to the rise of renewable energy sources. This process was further exacerbated by the increased prices of CO_2 allowances and the declining share of free allowances allocated to thermal plants. Fossil fuel capacity has stabilized at around 44% of total generating capacity in the last five years.

Although 2012 was a remarkable year for solar power development when the total installed capacity increased almost seven-fold, making Bulgaria a world leader in new solar capacity per GDP and per capita. RES capacity installations have stalled since 2013 following social unrest related to preferential pricing, attainment of the 2020 RES target, as well as unstable investment environment. It is reasonable to expect a renewed interest in RES investment due to replacements of older generating installations as well as new stimuli that can be introduced in order for the country to meet its 2030 RES target.

Table 5.67 **Generating capacity MW, 2015-2019**

	2015	2016	2017	2018	2019
Fossil fuels	5,706	5,683	5,048	5,468	5,713
Nuclear	2,000	2,000	2,000	2,000	2,000
Hydro	3,198	3,204	3,204	3,208	3,211
Renewables, incl.	1,806	1,813	1,821	1,826	1,833
Solar PV	1,041	1,043	1,046	1,052	1,059
Wind	701	701	701	700	700
Biomass	64	69	74	74	74
Total	12,710	12,700	12,073	12,502	12,757

Source: ENTSO-E Transparency Platform

(c) Planned New Capacity

In the recently updated Ten-Year Network Development Plan 2020-2029 the Bulgarian Electricity System Operator forecasted between -2.3% and 6.9% higher electricity consumption by 2029 compared to 2019 and a potential for electricity exports at around 100-300 MWh, which is a considerable setback compared to the Development Plan 2015-2024 envisioning experts of around 10 TWh.

Over the next 10 years the Electricity Transmission System Operator does not envision a change in the Nuclear Power Plant installed capacity, meaning that no new projects, such as NPP Belene or a new generation at the Kozloduy plant, can be expected. Thermal power plant net capacity is expected to decline by 63%, while gas-fired net capacity is projected to increase by 25%.

The largest increase is expected in RES net capacity:

• Biomass: 2020 - 80 MW; 2029 - 292 MW;
• Wind: 2020 - 699 MW; 2029 - 908 MW;
• Solar PV: 2020 - 1042 MW; 2029 - 2930 MW.

(d) Electricity Imports - Exports

Traditionally, Bulgaria is a net electricity exporter. Electricity exports grew to 14.8 TWh in 2015, which was the highest level since 2001, but, they have gradually dropped to 9.0 TWh in 2019. It is worth noting that the NECP reports an almost constant projection for electricity export over the next years.

Electricity imports continued their upward trend until 2016, and have declined since - in 2019 they were around their 2012 level. The growth of electricity imports and exports is evidence of the opening of electricity market to neighbouring markets, including the establishment of an electricity exchange in 2016. Further integration of the regional markets and development of electricity exchanges can lead to increased cross-border trading.

(e) Tariffs

In Bulgaria, electricity prices for households are regulated. For low voltage business customers prices used to be regulated, but following a with a recent reform they are forced to choose a market supplier by the end of June 2021, otherwise they will be forced to purchase their electricity from the Supplier of Last Resort. The country has integral electricity tariffs[4] covering all electricity costs including power generation, transmission, distribution, supply, support to renewables, etc. After social unrest in the winter of 2013 the decisions of the Energy and Water Regulatory Commission led to the buildup of a considerable tariff deficit, which has since narrowed down over the past five years through the increase of different tariffs. Nevertheless, these decisions have alleviated only the current tariff deficit, while there is still the problem of financing past deficits, which were most severe in the period June 2013 - June 2015.

[4] Source: Electricity tariff deficit : Temporary or permanent problem in the EU (http://ec.europa.eu/economy_finance/publications/economic_paper/2014/pdf/ecp534_en.pdf)

Table 5.68 **Electricity price components for domestic consumers for the second half of the year (euro/ KWh) Band DC: 2 500 kWh < Consumption < 5 000 kWh**

(f) Cross-Border Interconnections

The existing international interconnectors in the Bulgarian power system provide the necessary technical prerequisites for significant electricity exchange volumes under both normal and unstable operating conditions, including emergency cases by tripping the 1,000 MW unit at Kozloduy NPP. Current interconnection capacity is around 7% of installed generation capacity and the National Energy and Climate Plan 2021-2030 has a goal of increasing it to 15%.

(g) Planned New Projects

There are several PCI's included within the guidelines for Trans-European energy infrastructure projects, to be developed as part of electricity interconnections with Greece and Romania upon whose completion there will be an increase of the cross-border capacity and will help to open up the North-South priority corridor.

Table 5.70 **Bulgaria's Electricity PCI Projects**

Name	Summary project information
Internal line between Dobrudja and Burgas	It belongs to Cluster Bulgaria Romania capacity increase. Construction of a new 400kV AC single-circuit line (OHL) of 140 km and with a capacity of 1700 MVA connecting Dobrudja and Burgas (onshore)
Internal line between Maritsa East 1 and Bourgas	It belongs to Cluster Bulgaria - Greece between Maritsa East1 and N. Santa. Construction of a new 400 kV AC line (OHL) of 150 km and with a capacity of 1700 MVA between Maritsa East 1 and Burgas (onshore)
Interconnection between Maritsa East 1 (BG) and N. Santa (EL)	It belongs to Cluster Bulgaria - Greece between Maritsa East 1 and N. Santa. Source: Electricity Transmission System Operator

Electricity Imports Outlook

Given the "non-regret" EU low-carbon policy an increase is expected of carbon free generation through the development of RES and nuclear power. However, the capabilities of the electricity system are not evenly distributed throughout the year and during prolonged cold spells in the winter the system might need to resort to using its tertiary reserves or imports of electricity.

Renewables

(a) Overview of Sector's Development

According to the RES Directive 2009/28/EC and the National Renewable Energy Action Plan, Bulgaria is required to achieve a national target of 16% share of renewable energy in gross final consumption of energy by 2020. Bulgaria is among the three countries which have already reported fulfilment of the target. According to the latest Eurostat data, Bulgaria's renewable energy target for 2020 has already been fulfilled since 2013, and in 2018 their share was 20.5%.

The factors which contributed to the significant rise of RES in the gross final consumption of energy in in the past years, are the following:

- Increased consumption of renewable energy (biomass) for heating
- The renewable energy consumption for heating and cooling purposes in 2018 exceeded the 2020 goal for this sector (heating and cooling) by over 50% (or 12.7 percentage points). This is the result of the direct use of biomass (forest wood) for heating purposes in households.
- Significant growth in RES for electricity generation.
- The RES share in electricity in 2018 was about 2 percentage points below the 2020 target (for the electricity sector).
- Decreasing gross final consumption of energy.

Table 5.71 **Grosstime energy consumption in 2018**

	Share of RES in Gross Final Energy Consumption in 2018	National target 2020
Electricity	22.1%	23.8%
Heating&cooling	33.3%	20.6%
Transport	8.1%	10.0%
Total	20.5%	16.0%

Source: Eurostat

(b) Latest Legislation, Incentives and National RES Policy

The promotion of renewable energy in Bulgaria is foreseen by Energy Act (EA) and the Law on energy from renewable sources (LERS). National support measures for RES producers include mandatory priority connection to the grid, priority dispatching and the obligatory purchase of their net specific electricity production, which is determined by the regulator based on technology and date of connection to the grid, at preferential prices, also set by the EWRC (Feed-in Tariffs). All RES producers which sell electricity at preferential prices must apply and obtain certificates of origin for the generated energy. These certificates are issued by SEDA.

Since the beginning of 2018 all producers with installed capacity of no less than 5 MW were obliged to sell their electricity, not intended for the regulated market, on the Independent Bulgarian Energy Exchange (IBEX). As of July 2018 the 5 MW threshold was lowered to 4 MW and RES producers no longer have a production quota for the regulated market. They now sell all their electricity on the IBEX, and for quantities up to their yearly net specific production they receive a Feed-in Premium, rather than the Feed-in Tariff, which they received until June 2018. In this way the support mechanism for RES changed from a Feed-in Tariff (or a preferential price) paid to each producer for their yearly net specific production, all of which was sold on the regulated market, to Feed-in Premium, which is the difference between the Feed-in Tariff and a projected average market price, determined by the Energy and Water Regulatory Commission. Hence, as of June 2019 the scope of producers has broadened, to RES producers with installed capacity of no less than 1 MW.

Overall, the promotion of renewable energy for heating and cooling is not well developed. Project development of local heating distribution networks and small decentralized heating and/or cooling shall benefit from incentive measures but they are not yet foreseen in the legislation.

(c) Installed Capacity per Source (in MW)

Installed electricity capacities have stagnated in recent years as the 2020 RES target was achieved much earlier and the preferential treatment of investors was significantly reduced.

Table 5.72 **Installed RES capacity per source, MW, 2015-2019**

	2015	2016	2017	2018	2019
Hydro	**3,198**	**3,204**	**3,204**	**3,208**	**3,211**
Renewables	**1,806**	**1,813**	**1,821**	**1,826**	**1,833**
Solar PV	1,041	1,043	1,046	1,052	1,059
Wind	701	701	701	700	700
Biomass	64	69	74	74	74
Total	**5,004**	**5,017**	**5,025**	**5,034**	**5,044**

Source: ENTSO-E Transparency Platform

(d) Planned New Major Projects - RES Market Outlook

There are no new major projects planned. However, the Electricity Transmission System Operator anticipates some 1,888 MW of new Solar PV, 200 MW of extra Wind Power and 210 MW of additional Biomass in generating capacity to be integrated into the grid during the period 2020-2029.

Energy Efficiency and Cogeneration

(a) National Targets

Energy Efficiency: The National Energy and Climate Plan 2021-2030 sets measures and policies which should lead to a 32.5% improvement in energy efficiency, resulting in savings of more than 8,325 GWh of energy by 2030. Expressed in absolute terms, Bulgaria aims to reduce the energy intensity of its GDP by 2,6% annually during the period 2020-2040. The country has tried to reach its 2020 EE target through an Obligation Scheme and Obligated Parties, as well as Alternative

Measures. However, there is no adequate financial compensation mechanism in place and the Obligated Parties are reluctant to make large investments, as they cannot achieve a break even on their investments. As a result, in recent years, the government has tried to increase the share of Alternative Measures in reaching its 2020 target.

Cogeneration: The National Plan projects a significant increase in biomass for heat production due to the development of cogeneration plants (from 4 GWh in 2020 to 2497 GWh in 2030).

(b) Incentive-based Initiatives in the Building Sector (planned or already in place)

The Bulgarian Law on Local Energy Levies and Taxes envisages some incentive-based measures in the building sector, addressed to owners of buildings with energy performance certificates from class A to class D. These owners can be exempted from building tax payment obligations for a limited period of 3 to 10 years depending on the type of certificates, the year of issuance of building exploitation permission and RES integration.

(c) EU Funded (or otherwise funded) Energy Efficiency Programmes in the Building Sector and Planned New Major Projects

A National Programme for Energy Efficiency of Multi-Family Residential Buildings was approved in February 2015 with an initial budget of 1 bln. Euro and latter increased to 2 bln. Euro, aimed at financing energy efficiency measures, mainly upgrading. The programme was in place between 2015 and 2017. Currently, there are talks of restarting it with somewhat different parameters - both regarding financing and technical requirements, however, a decision is yet to be made.

Being one of the main problems of Bulgaria, energy efficiency is the focus of EU's Operational Programme "Regions in Growth"2014-2020 (OPRG). The special investment priority for energy efficiency and RES projects concerns public buildings, housing sector and student dormitories.

The Kozloduy International Decommissioning Support Fund (KIDSF) has been established, and administered by the European Bank for Reconstruction and Development (EBRD), in order to support the decommissioning activities and mitigate the negative consequences of nuclear units's 1-4 early closure. Part of the purpose of the KIDSF is to improve energy efficiency.

(d) Cogeneration: Regulatory Framework, Installed Capacity

The promotion of electricity production from high-efficient cogeneration in Bulgaria is required by the Energy Act (EA), transposing the relevant EU legislation. National support measures include priority connection of cogeneration capacities to the electricity grid and the obligatory purchase of the net electricity produced at preferential prices, set by the EWRC. All producers of electricity from highly-efficient cogeneration must obtain certificates of origin, for the generated quantities, issued by EWRC. As of January 2019, all such producers have to sell the electricity produced on the electricity exchange while the preferential prices were substituted with Feed-in Premiums.

The main CHP producers are district heating companies and industrial auto producers and both their electricity and heat capacity has been increased over the past five years.

Table 5.73 **Installed CHP capacities, MW, 2014-2018**

	2014	2015	2016	2017	2018
Gross Electricity Capacity	961	1121	1285	1046	1038
Net Heat Capacity	3400	3728	4122	3996	3977

Source: National Statistical Institute

Energy Legislation & Regulatory Framework

There is extensive legislation covering the fields of electricity generation, hydrocarbons and Renewable Energy Sources. This legislation is summarized as follows:

Electricity

The Energy Act provides for licensing regimes in the electricity sector.

Electricity prices in the balancing market as well as the price for the electricity supplied by the Supplier of Last Resort, are not determined by the Regulator (thus not subject to regulation in the strict sense), but are determined by the licensee for the respective activity under rules and methodology approved by the Regulator.
The requirements for the persons applying for a license are set forth in the Energy Act and the Ordinance for licensing of the activities in the energy field, State Gazette No. 33 of 5 April 2013 ("Licensing Regulation").

The Commission, in accordance with its powers, has approved the Rules for Trade with electricity (State Gazette No. 66 of 26 July 2013, as amended and supplemented).

The transmission and grid access are regulated by the Energy Act and a special Ordinance No. 6 of 12 December 2014, for the connection of producers and consumers of electricity to the electricity distribution and transmission networks (the "Connection Ordinance").

Hydrocarbons

The natural gas sector is regulated by the Energy Act and a number of Ordinances and Rules issued by the Council of Ministers and the Energy and Water Regulatory Commission. This legislation conforms to the fundamental EU guidelines in the sector.[5]

Renewables - Energy Efficiency

The Renewables Act basically preserves the principles of the previous system of encouragement and provides for some additional mechanisms for the encouragement of investments in renewable energy generation. It also preserves the system of encouragement for generation of electricity from renewables based on Feed-in Tariffs, later changed into Feed-in Premiums.[6]

5

CROATIA

Croatia

Economic and Political Background

Croatia's GDP fell at a milder, albeit still notable, pace of 7.0% year-on-year in the fourth quarter of 2020, improving from the 10.0% contraction seen in the third quarter. Q4's result marked the third successive quarter of contracting output, as lingering restrictions throughout most of the period weighed on activity. All in all, GDP tumbled 8.4% in 2020, contrasting 2019's 2.9% expansion and logging the worst reading in over two decades.

Q4's milder contraction reflected a broad-based improvement in private consumption, public spending, fixed investment and exports. Household spending fell 4.5% year-on-year in the final quarter, softening from Q3's 7.5% drop. In addition, fixed investment rebounded solidly in Q4, growing 4.2% and swinging from the 3.0% contraction tallied in the prior quarter. Meanwhile, government consumption edged up in the quarter, increasing 1.6% (Q3: +1.5% y-o-y).

On the external front, exports of goods and services fell 9.8% on an annual basis in the fourth quarter, softening markedly from the third quarter's 32.3% dive, amid firming foreign demand. In addition, imports of goods and services slid at a slower rate of 7.6% in Q4 (Q3: -14.1% y-o-y).

IMF estimates that Croatia's GDP will expand by 6.0% in 2021, significantly higher than -9.0% in 2020.

A judicial crisis emerged in March 2021 when President Zoran Milanović decided to support Zlata Đurđević as a candidate for the position of the Supreme Court's president. However, Đurđević was not among those who applied through the official procedure and, therefore, was not considered a candidate. This sprawled a long-lasting feud between the President and the government, while at the same time a new corruption issue in the Croatian judiciary occurred.

Energy Policy

National Energy Policy

The basic act defining energy policy and planned energy sector development is the Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050, which was approved by the Croatian Parliament on February 28, 2020. The Energy Development Strategy is a step towards the realization of a low carbon vision and provides a transition to a new era of energy policy, ensuring an affordable, secure and high-quality energy supply, without any burden on the state budget or the need for state aid and incentives. The envisaged energy transition process will be capital intensive, with no incentive measures in terms of state aid, but with the expected greater involvement of the private sector/ capital in financing RES projects.

Croatia's energy policy and strategy is focused on achieving EU's goals in terms of reducing greenhouse gas emissions, increasing the share of RES, energy efficiency, security and quality of supply, and developing the EU's internal energy market, as well as making available the necessary resources, energy infrastructure and thus ensuring competitiveness of the economy and the energy sector.

The transformation of the energy sector into a low greenhouse gas system will involve all sectors of energy production and consumption, as well as systems that transmit and supply energy to customers. In their transformation, energy systems must continue to fulfil their primary purpose, which is secure supply of energy to all customers, at reasonable prices and with minimal environmental impact.

The main determinants of the pursued changes in the energy sector are the following:

- The strengthening of the energy market as a supporting component for the development of the energy sector. Emission unit prices is seen as a key economic mechanism for controlling the speed of transition.
- The full integration of Croatian energy market into the international energy market technology, research, services, production, and in particular EU's internal energy market.
- The strengthening of security of energy supply through the increase of domestic production and the integration of energy infrastructure, as well as the introduction of Capacity Remuneration Mechanisms (CRM).
- The increase of energy efficiency in all parts of the energy chain (production, transport/ transmission, distribution and consumption of all forms of energy).
- The continuous increase of the share of electricity in energy consumption with the aim of reducing fossil fuel consumption.
- The continuous increase of electricity production with reduced greenhouse gas emissions - primarily from RES.
- The development of the energy sector should be based on commercially available technologies, in particular hydroelectricity, sun and wind and other RES.
- The focus on financial support for the development of bioeconomy and sustainable waste management and research, on pilot and demonstration projects.
- The provision of risk mitigation funds for demanding technologies and new commercial technologies.

The Integrated National Energy and Climate Plan for the period 2021-2030 builds on existing national strategies and plans and takes into consideration the five dimensions of the Energy Union: decarbonisation, energy efficiency, energy security, the internal energy market and research, innovation and competitiveness. There are four key strategies, which address the five dimensions of the Energy Union. The first and second are covered in the **"Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050"** which defines the optimal energy mix and development projects with the aim of ensuring the energy independence of the Republic of Croatia, with particular emphasis placed on strengthening the production of energy from renewable sources. Also, special attention is paid to the security of supply, sustainability and competitiveness of the energy system.

The strategic document which deals with decarbonisation is the **Draft of the Low-Carbon Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050.** One of the objectives within the decarbonisation dimension is the adaptation to climate change, which is elaborated in the Draft of the Climate Change Adaptation Strategy in the Republic of Croatia until 2040 with an outlook to 2070 with the action plan.

The key document for the energy efficiency dimension is the **Long-Term Strategy to Encourage Investment in the Renovation of the National Building Stock of the Republic of Croatia by 2050**, which promotes the need to invest in the building stock. The revised strategy aligns the renovation objectives with the NECP in light of demographic trends and activities in the construction sector, with trends of accelerated abandonment of the existing building stock of poorer properties and gradual growth in new construction. The current energy renovation rate of 0.7% per year will gradually rise to 3% over the 2021-2030 period, with a 10-year average rate of 1.6%. An important element is the introduction of additional measurable indicators for the energy renovation of buildings, which will strengthen the process of conversion of the stock into nearly zero-energy buildings, i.e. climate neutral.

The dimensions of energy security and the internal energy market have been elaborated within the framework of the **Energy Development Strategy.**

The national strategies relevant to the dimension of research, innovation and competitiveness are the **Strategy of Education, Science and Technology, the Smart Specialization Strategy of the Republic of Croatia 2016 - 2020 and the Innovation Promotion Strategy of the Republic of Croatia 2014 - 2020.** With regard to these strategies, this document also outlines systematic measures expected to contribute to research, innovation and competitiveness of the Croatian economy in sectors relevant to the energy transition.

The key objectives outlined in the Integrated Energy and Climate Plan are the **reduction in greenhouse gas emissions in the Republic of Croatia for the year 2030, the share of RES in the gross final energy consumption and energy efficiency, expressed as consumption of primary energy and direct consumption of energy.**

Table 5.74 **Achieved emission reductions in 2017 and targets for 2030**

Scope	GHG emissions in 2005 (kt CO2e)	Achieved emissions reduction in 2017 compared to 2005	Target for the period 2013-2020 compared to 2005	Target for the period 2013-2020 compared to 2005
ETS sector	10,649	-21.4%	-21.4% (EU-wide target)	-21.4% (EU-wide target)
Non-ETS sectors	17,404	-4.2%	-10% (EU-wide target) +11% (target for Croatia)	-30% (EU-wide target) -7% (target for Croatia)

Governmental institutions

Key institutions and their role in policy making include the following:

Ministry of Environment and Energy - This is the umbrella institution for the implementation of national energy and climate policies in Croatia.

Croatian Energy Regulatory Agency (HERA) - this is an autonomous, independent and non-profit public institution, which regulates energy activities in the Republic of Croatia. HERA's obligations, authorities and responsibilities are based on the Act on the Regulation of Energy Activities, the Energy Act and other acts regulating specific energy activities. Its role is to regulate energy activities and is responsible for the improvement and implementation of by-laws, issuing licenses, setting tariffs, certifying the eligible producer status, etc.

Croatian Energy Market Operator (HROTE) - It performs the public service of organizing the electricity and gas market and analyses and proposes measures for its improvement. It also undertakes tasks related to the various incentives required for electricity production from renewable energy sources and cogeneration, which involves collecting compensation from suppliers and calculating and allocating funds on the basis of concluded contracts with eligible producers entitled to an incentive price or support scheme.

The Croatian Hydrocarbon Agency provides operational support to competent bodies involved in hydrocarbon exploration and exploitation, geothermal energy, underground storage of natural gas, as well as the permanent disposal of gases in geological structures and activities for ensuring compulsory stocks of oil and petroleum products.

Ministry of Construction and Physical Planning - It is responsible for creating policies and measures to achieve the set energy savings targets in buildings. Prepares laws and regulations, strategies and programmes in connection to long-term integral renovation of buildings: family houses, apartment buildings, commercial non-residential buildings and public sector buildings.

Environmental Protection and Energy Efficiency Fund (EPEEF)- This is responsible for co-financing the measures defined in the national energy and climate plans, and acts as an intermediate body level 2 for the use of ESI funds under the Operational Programme Competitiveness and Cohesion 2014 - 2020, in parts relevant to energy and climate. The EPEEF also allocates the funds collected from emissions through auctions in the EU market, according to the Plan for the use of funds acquired from the sale of emission allowances through auctions in the Republic of Croatia for the period from 2017 to 2020 (OG No. 19/18).

The EPEEF also manages the funds paid by energy suppliers in the event of failure to fulfil their obligations under Article 13 of the Energy Efficiency Act and is obliged to invest them in alternative measures.

Energy Demand and Supply

The total primary energy supply (TPES) in Croatia in 2018 totalled 9,769 ktoe. In the period from 2013 till 2018, the total primary energy supply decreased at an average annual rate of 0.3%. In this period, there was a decrease in the consumption of coal and coke and hydropower, whereas the share of consumption of other energy forms increased. In 2018, the total primary energy supply in Croatia decreased by 1.2% as compared to the previous year.

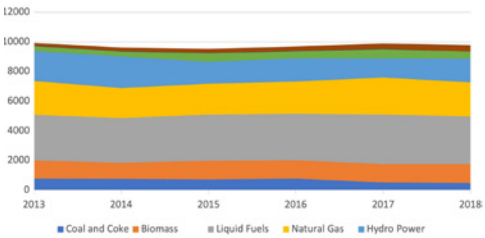
Hydropower increased by 24.5% due to favourable hydrological conditions. As a result of these conditions consumption of imported electricity dropped by 22.5% and natural gas decreased by 7.9%. Liquid fuels had the highest share in the total consumption of the country in 2018 at 32.9%, followed by natural gas at 23.6%, hydro at 20.5%, fuel wood at 12,5%, coal and coke at 7.8%, and other energy sources having smaller shares. Croatia's energy mix between 2013 and 2018 is shown in Table 5.76.

Table 5.76 **Total primary energy supply (ktoe)**

	2013	2014	2015	2016	2017	2018
Coal and Coke	769	755	713	768	517	486
Biomass	1,234	1,102	1,258	1,253	1,244	1,271
Liquid Fuels	3,066	3,005	3,127	3,124	3,340	3,213
Natural Gas	2,282	2,021	2,082	2,175	2,500	2,303
Hydro Power	2,028	2,125	1,472	1,568	1,285	1,600
Electricity	333	340	584	476	598	463
Heat	15	12	15	16	16	15
Renewables	186	251	270	308	385	414
TOTAL	9,913	9,611	9,521	9,688	9,885	9,765

Source:EIHP

Figure 5.54 **Total primary energy supply (ktoe)**



Source EIHP

In 2018, Croatia's primary energy production reached 5,284 ktoe. In the same year, hydro power had the largest share of 30.3% in the total primary production followed by fuel wood with a 28.5% share, natural gas with 19.5%, crude oil with 14.1% and renewables with 7.3% (solar and wind).

During 2013-2018, primary energy production decreased at an average annual rate of 1.9 percent. Noteworthy decreasing trends are recorded in the production of natural gas (7.4% long-term annual decrease) and hydropower (4.6% long-term annual decrease). Production of other primary forms of energy increased.

In 2018, Croatia imported 7,590 ktoe and exported 3,005 ktoe of primary energy sources. The largest share of 67.1% corresponded to crude oil imports and petroleum products, which were followed by natural gas at 17.3% and electricity at 17.3%. The share of coal and coke in total primary energy import was 6.2%.

At the same time, Croatia exported 3,005 ktoe of primary energy. The largest share, which amounted to 81.48%, was attributed to petroleum products, while biomass contributed with a share of 9.2% and electricity with a 5.8% share.

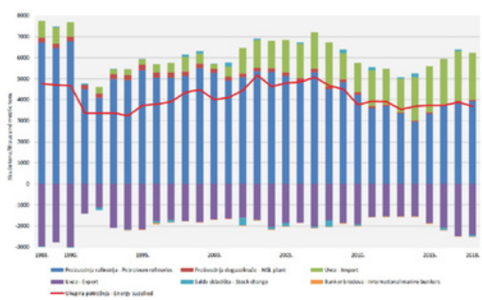
The country's energy dependency for 2018 amounted to 45.9%, which represents a decrease of 1.2% compared to the previous year.

The Energy Market

Oil and Petroleum Products

The total consumption of liquid fuels in 2018 amounted 3,213 ktoe, which was the highest share of all primary products in Croatia (32.9%). In terms of final energy consumption, the share of liquid fuels was even larger and amounted to 40.7% in 2018. Croatia produced 732.1 thousand tons of liquid fuels, which was about 20% of the country's liquid fuels needs. Total reserves of oil and condensate amounted from 6,998.1 thousand m^3 for P1 to 10,009.8 thousand m^3 for 3P.

Figure 5.55 **Petroleum products supply in the Republic of Croatia**



Source EIHP

Upstream Activities

Crude oil is produced from 38 oil fields and gas condensate products from 9 gas fields. Exploration and production of oil has a long history in Croatia that dates back to the 1850s, when the first well was drilled near seeps. Geophysical surveying techniques were also applied at an early date. Peklenica was the first well drilled in 1884 where oil was exploited through shallow mineshafts until the first well was drilled. In the period after the end of the Second World War till 1950, oil and gas exploitation at shallow depths continued.

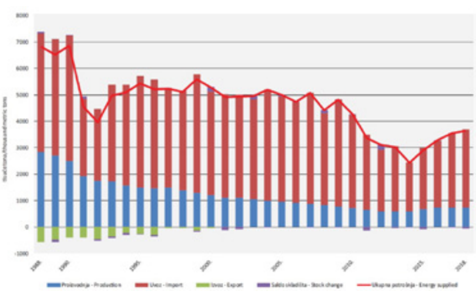
During the 1960s, some 20 discoveries were made out of at least 170 New Wildcat Field (NFWs) drilled. During the 1970s, about 180 NFWs were drilled. They resulted in 19 oil and oil/gas discoveries, and 13 gas fields.

During the 1980s, at least 124 exploratory wells were drilled. Of that number, 22 wells were commercially successful, pointing out the increased maturity of the area from an exploration perspective. During the 1990s, at least 62 new exploratory wells were drilled, and 10 of those wells were ascribed as commercially viable. Seven wells were drilled from 2000 to 2008, which resulted in three gas and gas/ condensate discoveries.

In the period from 1952 until now Croatia discovered and put into commercial operation 45 oil and 30 gas fields. From these fields, 106 million tons of oil, about 9 million tons of condensate and 74 billion m^3 of natural gas have been produced until today. The maximum annual amount of oil produced in Croatia was recorded in 1981, and amounted to 3,140,777 tons. At the same time, the largest quantity of natural gas production was 2,176,657,000 m^3, which was achieved in 1989. The largest oil fields in Croatia are the following: Beničanci, Stružec, Jaundice, Šandrovac, Ivanic, Lipovljani, Jamarice, Đeletovci, Jagnjedovac and Bilogora, while large gas fields include: Molve, Boksic, Kalinovac, StariGradac and Okoli.

In total, more than 550 oil and gas wells have been developed onshore and offshore in Croatia over the last 70 years.

Figure 5.56 **Crude oil supply in the Republic of Croatia**



Source EIHP

Today the **Croatian Hydrocarbon Agency** is monitoring exploration and exploitation of hydrocarbons in the Republic of Croatia. Furthermore, the Agency is responsible for defining exploration activities, for establishing rules and reputations for exploration and exploitation of hydrocarbons and for providing operational support to competent bodies during licensing rounds. In addition, the Agency supervises all hydrocarbon exploration of production activities and is in charge for all licensing rounds.

Over the last years, Croatia has created the necessary legal framework and attracted large investments in exploration and production. At Croatia's 1st Onshore License Round in July 2014, six onshore exploration blocks were offered, covering the areas of Drava, Sava and Eastern Slavonia. Upon closing the License Round, the government of Croatia awarded licences to INA-INDUSTRIJA NAFTE Ltd., a Croatian company, and Canadian company Vermilion. Three years after the signing of the contract, the first onshore licensing round yielded the first results with two companies reporting gas finds.

In 2018, Croatia launched the country's 2nd onshore licensing round offering seven onshore blocks all located in Croatia's prolific Pannonian Basin. This is the second of three planned onshore licensing rounds. The seven exploration blocks offered in this licensing round are located in Croatia's highly prolific Pannonian Basin. The total acreage available is 14,272 km^2. The available blocks range in area from 1,361 to 2,634 km^2.

Croatia's Pannonian Basin is well-known and has a long history of oil and gas producing fields. A large acreage in the basin, remains underexploited with respect to deposits. Preliminary analysis of the seismic and other available data confirm that the available acreage contains significant remaining potential. The licensing round concluded in mid-2019 when the government of Croatia awarded new licenses for the exploration and production of hydrocarbons in six onshore exploration blocks.

Oil Refining and Oil Marketing

Development and production of oil and gas in Croatia has been carried out by **INA-Industrija nafte, d.d.** (INA, d.d.). INA Group had a leading role in Croatian oil business and enjoyed a strong position in the region in oil and gas exploration and production, oil processing, and oil products distribution activities. INA, d.d. is a listed company with the Hungarian MOL Group and the Croatian Government as its biggest shareholders, while a minority of its shares is owned by private and institutional investors. INA Group is comprised of several affiliated companies wholly or partially owned by INA, d.d.. The Group owns and operates three oil rafineries: Oil Refinery Rijeka (Urinj), Oil Refinery Sisak and Lube Refinery Zagreb Ltd.

Rijeka oil refinery (Urinj) is located in the northern part of the Adriatic Sea. It is the shortest and most convenient connection to central Europe and with the Mediterranean. In Rijeka, INA has built a road, railway, marine and pipeline infrastructure for the supply and shipment of products, crude oil and petroleum derivates.

Rijeka oil refinery is connected through an underwater pipeline - 7.2 km long and 20" in diameter - with the port and petroleum terminal in Omišalj, on the island of Krk (owned by JANAF). The capacity of the oil refinery at Rijeka is 4.4 million tons/annum. In 2011, INA started a comprehensive modernization and upgrading plan of the refinery. Thanks to the planned investment in the heavy residue processing project, the modernisation of existing units, a new port with a closed coke storage facility and greater overall complexity, the Rijeka Oil Refinery will become a top European refinery. Investment in the heavy residue processing project amounts to over HRK 4 billion (€530 million), which is the largest single investment project in the history of the INA company.

The Sisak oil refinery is an inland refinery located some 50 kilometres to the south of Zagreb. The capacity of the Sisak Oil Refinery is 2.2 million tons/annum. The refinery development program foresees the concentration of crude oil processing activities in the Republic of Croatia at the Rijeka Oil Refinery and, as part of this, the conversion of the Sisak Oil Refinery into an industrial centre is foreseen. As part of the renovation work attention is given to the development of bio-component processing projects. These are expected to operate profitably and contribute to the positive development of the regulatory environment in the EU and the Republic of Croatia. As part of INA's renovation project a modern logistics centre has been included together with bitumen production, lubricant production and other sustainable and economically viable activities. In 2018, there were about 867 petrol stations in total in Croatia, out of which 388 petrol stations were owned by INA.

Imported crude oil is transported to regional oil refineries by the JANAF oil pipeline system owned and operated by **JADRANSKI NAFTOVOD, Joint Stock Co. (JANAF Plc.)**, headquartered in Zagreb. The JANAF pipeline was constructed in 1979 as an international oil transportation system from the tanker and terminal port of Omišalj to domestic and foreign refineries in Eastern and Mid-Europe. The designed pipeline capacity amounts to 34 million tons of oil a year, and the installed one is 20 million tons. The storage capacity at the Omišalj, Sisak and Virje terminals amounts to 1,940,000 m3 for oil and 222,000 m^3 for oil products in Omišalj and Zagreb.

The JANAF oil pipeline system, consists of a reception and forwarding terminal at Omišalj on the island of Krk. A pipeline system of total length of 631.3 kilometres has been developed, which includes the following branches: Omišalj-Sisak; Sisak-Virje (with a section to Lendava)-Gola (Croatian-Hungarian border); Sisak-Slavonski Brod (with asection to Bosanski Brod)-Sotin (Croatian-Serbianborder),receptionand forwarding terminals in Sisak, Virje and near Slavonski Brod, Omišalj-Urinj submarine pipeline, which connects terminal port of Omišalj on the island of Krk with the INA-Rijeka Oil Refinery on land, the island of Krk-mainland section in the total length of 5.05 km, with the submarine section of 730 meters, as a part of Omišalj-Sisak section.

Map 5.12 **JANAF pipeline system**

Source: JANAF

The inspection, evaluation, rehabilitation, upgrading and reconstruction of the JANAF oil pipeline project was financed by WBIF and had the objective of preparing a tender dossier in order to replace a section of the oil transportation network between Omisalj to Sisak with an underground/undersea pipeline, and also to conduct a review of the entire Croatian oil network, with a view of identifying potential future investment requirements to rehabilitate and reconstruct the network in Croatia. Reconstruction, upgrading, maintenance and capacity increase of the existing JANAF and Adria pipelines linking the Croatian Omisalj seaport to the Southern Druzhba (Croatia, Hungary, Slovak Republic) aim at increasing capacity, operation and security of oil pipelines from Omisalj (HR) through Hungary to the Southern Druzhba pipeline in Slovakia.

The **Croatian Hydrocarbon Agency** is responsible for maintaining the compulsory stocks of oil and petroleum products of the Republic of Croatia at the level corresponding to 90 days consumption by July 31st, 2012. Croatian Hydrocarbon Agency performs activities and carries out tasks within the scope of activities and competences prescribed by the Act, including all activities necessary for performing tasks stipulated by laws and other decisions, particularly the following:

- Collection of the fee for the compulsory stocks of crude oil and petroleum products.
- Purchase and sale of crude oil and petroleum products for the purpose of forming and replenishing stocks.
- Organization, supervision and management of compulsory stocks of crude oil and petroleum products.
- Spending of funds for designated purposes in order to form and store compulsory stocks of crude oil and petroleum products.
- Determining the conditions for storing compulsory stocks of oil and petroleum products.

Natural Gas

Croatia's total consumption of natural gas in 2018 amounted to 2.8 bcm, which is the second largest share at 23.6% of primary energy production. Total consumption of natural gas increased from 2013 by 0.2% yearly, with a decrease between 2018/2017 amounting to 7.9%. In terms of final energy consumption, the share of natural gas fuels was much smaller and amounted to 13.0% in 2013 (1 bcm).

In 2018, Croatia produced 1.2 bcm of natural gas, which correspond to about 45% of its natural gas needs. Proven reserves of natural gas amount to 10.3 bcm. Natural gas is produced from 18 on-shore and 3 offshore exploration areas, having a share of 45% of total domestic demand.

In 2018, 1.6 bcm of natural gas was imported from various countries. All imported natural gas was acquired in the open gas market. Croatia does not have any government supported long-term import contracts.

Figure 5.57 **Natural gas supply in the Republic of Croatia**

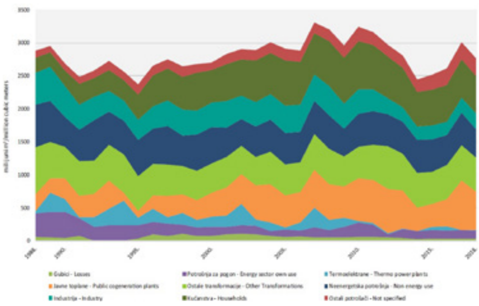
Figure 5.58 **Natural gas consumption in the Republic of Croatia**



Source EIHP

Transportation of natural gas is a regulated energy activity performed as a public service. The energy entity Plinacro d.o.o. is the transport system operator of the Republic of Croatia and is owned by the Republic of Croatia. Plinacro d.o.o. manages the network of the main gas and regional gas pipelines through which natural gas from domestic production (in the northern part of continental Croatia and the Northern Adriatic) and from imports via Slovenia (Rogatec-Zabok) and Hungary (Donji Miholjac-Dravaszerdahely) is transmitted, to exit measuring-reduction stations where gas is delivered to gas distribution systems and to end (industrial) customers directly connected to the transport system.

The total length of the gas transport system in the Republic of Croatia at the end of 2019 was 2,531 km, of which 952 km were main gas pipelines under a working pressure of 75 bars, and 1,579 km of branch gas pipelines under a working pressure of 50 bars.

The gas is received into the transport system from nine connection points at entry measuring stations. Six of which serve for receiving gas from production fields on Croatian territory, two connection points are international connection points and serve for receiving gas from import routes, while one is for withdrawing gas from the Okoli underground gas storage facility (UGS Okoli). Gas is delivered to transmission system users through 157 exit measuring-reduction stations.

The **underground gas storage** at Okoli is managed by the Podzemno skladište plina, Ltd. company, which is owned by PLINACRO. The designed capacity of the underground gas storage is 5 050 GWh. Maximum injection capacity is 200 MWh/h and the maximum withdrawal capacity is 300 MWh/h.

Gas distribution is a regulated energy activity performed as a public service. In 2018, gas distribution in the Republic of Croatia was performed by 35 energy entities.

According to the Croatian Gas Association total distributed gas quantities in the Republic of Croatia in 2018 amounted to 1.2 bcm. 0.6 bcm were distributed to households and 0.6bcm to users of the commercial sector. In 2018, the total number of distribution system users amounted to 671,740. In 2018 there were 626,307 households' customers, and 45,433 commercial users. The total length of all gas distribution systems in the Republic of Croatia at the end of 2018 amounted to 18,067 km.

In 2018, 49 gas suppliers grouped into 14 balancing groups, used the gas transmission service. Head of the balance groups is HEP Trade d.o.o. which absorbed 31.2% of the gas from the transportation system. Other balance groups included HEP Trgovina d.d. with 27.4% gas volume, the INA balance group d.d. with 15.4%, the balance group Prvo plinarsko društvo d.o.o. with 12.2% of gas, while the remaining 10 balance groups were responsible for 13.8% of gas.

Major **planned new projects** are related to gas exploration (described in the oil section), development of an LNG terminal, the expansion of the gas transmission network and development of a new underground gas storage facility.

LNG Croatia LLC is a company established for the purpose of building and operating the infrastructure necessary for receiving, storing and regasifying liquid natural gas. In accordance with planned deadlines for the construction of the floating LNG terminal on the Island of Krk, a Final Investment Decision was taken on 31 January 2019.

The procurement procedure of the floating, storage, and regasification unit (FSRU vessel) was carried out in November 2018. The bid from company Golar was evaluated as the most economically viable, which offered a conversion of an existing LNG tanker to the FSRU vessel worth €159.6 million. It is an LNG carrier, which was built in 2005 and sails under the name "Golar Viking.

All activities related to the commissioning of the terminal begun on 2 of December 2020: the testing of certain systems of the FSRU vessel and the testing of the onshore facilities. Commercial operations at the terminal started on 1 January 2021, after the successful commissioning of the FSRU and overall LNG terminal infrastructure activities in December 2020.

In accordance with the conducted procurement procedures the total capital expenditure of the project was reduced to €233.6 million (the initial planned investment amounted to €383 million). In addition to an already approved grant from the European Commission in the amount of €101.4 million, the government of the Republic of Croatia has made a decision on financing the first phase of the project for the floating LNG terminal on the Island of Krk with which a grant of the order of €100 million was provided. The remaining part of the required capital expenditure in the amount of €32.2 million will be provided by the shareholders of LNG Croatia LLC through an increase of equity.

At 15th June 2020, LNG Croatia LLC finished the long-term binding process for booking the capacity of the LNG terminal. All free terminal capacity has been booked for the next 3 years and that there is no more available capacity. Plinacro Gas Transmission System Operator completed the development of the main Croatian gas system.

Future system development is related to regional interconnection pipelines (IAP, neighbouring countries connections) and transmission of gas from the Krk LNG terminal. Most of the pipelines, which are in the focus of future development plans, are nominated as EU PCI projects and Energy Community Projects of Mutual Interest - PMI.

5. Croatia - Serbia interconnection (Slobodnica - Sotin - Bačko Novo Selo)

PSP d.o.o. underground gas storage operator intends to develop peak storage facility at Grubisno Polje. Peak storage facility Grubisno Polje project development will consist of two phases:

- **Phase I** will be the extraction of gas from the gas reservoir/gas field Grubisno polje. Facilities and installations will be built for gas treatment (natural gas plant), supervision system and process management, connecting pipelines to the wells, connecting pipelines to the main pipeline Virovotica-Kutina, access roads, water system etc.

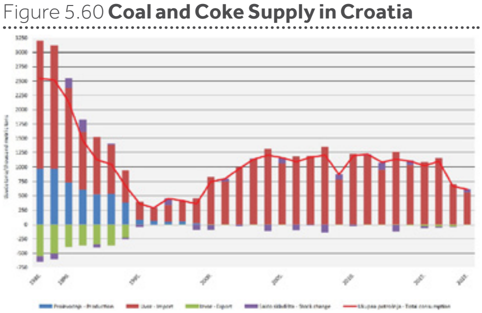
- **Phase II** concerns the development of the underground gas storage in the partially depleted gas reservoir of Grubisno polje. Working volume of new UGS will be a minimal 25 million m^3, with a maximum level of injection capacity up to 1.4 million m^3/per day and maximum level of withdrawal capacity from 1.7 to 2.4 million m^3/per day with a possibility of multiple injection and withdrawal circles during winter season. The primary task of this underground gas storage would be to ensure peak withdrawal capacities during winter season, or more precisely as a support during withdrawal of gas from the seasonal gas storage in UGS Okoli.

Solid Fuels

Total consumption of solid fuels (coal and coke) in 2018 amounted to 615.2 thousand metric tons, which is the fifth largest share of all primary products in Croatia (share of 5.0%). The total consumption of solid fuels has been decreased steadily from 2013 onwards by 11.6% yearly. In the period 2017-2018, consumption of solid fuels decreased further by 7.5%. Most of the coal is consumed in the energy transformation sector for power generation. In terms of final energy consumption, the share of solid fuels is much smaller and amounted to 3.0% in 2018. Some 95.0 thousand metric tons was used in the industrial sector, mainly by the cement industry.

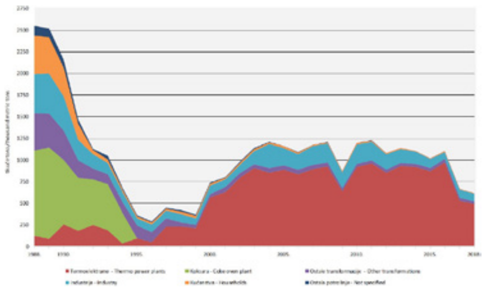
Proven coal reserves in Croatia amount to 45,149 thousand metric tons, but currently there is no coal production in Croatia. Total coal consumed in the Republic of Croatia is provided by imports. Brown coal and lignite are mostly imported from Bosnia and Herzegovina, the Czech Republic and Hungary. Coke is mainly imported from the neighbouring countries (Hungary, Italy, Poland and Czech Republic), while hard coal is procured at the international market and comes from the major coal exporting countries (In 2018 Russian Federation, USA and Columbia).

Figure 5.60 **Coal and Coke Supply in Croatia**



Source EIHP

Figure 5.61 **Coal and coke consumption in the Republic of Croatia**



Source EIHP

There are no plans for the revitalisation of old or the development of new coal or coke production facilities.

Electricity

Total consumption of electricity increased from 2013 by 1.5% yearly, with 2018/2017 increase amounting to 0.4%, reaching 17.2 TWh in 2018. In the final energy consumption in 2013 the share of electricity amounted to 20.3% (16.1 TWh). The installed electricity generating capacities in the Republic of Croatia include hydro and thermal power plants, owned by the HEP Group, an increasing number of wind power plants and other power plants using renewable energy sources and certain number of industrial power plants.

By the end of 2018 electricity generation capacities in Croatia encompassed 17 locations with hydro power plants, 7 locations with thermal power plants, one half of the installed capacities of the nuclear power plant Krško (located in the territory of Slovenia) and a large number of RES power plants. Thermal power plants are gas-fired, coal-fired and liquid fuel fired (only industrial plants). The total installed capacity of all power plants in the Republic of Croatia by the end of 2018 amounted to 5,000.4 MW. Out of this amount, 2,152 MW corresponded to thermal power plants, 2,199.5 MW to hydro power plants, 586.3 MW to wind farms and 67.7 MW to solar power plants. There is also 348 MW in the nuclear plant at Krško (50% of total available capacity) used by the Croatian power system. The total installed capacity of Krško NPP is 696 MW.

Table 5.77 **Electricity generation capacity in the Republic of Croatia (HEP Group ownership) in 2019**

Electricity generation capacity	Available power (MW)	Electricity produced in 2018
Hydro power plants (HPP)	2,199.5	7,784.9
Thermal power plants (TPP)	2,152.0	4,453.4
Wind power plants	586.3	1,335.4
Solar power plants	67.7	74.9
TOTAL	5,005.4	13,631.7

Source: EIHP

Industrial power plants include units within the industrial installations, which are connected to the electricity grid. Industrial power plants generate electricity/heat/mechanical energy for own use in industrial processes, while the electricity surplus can be sold to the transmission/distribution grid. These power plants are not a part of the HEP Group, but they have purchase agreements and can deliver the power they produce directly into the power system. Total installed capacity of industrial power plants amounted to about 150 MW in 2019.Most power plants that use renewable energy sources have the status of preferential electricity producers. In addition to securing the right of priority in the delivery of electricity to the electricity system, the status of preferential electricity producer was one of the conditions for obtaining incentives under tariff systems for the production of electricity from renewable energy sources and cogeneration.

Table 5.78 **Preferential electricity producers in 2018**

Plant type /primary energy source	Number of Plants	Installed Capacity (MW)	Electricity produced (GWh)
Solar	1229	52.43	69.2
Hydro	13	5.79	24.6
Wind	21	555.80	1,345.5
Biomass	28	58.33	291.9
Geothermal	0	0.00	0.00
Biogas	37	40.73	316.4
Landfill and wastewater treatment plants gas	1	2.50	0.1
Cogeneration	6	113.29	434.8
TOTAL	1,335	828.87	2,482.5

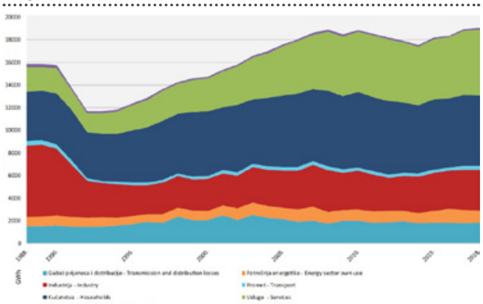
Source EIHP

Figure 5.63 **Electricity consumption in the Republic of Croatia (in GWh)**



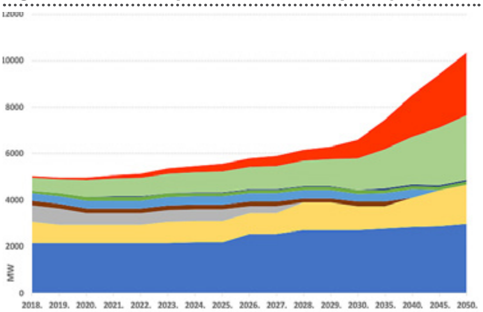
Source EIHP

According to the Energy Sector Strategy, it is envisaged that the total installed electricity capacity will increase from 5.05 GW in 2017 to 6.57 GW in 2030. On average, around 170 MW of new power plants per year are required to be built. The anticipated growth in the construction of RES power plants is significant. It is expected that from the initial 519 MW in 2017, the capacity of WPPs will increase to around 1,360 MW in 2030, and about 2,700 MW by 2050. On average, over the thirty-year period, 80 MW of new WPPs should be built annually, which is more than the historical average achieved of about 50 MW per year.

By 2030, about 770 MW of new photovoltaic projects are expected to be connected to the grid. About 470 MW relates to integrated photovoltaic projects, while about 300 MW should be built equally on the distribution and transmission network. By 2050, the total power of photovoltaic power plants would reach about 2,700 MW.

The end result and the structure of production capacities after 2040 is significantly influenced by the assumption that the Krško NPP license will be extended. If there is no license renewal, this production needs to be replaced by new sources (practically wind and solar). In other words, the conservative variant was assumed where it was necessary to invest in new low carbon projects. Sensitivity analyses show that a nuclear option would be competitive in the event that smaller generation units with lower construction costs become available in the market, compared to today's costs for large nuclear power plant projects in Europe. In this regard, it is necessary to monitor the development of new technologies in the forthcoming period, to analyse the competitiveness of the nuclear option and the development of announced projects in the region (eg. Slovenia, Hungary). In addition, the requirement for complete decarbonisation of all sectors could encourage greater use of nuclear energy given the potential for other applications (eg. cogeneration and hydrogen production).

Figure 5.64 **Power plant installed capacity by 2050**



Source: Energy sector strategy

According to the HOPS d.o.o. Croatian Transmission System Operator ten-year network development plan for 2020-2029, in the next three-year period a new power plant (EL-TO Zagreb, block L) is planned, with a capacity of 150 MW, for whose connection an appropriate connection contract has been concluded. Also, it has been agreed to increase the connection capacity of the existing HPP Varaždin after its planned renovation at 110 MW.

Table 5.79 **Planned power plants for connection to the transmission network with connection contracts signed**

Power plant name	Anticipated connection power [MW]	Estimated year of connection
EL-TO Zagreb blok L	150	2021
HE Varaždin	+16	2022
TOTAL	166	

Source: HOPS d.o.o.

New power plants which are in the process of licencing prior to the conclusion of the Connection Agreements are shown in Table 5.80.

Table 5.80 **Planned power plants to be connected to the transmission network**

HE Kosinj	33.7	medium term
TOTAL	1,553.7 MW/-990 MW	

Source: HOPS d.o.o.

In recent years, HOPS has received a large number of requests for the connection of new wind farms with a total capacity exceeding 2,000 MW. The size of WPP projects in the Republic of Croatia varies between 18 MW and 156 MW, and most are considered for connection to the 110 kV grid. In assessing the connection of planned hydroelectric power plants, two basic categories are distinguished:

- WPPs which have a Contract for connection to the transmission or distribution network - connection planned in the next three-year period,
- other WPPs (in different development stages but without connection contract) - connection planned for the next 10-year period.

It should be emphasized that the plans for connection of wind power plants presented here do not represent the final state of their construction and connection to the transmission network, since they depend on investor plans, on how the projects will be further developed.

Table 5.82 **Planned WPPs for the connection to the transmission network in 2020-2022 with connection contracts signed**

Power plant name	Anticipated connection power[MW]

Korlat	58
Opor	33
Boraja	45
TOTAL	725 MW

Source: HOPS d.o.o.

It should be mentioned that 15 additional WPPs projects are in different phases of project preparation with total anticipated capacity of 835.5 MW. By the end of the planned ten-year period, a total of 2,218.45 MW of wind power plants should be connected to the transmission network (provided that all of the mentioned WPP projects are completed). At the end of 2017, 2018 and throughout 2019, a considerable number of requests for connection of solar power plants to the transmission power network of the Republic of Croatia, with a total power exceeding 600 MW, were received by HOPS. The estimated power of individual power plants ranges from 17 MW to 150 MW.

SE Konačnik	35	2022
TOTAL	341 MW	

Source: HOPS d.o.o.

Five additional solar power plant projects are in different phases of project preparation with a total anticipated capacity of 410 MW.

Electricity transmission and distribution are regulated activities performed as public services. There is a single transmission system operator in the Republic of Croatia, Hrvatski operator prijenosnog sustava d.o.o. (Croatian Transmission System Operator Ltd) (hereinafter: HOPS), which is responsible for the security and reliability of the operation of the electric power system and the proper co-ordination for the operation of the production, transmission and distribution system. The transmission network and production facilities, for which operation HOPS is responsible for, are shown in Map 5.16.

Map 5.16 **The transmission network and production facilities of the Croatian electric power system (2018)**

Source: Croatian Transmission System Operator Ltd. (HOPS d.o.o.)

The total length of electricity transmission lines in 2018 amounted to 7,802 km (1,247 km - 400 kV lines, 1,246 km - 220 kV lines, 5,309 km - 110 kV and medium voltage). A total of 183 transformer stations were to be found in the transmission system.

The total length of distribution system lines in 2018 amounted 103,327 km (10 km - 110 kV lines, 4,488 km - 35(30) kV lines, 9,738 km - 20 kV lines, 27,505 km - 10 kV lines, 61,586 km -0,4 kV lines and additional 31,527.4 km are for household connections). There was a total of 27,416 transformer stations to be found in the distribution system.

The method used for determining the costs of the transmission system operator in the Tariff system for electricity transmission, without tariff item amounts (Official Gazette, Nos. 104/15 and 84/16) and the distribution system operator in the Tariff system for electricity distribution (Official Gazette, Nos. 104/15), adopted by HERA in September 2015, is the method of approved expenses. The methodology is based on the following principles and rules:

- total costs must be justified, and must be impartial and transparent,
- the tariff items for each tariff model throughout the Republic of Croatia are the same,
- the amounts of tariff items for each tariff model shall be determined in such a way as to correspond as closely as possible to the total costs incurred by the system operator for that tariff model,
- calculation of electricity consumption and peak power is made for each metering point,
- financing for the network development is provided from the revenues and fees for connection to the network and for increasing the connection power, paid by customers and manufacturers
- the tariff for excess reactive energy is the same for all voltage levels,
- the ratio of the higher daily tariff item (HT) to the lower daily tariff item (LT) for the electricity taken over for two-tariff customer categories is approximately 2: 1.

One of the important factors and preconditions for applying this method is the investment plan for transmission and distribution network development in the upcoming regulatory period.

The following tables show the average prices for electric power transmission and electric power distribution for the period 2014 - 2018 by end customer category. The amounts of the average prices of electricity are determined according to the realised income by end customer category, obtained by applying the appropriate tariff items from the tariff systems for electric power transmission and electric power distribution and realised electricity consumption.

Table 5.84 **The realised average price for electric power transmission in the period 2014 - 2018 (lp/kWh)**

Power					
End customer category	**Average price for transmission**				
Commercial - high voltage customers	7.0	7.1	6.6	6.7	7.2
Commercial - medium voltage customers	7.9	7.8	7.7	7.6	7.6
Commercial - low voltage customers	8.9	8.9	8.9	8.9	9.0

The Croatian Transmission System Operator Ltd. ten-year network development plan 2020 – 2029 provides details of all investments in the Croatian transmission network in the framework of regional and European integration. The Development Plan is in full compliance with the ENTSO-E TYNDP 2018 (Ten Year Network Development Plan) proposal, as HOPS is a full member of ENTSO-E.

The following projects are nominated for the ENTSO-E TYNDP 2020:

- Upgrading of existing 220 kV lines between HR and BA to 400 kV lines - 2032-2033
  - Upgrading of existing 220 kV line between SS Dakovo (HR) and TPP Tuzla (BA) to 400 kV line
  - Upgrading of existing 220 kV line between SS Dakovo (HR) and Gradacac (BA) to 400 kV line
  - Upgrading existing 220 kV SS Dakovo to 400 kV
  - New double 400 kV line between SS Dakovo and location Razbojiste
  - Upgrading of existing 220 kV line between SS Gradacac (BA) and TPP Tuzla (BA) to 400 kV line
  - Upgrading existing 220 kV SS Gradacac (BA) to 400 kV
- New 400 kV interconnection line between Serbia and Croatia - 2035
  - New 400 kV overhead line Sombor (RS) - Ernestinovo (HR)
- Slovenia-Hungary/Croatia interconnection - 2021
  - Double 400 kV OHL Cirkovce(SI)-Heviz(HU)/ Zerjavinec(HR)
- CSE1 New - 2029-2030
  - New OHL 400 kV Banja Luka - Lika
  - New OHL 400 kV Lika - Melina
  - New OHL 400 kV Lika - Konjsko
  - New Substation 400/110 kV Lika
- Croatian south connection - 2035
  - New 400 kV substation interpolated in existing 400 kV line Konjsko - Mostar
  - New 400 kV substation for connetion of new generation and increase of security of supply in the southern area near city of Ploce
  - Double 400 kV line connecting SS ZONE 5 and ZONE 6
  - Double 220 kV line connecting SS ZONE 6 and SS Plat
  - Construction of two addiotional OHL bays for connection of OHL 220 kV ZONE 6 - Plat

In accordance with the procedure and as foreseen by European regulations and the European Commission the following Croatian projects are on the fourth PCI list:

- 3.9.1 Interconnection between Žerjavenec (HR)/ Hévíz (HU) and Cirkovce (SI)

Renewables

Total consumption of renewables in 2018 amounted to 414 ktoe (share of 4%). The total consumption of renewables increased from 2013 by 17.3% yearly, with 2017-2018 increase amounting to 7.5%. If biomass and large hydro power are included in the renewables, then the total consumption of renewable energy sources (RES) rises to 3,284 ktoe (with a share of 34%), which position RES to the first place in total primary energy supply mix in 2018 (consumption of liquid fuels is slightly smaller).

However, the share of renewables in the final energy consumption is much smaller amounting just to 0.3% (21.5 ktoe). Consumption of renewables in the final energy consumption increased from 2013 by 7.4% yearly, with the 2017-2018 increase amounting to 2.3%. If biomass is calculated together with the other renewables, then the consumption of RES in the final energy consumption is 1,146 ktoe, which increases the share of renewables in 2018 to 17%. Croatia's energy policy is set in an Energy Act where a basis for the utilisation of renewable energy is mentioned. The objectives for 2020 are set in the Energy Strategy, which was adopted in 2009 and in the national action plan for renewable energy sources, which adopted in 2013. The production of electricity from RES is promoted through a feed-in tariff and loans system. The Croatian Bank for Development and Reconstruction and the Fund for Environmental Protection and Energy Efficiency operate a loan scheme for RES-E projects.

In October 2013, the Croatian government adopted a national action plan for RES until 2020 which shifts the focus from encouraging wind farm construction to energy production from biomass, biogas, cogeneration plants and small hydroelectric power plants (SHPP), reducing the total incentive costs. The plan is in line with the European Union directive on renewable sources, which contains measures through which member countries must ensure 20% of renewables in energy consumption by 2020. To meet the EU goal, the government wants to encourage SHPP, biomass and biogas because these projects have the biggest impact on the economy. The National Action Plan for the production of energy from RES defined targets for three sectors: electricity sector, transport sector and the heating and cooling sector.

Pursuant to the revised programme, the new shares for 2020 have been calculated as follows:
- 39.0% share of RES in gross final consumption of electricity;
- 10.0% share of RES in gross final energy consumption in transport;
- 19.6% share of RES in gross final energy consumption in heating and cooling.

The main national support measures, in the form of economic and financial mechanisms to promote the use of renewables, are:
- Guaranteed purchase prices (feed-in tariffs) for the generation of electricity from renewable energy sources.
- Promotion of biofuel production.
- Promotion of the use of RES and energy efficiency using funds provided by the Environment Protection and Energy Efficiency Fund (EPEEF).
- Promotion of the use of renewables and energy efficiency through the Croatian Bank for Reconstruction and Development (CBRD).

In 2015, the act on RES and efficient cogeneration was adopted by the Parliament. The purpose of this Act is to promote the production of electricity from renewable energy sources and high-efficiency cogeneration, to promote the production of electricity from renewable energy sources and high-efficiency cogeneration at the point of consumption, to increase the share of total direct energy consumption produced from renewable energy sources by using incentive mechanisms and regulatory framework for the use of renewable energy and high-efficiency cogeneration.

Croatia's Energy Act was revised in 2018

Table 5.86 provides estimated data on installed capacities for heat generation from renewable energy sources (RES-H) and statistical data on installed capacities for electricity generation from RES (RES-E) for 2018.

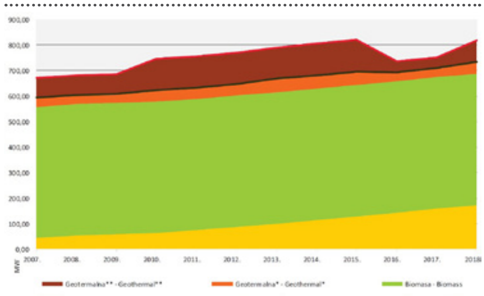
Table 5.86 **Installed capacities for heat and electricity generation from renewable energy sources in Croatia for 2018**

RES	Installed heat capacity (MW)	Installed power capacity (MW)
Solar	172.2	67.7**
Wind	0	586.3
Biomass	515*	64.8
Biogas		50.6
Small hydro power plants	0	38.78
Geothermal	45.6 / 84	10
TOTAL	732.8/816.8	818

* estimation
** systems connected to the grid
Source: EIHP

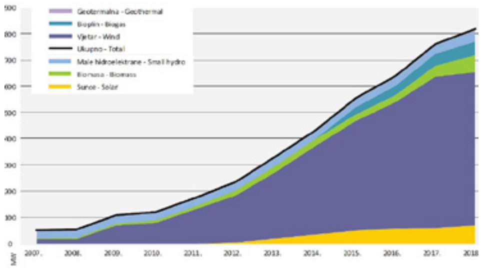
Installed power capacity of photovoltaic systems differs from the value provided by HROTE as it refers to grid-connected systems including autonomous PV systems. Installed capacity of autonomous PV systems that supply facilities without grid connection (lighting houses, holiday houses, GSM bases, parking machines etc.) is estimated at 8.5 MW.

Figure 5.65 **Installed capacities for RES-H generation in Croatia**



* geothermal heat for space heating
** including geothermal heat for hot water and bathing
Source: EIHP

Figure 5.66 **Installed capacities for RES-E generation in Croatia**



Source: EIHP

All existing renewable energy projects and new ones, are registered in the Register of projects and plants for the use of renewable energy sources and cogeneration and of eligible producers (OIEKPP Registry). Registry records data on the project holder, the eligible producer of electricity and the plant, including information on the location and type of facility, technical and technological characteristics and conditions of use depending on the applied technology, basic operating data (installed power plants and planned power generation and heat), and other data derived from preliminary project approvals, the preliminary decision and the decision on the status of eligible electricity producer (location, geodetic points, deadlines, duties, etc.).

Table 5.87 **Overview of registered RES projects entered in the Registry**

Plant category	Number	Installed Electricity capacity [MW]	Thermal capacity [MW]	Contracted subsidised capacity [MW]
Solar power plant	3,782	307.5273	0	53.4
Hydro power plant	49	1676.3490	0	5.9
Wind farm	47	2021.4500	0	585.8
Biomass power plant	119	218.3180	290.4700	73.7
Geothermal power plant	2	20	0	10
Biogas powerplant	64	69.5010	31.8660	42.7
Landfill and wastewater treatment gas power plant	7	9.5990		2.5
Cogenerations	12	1068.9930	180.7800	113.3
TOTAL	4,082	5,392	503	887.3

Source: EIHP

It should be noted that not all solar power projects are registered. Out of 5392 MW of registered renewable electricity capacity, 16% is actually producing and is receiving subsidies from HROTE.

Energy Efficiency and Cogeneration

National targets

The latest energy efficiency targets are summarized in The Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050 and in the Integrated National Energy and Climate Plan for the period 2021-2030.

According to the Energy Development Strategy, increasing energy efficiency is the most important mechanism for reducing energy consumption and one of the fundamental principles of energy transition. Increasing energy efficiency is necessary in order to ensure affordable energy. It is envisaged to increase energy efficiency in all areas of consumption and throughout the production chain from generation, transmission and transport, distribution and consumption. All methods of reducing consumption from legislation, the application of standards and norms, the replacement of plants and devices to the prohibition of using inefficient devices will be applied.

The building sector intends to intensify the application of good practices for energy renovation in all buildings (residential and non-residential) by directing renovation to the nZEB standard (almost zero energy buildings), which also implies stronger utilization of RES (photovoltaic systems, thermal solar collectors, biomass boilers, heat pumps). In the period up to 2030, the transport sector will focus on building new infrastructure for the use of alternative forms of energy in transport (LNG and CNG/CBM, electricity and hydrogen). It is envisaged to increase the share of alternative-powered vehicles, especially electric ones, as well as the electrification of urban and interurban transport, as well as increase the use of LNG in heavy freight, maritime and rail transport. With the development of advanced networks, it is necessary to enable the participation of the transport sector in the cost-effective provision of services of flexibility and balancing of the electricity system. In addition to the development of alternative fuels, activities to stimulate intermodal and integrated transport at national and local levels are also needed.

In addition to sector-specific measures, the development scenario also takes into account the effects of regulatory measures that will have cross-sectoral effects. First and foremost, this refers to the establishment of a functional system of energy efficiency obligations for energy suppliers, in accordance with the current legislative framework of the EU and the Republic of Croatia. It is expected that this mechanism will help achieve major progress in improving energy efficiency in all sectors of direct consumption, through innovative market mechanisms that engage private capital of both suppliers and other players in the energy services market.

It is expected that the transmission losses will stay at the same level in electricity transmission, while it is expected that electricity distribution will further reduce technical losses below the EU average by 2030.

Energy efficiency in the Republic of Croatia is regulated by the following Acts and Codes:

- Energy Efficiency Act (OG Nos. 127/14, 116/18).
- Building Act (OG Nos. 153/13, 20/17, 39/19).
- Act on Protection against Light Pollution (OG No. 14/19).
- By-laws that follow from these Acts.

The national targets for increasing energy efficiency by 2020 are defined in the 3rd National Energy Efficiency Action Plan (NAPEnU) 2014-2016 and revised in the 4th NAPEnU until the end of 2019. The indicative national target for the increase in energy efficiency, expressed as the absolute amount of final energy consumption in 2020 is 6.96 Mten. The corresponding target expressed as the absolute amount of primary energy in 2020 is 10.71 Mten.

Table 5.88 **Indicative national energy efficiency targets in 2030**

Targets 2030	Mten
Primary energy consumption	8.23
Final energy consumption	6.85

Source: Croatia's National Energy and Climate Plan

After 2020, in accordance with the Technical Regulation on Rational Use of Energy and Thermal Insulation in Buildings, all newly constructed buildings should be nearly-zero energy (nZEB). It is expected that the total residential stock will grow at an average rate of approximately 6,600 residential units from 2021 to 2030, 6,300 from 2031 to 2040 and 6,050 units from 2041 to 2050. In order to achieve this growth of the total stock, 10,930,698 m² of new buildings and 8,630,863 m² of renovated buildings are expected in the period from 2021 to 2030 (around 30,000 new and renovated housing units per year, with a very high rate of abandonment and demolition of old poor-quality units of about 11,200 units per year). From 2031 to 2040, the area of newly-built residential buildings will amount to 14,721,602 m², with 9,022,863 m² of renovated residential buildings. This area of renovated buildings per year corresponds to an annual rate of renovation of 1.6%, with a gradual increase from 1% in 2021 to 3% in 2030.

The average final energy consumption in the residential sector will be 30 kWh/m² for newly-built and renovated buildings, and it is expected that there will be no significant variations for the non-residential sector.

It should be noted that, pursuant to Article 2a of Directive 2018/844 amending Directive 2010/31/EU on the energy performance of buildings, the Republic of Croatia will adopt a new long-term strategy for promotion of investments in the renovation of the national building stock, with a plan of measures and indicators for 2030, 2040 and 2050, which will be aligned with the Energy Development Strategy of the Republic of Croatia.

A total of 13.8 million m² of useful heated area of public sector buildings was recorded in the Republic of Croatia in 2010, according to the data from the National Information System for Energy Management. In order to meet the obligation to renovate 3% of the total floor area of heated and/or cooled buildings owned and managed by the central government, in the period until 2020 the Republic of Croatia has chosen an alternative approach, i.e. it has set the target of 117 toe per year in equivalent savings. This approach will also be applied in the period until 2030.

Incentive-based initiatives in the building sector

The key document for the energy efficiency in the building sector is the Long-Term Strategy to Encourage Investment in the Renovation of the National Building Stock of the Republic of Croatia by 2050, which promotes the need to invest in the building stock. The revised strategy aligns the renovation objectives with the NECP in light of demographic trends and activities in the construction sector, with trends of accelerated abandonment of the existing building stock of poorer properties and gradual growth in new construction. The current energy renovation rate of 0.7% per year will gradually rise to 3% over the 2021-2030 period, with a 10-year average rate of 1.6%. An important element is the introduction of additional measurable indicators of energy renovation of buildings, which will strengthen the process of conversion of the stock into nearly zero-energy buildings, i.e. climate neutral.

Energy management and heat preservation is one of the fundamental building requirements. The Technical regulation on the rational use and heat retention of buildings (OG No. 128/15, 70/18, 73/18, 86/18) stipulates the minimum energy performance for new buildings and buildings undergoing major reconstruction, the manner of determining the energy performance of the building, preparation of the study on the use of alternative energy systems, and requirements for nearly zero energy buildings.

Obligation of regular inspections of heating systems and cooling or air conditioning systems in buildings and energy certification of buildings will be put in place by implementing ordinance on energy audit of buildings and energy certification (OG No. 88/17); Ordinance on control of energy certificates of buildings and reports on regular inspection of heating and cooling or air conditioning systems in buildings (OG No. 73/15); Ordinance on persons authorized for energy certification, energy audit of buildings and regular inspection of heating and cooling or air conditioning systems in buildings (OG No. 73/15, 133/15).

Amendments to the Building Act are currently underway in order to address the adoption and implementation of the new Long-Term Strategy of Renovation of the National Building Stock by 2050, promoting electromobility through the installation of infrastructure for charging electric vehicles in buildings and on parking lots adjacent to buildings, simplifying regular controls of heating and cooling or air-conditioning systems in buildings, setting up and supervising technical systems for buildings, defining requirements related to the installation of self-regulation devices, building automation and management systems, as well as changes to the system of issuing authorizations for energy certification of buildings.

It is estimated that in Croatia there are about 50 million m² of useful floor space of apartment buildings, which account for more than 42.3% of total energy consumption. Most of these buildings were built before 1987 and did not have adequate thermal protection and approximately consume 200-250 kWh/m² of heating energy.

In the period from 2014 to 2016, the programme for the promotion of integral renovation of apartment buildings was financed by the funds raised in auctions and implemented through the Environmental Protection and Energy Efficiency Fund; at the end of 2016, the Ministry of Construction and Physical Planning issued a call for applications and allocated HRK 539.23 million (€71.83 million) for energy renovation of 556 buildings; it is estimated that all projects within the framework of this programme will be completed by the end of 2023. A new call for energy renovation of apartment buildings is planned by the end of 2019. Grant funds would be secured from an allocation earmarked for energy renovation of family houses.

In the period from 2014 to 2016, the Programme for Energy Renovation of Family Houses 2014-2020, was financed by national funds raised from auctions through the Environmental Protection and Energy Efficiency Fund; the ERDF funds available under OPCC amount to HRK 200 million (€26 million), but due to complex procedures, these funds are not expected to be utilized for energy renovation of family houses - the plan is to reallocate them for energy renovation of public and apartment buildings, whereas from 2019 onwards this Programme will continue to be co-financed by the funds collected from the sale of emission allowances in auctions, through the Environmental Protection and Energy Efficiency Fund (EPEEF).

In the public sector ERDF (European Regional Development Fund) funds within the OPCC amount to €211 million, are available for energy renovation of public sector buildings, and so far around HRK 1,499 billion have been awarded for energy renovation of 866 buildings; the projects within this programme are expected to be completed by the end of 2023. A FI ESIF energy efficiency loan for public buildings in the amount of HRK 190 million (€25 million) is also foreseen.

Cogeneration: Regulatory framework, installed capacity

There are several large and small cogeneration units operating in Croatia. The most important large cogeneration units are operating in the Zagreb (EL-TO Zagreb and TE-TO Zagreb), Osijek (TE-TO Osijek) and Sisak (TE Sisak) suppling local district heating with heat and simultaneously producing electricity.

Larger industrial cogeneration plants are located in Belišće d.o.o. Belišće, Petrokemija d.d. Kutina, INA Rafinerija nafte Rijeka, at sugar refineries and natural gas processing plants in Croatia.

Indicators of the potential high-efficiency cogeneration and efficient district heating and cooling are taken from the document "Programme for use of efficiency potential in heating and cooling for the period 2016-2030", which was published in November 2015, and which was prepared for the Ministry of Economy (today under the Ministry of Environment and Energy) in accordance with Article 14, paragraph 1 Directive 2012/27/EC.

The established overall (theoretical) potential for high-efficiency cogeneration plants in the Republic of Croatia is estimated with the help of two scenarios concerning the shares of future consumers of DHS coupled with high-efficiency cogeneration: conservative and optimistic. Scenarios are based on the share of consumers of district heating systems that are assumed, based on the determined existing trends (conservative scenario), or optimistic assumptions of positive changes in the economy of the Republic of Croatia (optimistic scenario). Indicators of the potential for use in high-efficiency cogeneration and efficient district heating and cooling are presented in Table 5.89.

Table 5.89 **High-efficiency cogeneration and efficient district heating and cooling Potential**

Indicator	Unit	Conservative scenario, 2030	Optimistic scenario, 2030
Total heat demand (theoretical heat demand for 2030)	ktoe MWh	437 5,086,907	716 8,328,369
Required heating capacity (theoretical)	MWt	3,178	5,262
Share of DHS consumers	%	30.1	55.0
Equivalent heat demand	ktoe MWh	132 1,529,591	397 4,618,222
Equivalent thermal capacity	MWt	956	2,903
Potentially produced electricity	ktoe MWh	207 2,403,643	624 7,257,206

Source: Programme for use of efficiency potential in heating and cooling for the period 2016-2030", Ministry of Economy, November 2015

Cogeneration is regulated by the Act on Renewable Energy Sources and Highly Efficient Cogeneration ("Act") (Croatian Official Gazette nrs. 100/15, 111/18). The use of renewable energy sources and high-efficiency cogeneration is of interest to the Republic of Croatia.

Highly efficient cogeneration in cogeneration plants provides primary energy savings of at least 10%, compared to the reference separate production of electricity and heat. That provides primary energy savings in the case of a cogeneration plant with installed electrical connected load smaller than 1 MW and meets the efficiency and the use of heat according to the new regulation whose contents are defined in Article 25 of the Act.

The main novelties introduced by the new Act related to cogeneration are:

- Changing the model of incentives. Instead of the feed-in tariff system, a new concept of market premium model is introduced.
- The Act stipulates that electricity suppliers are obliged to buy from the operator a certain proportion, expressed as a percentage of the net electricity supplied by eligible electricity producers. The share is determined by the government of the Republic of Croatia by an ordinance which it adopts by 31 October of the current year for the following year. The remaining share of the total net electricity supplied by eligible producers is sold by the operator on the electricity market in a transparent and impartial manner.
- Regulate the status of eligible electricity producer in order to eliminate inconsistencies in the process of issuing, revoking and amending the decision on acquiring the status of eligible electricity producer.
- The obligation of the Ministry to adopt state aid programs for stimulating the production of electricity from renewable energy sources and high-efficiency cogeneration is being regulated in order to adopt programs in accordance with the applicable rules on state aid for environmental protection and energy.
- The system of guarantee of origin for electricity is regulated. The system of incentives is regulated by prescribing the right of appeal to the participants of the tender against the decision of the operator on the selection of the most favorable bidder in the tender for award of market premium and tender for the incentive with guaranteed purchase price, in order to enable the participants of the tender legal protection and control of legality of the competition.
- The issues of collecting and calculating incentive payment funds are regulated in order to prescribe the possibility of raising funds for payment of incentives from the sale of guarantees of origin of electricity produced in the production facility of eligible producers in the incentive system.
- Issues regarding the take-over of electricity from end-users with their own production are regulated in order to prescribe the different values of electricity that the electricity suppliers take from the end-customers with their own production, depending on whether they are the end-customer with their own production from the category enterprise or household.
- The new Act prescribed that government of Republic of Croatia will regulate in detail the issues of classification of production plants, the methodology for determining the share of energy from renewable energy sources in total direct consumption, the status of eligible electricity producer, the system of incentives for the production of electricity from renewable energy sources and the compensation of members of the EQF balance group.

Energy Investment Outlook

The elaboration of the Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050 was preceded by a detailed analysis of all the energy sectors and the necessary investments were identified for each of the sectors which are necessary to achieve the objectives of the strategy. The investment indicators for the adopted S2 scenario are presented below.

Estimation of investment in construction of new power plants (electricity production)

An estimate of the total investment in the construction of new power plants in the period from 2020 to 2050 is presented in Table 5.90.

Table 5.90 **Power plant investments 2020.-2050. (million €)**

Plants type	Investment
Wind	2,297.3
Solar	1,792.1
Heat pumps and electricity in DH	24.9
Storages	219.5
Hydro	1,285.4
Gas	1,026.9
Biomass	247.3
Geothermal	197.8
TOTAL	7,091

Source: Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050

The investments shown also include investments in technologies which are not related to power plants, such as large heat pumps for CTS and battery use. Of the total €9.18 billion, or an average of €306 million per year, power plants account for €8.91 billion or around HRK 66 billion (HRK 2.2 billion annually).

The intensity of investments increases towards the end of the period, as emissions need to be reduced more. At the same time, a relatively strong reduction in specific investments in particular technologies, especially PV and WP projects, is assumed. Analysis of the inter-competitiveness of technologies indicates that by 2030 it will be necessary to maintain some support mechanism for the use of cleaner technologies. Current price developments in the emission permits market indicate that certain RES technologies will soon be priced competitively with conventional technologies (at project level). The area where the greatest contribution from the state and regulatory bodies is expected is to create the conditions for the adoption and integration of new technologies into the system, in the technical and commercial / market sense.

Estimation of investments in the electricity transmission network

Preliminary estimates indicate that total investments in the transmission network (including connections to new conventional power plants, wind, solar and other power plants) would amount to HRK 7.9 billion (€1.05 billion) by 2030, assuming equal annual investment, which would mean an investment cost up to HRK 666 million /year (€87 million/year).

In addition to the financial resources needed to cover the costs of building the transmission network, it is also necessary to provide financial resources for balancing the system (through the balancing mechanism and partly through the electricity transmission fee), or for the procurement of a part of the ancillary services of the system (primarily frequency and power regulation), which can be estimated at up to HRK 375 million /year (€50 million/year) on a preliminary basis, based on existing P/f regulatory reserve prices and the energy prices produced in the regulation.

In the period from 2030 to 2050 preliminary estimates indicate that total investments in the transmission network would amount to HRK 9.9 billion (€1.32 billion), assuming equal annual investments, this would mean an investment cost of up to HRK 494 million /year (€66 million/year).

Costs to balance the system (the procurement of a part of the ancillary services of the system), for 2030 to 2050 period, can be roughly estimated at up to HRK 330 million/year (€44 million/year), based on the assumption of reducing the average error of planning for the production of wind power plants to 2% of installed capacity, and the existing prices of P/f regulatory reserves and the prices of energy produced in the regulation.

Estimation of investments in the electricity distribution network

By analysing the current state of the distribution network and the improvements achieved in the previous 20-year period, it is necessary to invest up to HRK 30 billion (€4 billion) in development of the distribution network, i.e. up to HRK 1 billion (€ 0.13 billion) a year will be sufficient during the observed period.

The priorities for investments in the distribution system are as follows:

a. by 2030 - advanced measurement system by 2025 and advanced network pilot projects,
b. by 2040 - advanced network (Phase I: modernization and automation, advanced network control and management features),
c. by 2050 - advanced network (Phase II: integrated adaptive change-optimized distribution system, optimized for resources with active involvement of network users, system capable to prevent crises).

This level of investment presupposes the stimulation of electricity production in the distribution network consumed at the site and coincides with the consumption of electricity ("balancing of production and consumption").

Assessment of investments in district heating systems

Investments in district heating systems in the forthcoming period primarily relate to investments for the replacement of existing heat networks with reduced losses and related investments in control and management systems, both on the part of the network plant and on the part of demand management (end-user). An additional 50 km of networks are assumed to be built by 2050.

Total investments between 2020 and 2050 are expected to amount to HRK 1.8 billion (€240 million).

Assessment of investments in the natural gas system

The development of the gas supply system in the short term relates to the needs of ensuring security of gas supply and meeting the N-1 criteria, ie construction of LNG terminal, interconnections related to LNG terminal, peak UGS Grubišno Polje, potentially development of IAP pipeline and increase of interconnections capacity with Slovenia, and construction 50 and 75 bar pipelines to increase the internal security of gas supply.

In the medium term, development will be based on an increase in the capacity to import and transport gas to neighbouring countries. In the long term, major renovation of the existing 50 bar system will be required. The development of new interconnections with neighbouring countries (BiH, Serbia) will depend on economic viability.

Total investment for the development of short- and medium-term systems is estimated at a minimum of HRK 10 billion (€1.33 billion) and more. This investment will significantly increase if pipelines for significant transit of LNG, Caspian or Eastern Mediterranean gas can be developed.

Assessment of investments in the oil and petroleum products sector

Investments in the oil sector primarily relate to investments in exploration of new hydrocarbon reserves, with the aim of increasing domestic oil and gas production, or extending the commercial production of hydrocarbons to 2050, and investing in the modernization of refining capacities in order to ensure the competitiveness of domestic production of petroleum products.

Total investments in the renewal of reserves and the modernization of refining capacities in the period from 2020 to 2050 are estimated at:

- hydrocarbon exploration - HRK 37.5 to 112.5 billion (€5 to 15 billion),
- modernization of refining - HRK 3.5 billion (€470 million).

Assessment of investment in the renovation of building stock and other energy efficiency measures

The most significant contribution to reduction of energy consumption is the energy renovation of buildings. In the household sector 10,000 housing units are projected to be renewed annually. In the services sector, the specific heating needs of the total building stock in 2050 are projected to be 55 kWh/m^2 per year. This roughly represents renovation of the existing building stock eligible for renovation at an annual rate of 1.6%.

The total investment cost of energy renovation of buildings is calculated using the present values of assumed renovation prices up to nZEB standards (nearly-zero energy buildings). For residential buildings the price is 1,500 kn/m2, while in non-residential buildings it is 2,500 kn/m2, due to the existence of more complex technical systems in such buildings. The calculation results for both scenarios are shown in Table 5.91.

Table 5.91 **Assessment of investment in the renovation of the building stock**

Period	2021-2030	2031-2040	2041-2050
Residential buildings [million m^2]	8.71	9.11	9.50
Non-residential buildings [million m^2]	4.88	4.88	4.88
Investment residential and non-residential [billion HRK]	13.06 (€1.74 billion)	13.66 (€1.82 billion)	14.25 (€1.9 billion)
TOTAL [billion HRK]	40.97 (€ 5.46 billion)		

Source: Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050

The achievement of the objectives will also be significantly influenced by the construction of new buildings, which, by virtue of the legal obligation from 2021 onwards, must be in the nZEB standard. Given that this is a regulatory measure, it does not need to anticipate financial incentives, but nevertheless an estimate of the necessary investments has been made, which will mostly come from the private investment.

Table 5.92 **Investment assessment for nZEB new construction**

Period	2021-2030	2031-2040	2041-2050
nZEB new construction [million m^2]	10.93	14.72	15.11
Investment nZEB new construction [billion HRK]	38.26 (€5.1 billion)	51.53 (€6.87 billion)	52.89 (€7.05 billion)
TOTAL [billion HRK]		142.68 (€19.02 billion)	

Source: Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050.

Assessment of investments in infrastructure for the introduction of alternative fuels in transport

An assessment of investment in infrastructure for the transfer of alternative energy sources to transport vehicles and vessels is presented in Table 5.93. Investment costs include the procurement and installation of electricity transfer charging stations (home charging stations, slow charging stations up to 22 kW, 50 kW fast charging stations, over 50 kW fast charging stations), compressed natural gas filling stations (together with compressed biomethane), liquefied natural gas and hydrogen, and the cost of connecting to the electricity grid.

Table 5.93 **Assessment of investment in infrastructure for the use of alternative energy sources in transport vehicles / vessels**

Period	2021-2030	2031-2040	2041-2050
Electricity [million HRK]	247.5 (€32.99 million)	697.0 (€92.89 million)	2211.9 (€294.8 million)
CNG (CBM) [million HRK]	190.0 (€25,32 million)	68.0 (€9.06 million)	115.6 (€15.41 million)
LNG [million HRK]	110.0 (€14.66 million)	68.0 (€9.06 million)	57.8 (€7.7 million)
Hydrogen [million HRK]	18.0 (€2.4 million)	30.6 (€4.08 million)	91.0 (€12.13 million)
Total by period [million HRK]	565.5 (€75.37 million)	863.6 (€115.09 million)	2476.3 (€330 million)
TOTAL [billion HRK]		3.905 (€ 0,52 billion)	

Source: Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050.

The assessment of investment needs for the production of biofuels related to the production of advanced biofuels as listed in Schedule A, Appendix IX of the RED II Directive, and the anaerobic digestion plant of the feedstock in Schedule A, Appendix RED II of the Biogas Production and Purification Plant in Biomethane are presented in the following table.

Table 5.94 **Assessment of investments in infrastructure for the production of advanced biofuels as listed in Schedule A, Appendix RED II of the Directive**

Period	2021-2030	2031-2040	2041-2050
Biodiesel [million HRK]	2,743 (€365.57 million)	275 (€36.65 million)	
Bioethanol [million HRK]	978 (€130.34 million)	218 (€29.05 million)	
AD and purification of biogas into biomethane [million HRK]	6.5 (€0.87 million) (€0.87 million)	51 (€6.8 million) (€6.8 million)	173 (€23.06 million) (€23.06 million)
Total by period [million HRK]	3,727.5 (€497 million)	544 (€72.5 million)	173 (€23.06 million)
TOTAL [million HRK]		4,444.5 (€592.33 million)

Assessment of investments for solar thermal collectors

The cost of the system today is estimated at HRK 5,000 /m^2 (€ 665/ m^2), with an expected reduction to around HRK 4,500/m^2 (€600/m^2), taking into account a 1% reduction in technology cost per year, as well as an increase in GDP and the average wage (i.e. the said cost takes into account the total labour cost and equipment). The estimated investment by 2050 would amount to HRK 9.1 billion (€1.2 billion), with an average annual sales of about 65,000 m^2 of collectors.

Table 5.95 **Estimated investment in solar thermal collectors**

Year	Industry 2050	Households 2050	Services 2050	Total (2019- 2050) 2050	Replacement of existing systems	Total 2050
Final consumption (Mtoe)	0.0217	0.045	0.034	0.1007		
Final consumption (GWh)	252.3	523.3	395.4	1,171.1		
Collector area (000 m^2)	382.4	793.1	599.2	1,774.9	250.0	2,024.9
Investment by 2050 (Billion HRK)	1,721 (€0.23 billion)	3,569 (€ 0.48 billion)	2,696 (€ 0.36 billion)	7,987 (€ 1.06 billion)		9,112 (€ 1.21 billion)

Source: Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050

Assessment of total investments in the energy sector

The total estimated investment for the period 2020-2050 by category is presented in Table 5.96. The total investment in reference Scenario 2 is HRK 133.7 billion (€17.82 billion) or HRK 4.45 billion (€0.59 billion) annually.

Table 5.96 **Estimated total investment in 2020-2050 (excluding the building sector)**

Investment category	TOTAL billion HRK	Annual investments billion HRK/year
Production of electricity	52.5 (€7 billion)	1.749 (€0.23 billion/year)
Transmission of electricity	17.8 (€2.37 billion)	0.593 (€0.079 billion/year)
Distribution of electricity	30.0 (€4 billion)	1.000 (€0.13 billion/year)
Transmission and distribution of natural gas	10.7 (€1.43 billion)	0.357 (€0.048 billion/year)
Oil and gas sector	3.5 (€0.47 billion)	0.117 (€0.016 billion/year)
District heating	1.8 (€0.24 billion)	0.060 (€0.008 billion/year)
Transport sector infrastructure	8.3 (€1.11 billion)	0.278 (€0.037 billion/year)
Solar heating systems	9.1 (€1.21 billion)	0.304 (€0.041 billion/year)
TOTAL	133.7 (€17.82 billion)	4.45 (€0.59 billion/year)

Source: Energy Development Strategy of the Republic of Croatia until 2030 with an outlook to 2050

The largest share of investments relates to the electricity system: HRK 100 billion (€ 13.33 billion), 75% of total investment.

CYPRUS

Cyprus

Economic and Political Background

Cyprus's GDP fell 4.5% year-on-year in the fourth quarter of last year, worsening from the 4.3% contraction recorded in the third quarter. All in all, the economy shrank 5.0% in 2020, contrasting 2019's 3.1% expansion and logging the worst reading since 2013 during the Cypriot financial crisis.

Q4's downturn was mainly driven by a pronounced drop in consumer spending and exports. Household consumption fell 6.4% in annual terms in the fourth quarter, which contrasted Q3's 5.2% expansion. Meanwhile, fixed investment bounced back in Q4, growing 21.5% and swinging from the 5.6% contraction recorded in the prior quarter. Moreover, public spending growth ticked up to 10.1% in Q4 from 10.0% in Q3.

On the external front, exports of goods and services tumbled 28.8%, below the 27.2% plunge tallied in the prior quarter. Conversely, imports of goods and services dropped at a slower rate of 5.3% in Q4 (Q3: -12.8% y-o-y). On a working-day and seasonally-adjusted quarter-on-quarter basis, economic growth slowed notably to 1.4% in Q4 from 8.9% in Q3. Looking ahead, the imposition of a second lockdown in January, followed by softer, albeit still-tight, restrictions in February, is likely weighing on the recovery in the first quarter of the new year. However, conditions are expected to improve - mostly in the second half of the year - in line with vaccination progress, which should bolster domestic activity and allow for the revival of the crucial tourism industry. In addition, incoming EU funds and the ECB's loose monetary policy stance should further support the recovery.

IMF estimates that Cyprus's GDP will expand by 4.7% in 2021, significantly higher than -6.4% in 2020.

Energy Policy

National Energy Policy[1]

The implementation of an energy policy in Cyprus while attaining the climate and environmental targets requires a radical transformation of the energy system over the next decade (2021 - 2030) and, therefore, the implementation of significant

[1] Adapted from information available on the Cyprus National Energy and Climate Plan.

investments in energy infrastructure as well as in energy efficiency. Major investments have been planned and scheduled in renewable energy, transformation of networks and the introduction of smart meters in power distribution, power transmission networks, importing and using natural gas for increasing energy efficiency in power generation, energy efficiency in households, businesses, public sector and water sector, transport infrastructures and sustainable mobility, as well as in technological research.

The national targets for the next decade are specified in detail in the National Climate and Energy Plan (NECP) on a mid-term basis, up to 2030, and should serve as a basis for an ambitious long-term strategy aiming towards the reduction of GreenHouse Gas (GHG) emissions by 2050. Therefore, the decarbonisation dimension is the first and foremost component of the NECP structure.
The NECP elaborates on the five dimensions of the Energy Union, i.e. decarbonisation (which is broken down into two distinct sections: GHG emissions and renewable energy sources), energy efficiency, security of energy supply, internal energy market, and research, innovation and competitiveness.

The main objective of the NECP is to design and plan cost-effective policies and measures that will help to achieve the medium- and long-term national energy and climate goals, will contribute to the economic development of the country and will also respond to the challenge of other environmental goals.

In this context, the main goals set out in the preparation of the national energy planning and the preparation of the NECP are:

- Achievement of national targets for reducing GHG emissions, to increase the participation of Renewable Energy Sources in domestic energy consumption and to achieve end-use energy savings in final energy consumption.
- Enhancement of energy supply security.
- Strengthen the competitiveness of Cyprus' economy.
- Protection of consumers while strengthening their role in the energy system.
- Setup and operation of a competitive internal energy market.

Moreover, the implementation of the above energy policy is formulated by an integrated strategy comprising the following main parameters:

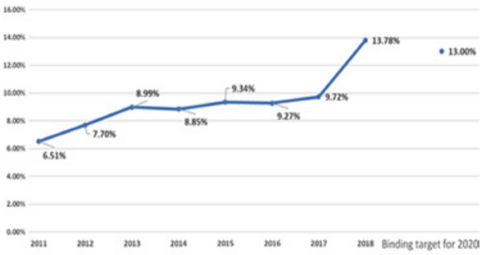
- The liberalization of the electricity market by abolishing the monopoly of the Electricity Authority of Cyprus (EAC) for the generation and supply of electricity through market opening and plans to introduce natural gas for power generation.
- The establishment and operation of centralized import and storage terminals holding strategic and operating oil stocks.
- The implementation of programmes related to the use of energy conservation technologies, the utilization of indigenous Renewable Energy Sources (RES) and the protection of the environment from industrial pollution.
- The promotion of other energy sources which are more efficient and friendlier to the environment, such as biofuels and natural gas.
- The development and exploitation of the country's indigenous energy sources including hydrocarbons.
- Building strong bilateral ties and creating new allies in the region, based on cooperation in the field of energy and resource management, exploitation and exports, in order to take advantage of the synergies emerging from the exploitation of hydrocarbons.

(a) Targets, Objectives & Strategy

The progress of Cyprus in relation to the RES and energy efficiency 2020 targets is presented in Tables 5.97 and 5.98, according to the data provided by the Energy Service of the Ministry of Energy, Commerce & Industry (MECI). According to the preliminary results of 2018 Cyprus has already achieved its binding target for 13% share of RES in the gross final energy consumption and the sectoral RES Heating & Cooling target. This was achieved mainly thanks to the contribution of solar thermal (38% share in RES production in 2018) as well as heat pumps.

Recently there was an assessment of the calculation methodology for the contribution of heat-pumps in the RES Sector. Based on the methodology followed (as defined in Article 5(1)(b) and (4) of Directive 2009/28/EC) there was a significant increase in RES share in heating due to Renewable Energy from heat-pumps [2].

Figure 5.70 **RES share in the gross final energy consumption**



Source: MECI

However, based on current data it does not seem possible to reach the target of RES share in transport and electricity. At the same time, if the large RES electricity (RES-E) projects are implemented on time, the RES-E sectoral target might be achievable by 2020. One of the government measures to achieve the 10% RES share in transport, was the increase of the percentage of biofuels (at 7,3% according to R.A.A. 11/2020) that the suppliers of transport fuels (petrol and diesel) are obliged to blend with conventional transport fuel.

Concerning the national indicative target for primary energy savings (375.000 toe by 2020), this is expected to be achieved. Based on the measures implemented between 2010 - 2016, the primary energy savings during that period accounted to 121.815 toe, or approximately 32,5% of the target. Following the implementation of the additional measures in the 2017-2020 period, the estimated energy savings by 2020 are expected to be 380.815 toe, or approximately 101,6% of the target.

However, the national indicative target for 2020 regarding the primary energy consumption in Cyprus is not expected to be achieved (the target for 2020 is 2.2 Mtoe and the primary energy consumption was 2.5 Mtoe in 2017)[3].

Finally, according to the 4th National Energy Efficiency Plan (NEEP), the mandatory cumulative energy savings target (241.588 toe) for Cyprus for the 2014-2020 period is expected to be achieved by the implementation of the measures included in the NEEP.

Table 5.97 **Progress of Cyprus in relation to the RES 2020 targets**

Sectoral RES Target	Year 2018*	Target by 2020	
Heating/Cooling	37,11%	23,5%	indicative
Electricity production	9,37%	16%	indicative
Road Transport	2,5%	10%	binding
Total share of RES (%)	13,78%	13%	binding

*The results of 2018 are preliminary
Source: MECI

Table 5.98 **Progress of Cyprus in relation to the energy efficiency 2020 targets**

Sectoral RES Target	Year 2018*	Target by 2020
	2017	2020
Indicative target for primary energy consumption (Mtoe)	2,5	2,2
Mandatory cumulative energy savings target for the 2014-2020 period (toe)	68.978	241.588
National indicative target for primary energy savings (toe)	121.815*	375.000

*The data is for 2016
Source: MECI

Regarding the national energy and climate targets for 2030, Cyprus has set quantitative targets, which are presented in Table 5.98. The energy and climate targets present opportunities, benefits and advantages for the national economy, the energy system and civil society, in general, as well as challenges that need to be overcome.

[2] Information available on the Cyprus National Energy and Climate Plan
[3] Information gathered from the 4th National Energy Efficiency Plan (NEEP)

Table 5.99 **Cyprus 2030 Energy & Climate targets**[4]

Greenhouse gas emissions
Emissions in the non-ETS sectors to be reduced by 20,9% compared to 2005.
Emissions in ETS sectors to be reduced by 24,9% compared to 2005
RES in the final energy consumption
Share of RES in gross final energy consumption to reach 23%
Share of RES in gross final electricity consumption can reach at least 26%
Share of RES in heating and cooling to reach 39%
Share of RES in the transport sector to reach 14%
Improving energy efficiency
Final Energy Consumption of 2,0 Mtoe in 2030, representing 13% reduction in final energy consumption*
Primary Energy Consumption of 2,4 Mtoe in 2030, representing 17% reduction in primary energy consumption*
Achieving cumulative energy saving of 243,04 ktoe during 2021-2030

* compared to the respective projection for Cyprus in 2007 in the EU PRIMES 2007 Reference Scenario
Source: Cyprus National Energy and Climate Plan

(b) Sectorial Energy Policy[4]

Table 5.100 presents the key policy priorities for each dimension of the NCEP, which are deemed necessary for attaining the aforementioned objectives (Table 5.99). These policy priorities are the axes for developing specific measures under each dimension.

All these policy priorities and the specific measures resulting from their implementation are part of an integrated plan for the optimal attainment of the national energy, environmental, socio-economic and development objectives, which requires consistency, horizontal combination and coordination in monitoring the priorities and implementing the measures. A key requirement for attaining the objectives set out in the context of NECP is to understand that the progress made in each individual sector automatically affects the progress made in the other sectors. Consequently, the impact of the measures that are finally planned and implemented do not affect just one topic and section of the NECP, but has an impact on the overall development of the energy system.

Table 5.100 **Key policy measures planning priorities**

Pilar	Key policy planning priorities
GHG emissions and removals	• Promotion of natural gas as intermediate fuels for the decarbonisation of the energy system • Promotion of renewable energy sources • Improvement of energy efficiency in buildings, industry and infrastructure • Reduction of emissions in the transport sector • Reduction of fluorinated gas emissions • Reduction of emissions from agricultural sector • Reduction of emissions from waste sector • Increase carbon sinks
Renewable energy sources	• Various RES Support schemes for Self-Consumption • Synergies with other sectors (Energy Efficiency, Waste, Security of supply and Internal Energy Market) to promote RES in all energy sectors • Support schemes for RES to participate in the Electricity Market • Replacement of old Solar Collectors for households • Replacement of Solar Collectors for Commercial purposes and use of Solar Technologies for High process heat and/or Solar Cooling • Old vehicle scrapping scheme and financial incentives for the purchase of electric vehicles (both new and used) • Promotion of the open loop Geothermal Energy • Installation of RES and Energy Efficiency technologies in Public Buildings. • Electricity Storage Installations, Framework development and possible financial incentives. • Various other measures for RES in Transport (New bus contracts (using alternative fuels, electricity, gas, and biofuels B100), Use of Biofuels (and biogas) in Transport Sector • Other indirect measures that will help to increase energy efficiency and thus the RES Share in transport. • Statistical Transfer of Energy to be examined (exporting Energy in case of Electricity Interconnector)

4 Information available on the Cyprus National Energy and Climate Plan

Pilar	Key policy planning priorities
Energy efficiency	• Energy efficiency obligation scheme for energy distributors • Energy Fund of Funds providing soft loans for energy efficiency • Individual energy efficiency interventions and energy efficiency retrofits in governmental buildings • Implementation of information and education measures • Support schemes/incentives for promoting energy efficiency in households, enterprises and wider public • Energy efficient street lighting. • Additional floor space "allowance" for buildings exceeded the minimum energy efficiency requirements set by national law • Advanced Metering Infrastructure Plan. • Promotion of energy efficiency in enterprises, through voluntary agreements • Action plan for increasing energy efficiency the road transport. • Energy efficiency in water sector • Vehicle excise duty based on CO2 emissions • Energy consumption fee for Res and energy efficiency applied on electricity bills. • Excise tax on road transport fuels exceeding the minimum levels by EU legislation
Security of supply	• Introduction of natural gas via LNG imports and the development of the necessary infrastructure • Increasing the flexibility of the national energy system
Internal Energy market	• Promotion of electricity interconnectivity of Cyprus via the project of common interest EuroAsia Interconnector • Development of internal natural gas network pipeline infrastructure • Investments for development and secure operation of the transmission electricity system • Promotion of the necessary regulatory framework and projects for the operation of the competitive electricity market • Promotion of the EastMed pipeline project

Pilar	Key policy planning priorities
Research, innovation and competitiveness	• Fund of funds • New Industrial Policy • Establishment of the Deputy Ministry of Innovation and Digital Transformation • European Structural and Investment Funds in the new Programming Period 2021 - 2027 • Revision of national funds regarding research and innovation with the aim to boost climate and energy priorities

Source: Cyprus National Energy and Climate Plan

Governmental Institutions[5]

This section provides brief information on the key institutions in Cyprus related to energy matters, with an emphasis to their main roles and responsibilities and how these institutions collaborate/fit together. The institutions presented below include: (i) authorities involved with policy making, such as the Ministry of Energy, Commerce & Industry (MECI), the Cyprus Energy Regulatory Authority (CERA), and (ii) energy related organizations involved with policy implementation, such as the Transmission System Operator (TSO), the Electricity Authority of Cyprus (EAC), the Natural Gas Public Company (DEFA), the Cyprus Organization for the Storage & Management of Oil Stocks and the Cyprus Hydrocarbons Company (CHC).

(a) Ministry of Energy, Commerce & Industry (MECI)

The Ministry of Commerce & Industry (MECI) is responsible for the formulation of present policy and monitoring its implementation on matters pertaining to trade, energy, industry and consumers, in such a way that it will contribute positively towards the further development of the national economy and the well-being of the population of the island. In addition, the Ministry supervises/oversees and is associated with the rest of the energy related institutions in Cyprus.

[5] Adapted from information available on the corresponding webpage of each institution/organization.

(b) Energy Service, Ministry of Energy, Commerce & Industry

The Energy Service is a Service that operates under the Ministry of Energy, Commerce, & Industry and has the role of monitoring the implementation of the National Policies related with energy efficiency, energy efficiency in buildings, biofuels and fuels. Also, Energy Service, makes suggestions and recommendations about possible support schemes and mechanisms to promote those topics.

(c) Hydrocarbons Service, Ministry of Energy, Commerce & Industry

The Hydrocarbons Service, operates under the Ministry of Energy, Commerce, & Industry. The main responsibilities of the Hydrocarbons Service are related to the prospecting, exploration and exploitation of hydrocarbons within the territory of the Republic of Cyprus, not only at a regulatory level but at an operational level as well, and for strengthening the geostrategic role of Cyprus in the region.

(d) Cyprus Energy Regulatory Authority (CERA)

The Cyprus Energy Regulatory Authority (CERA) is an independent authority responsible for the regulation of the electricity and gas markets, with exclusive rights to issue licenses for all activities and infrastructure relating to electricity and gas in the internal energy market, to regulate and approve tariffs, to supervise licensed activities, to resolve disputes, to protect consumers, to secure a reliable energy system, to monitor supply and demand balances in the energy market, and to develop an economically viable and competitive energy market.

(e) Transmission System Operator (TSO) and Distribution System Operator (DSO) for Electricity

The Transmission System Operator (TSO) for Electricity was established in 2003. The functions and responsibilities of the TSO Cyprus are to secure the operation of the Electricity Transmission System and to manage the electricity market on an objective, non-discriminatory basis, in a competitive environment, while at the same time, supporting and promoting electricity generation from renewable energy sources. The TSO Cyprus ensures access to the Transmission System of all producers and suppliers of electricity.The Distribution System Operator (DSO) is designated by the EAC and is responsible for the operation, maintenance and development of the distribution system. The DSO is, moreover, a neutral market facilitator and a catalyst regarding the implementation of new technology such as, for example, smart grids, which provide effective services to all market participants (producers, suppliers, consumers and prosumers) via smart infrastructure and technologies, thus enabling transparent, impartial, fair and non-discriminatory access to the network.

(f) Electricity Authority of Cyprus (EAC)

The Cyprus Electricity Authority (EAC) was founded in 1952. The Electricity Authority of Cyprus (EAC) has been for many years a vertically integrated company (governed by the electricity Law) active in power generation, transmission, distribution and the supply of electricity to consumers in Cyprus. EAC is the Distributor System Owner (IMS) as it is the owner of the distribution system. The EAC is carrying out Operational Unbundling in compliance with the Regulatory Decision of the Cyprus Energy Regulatory Authority (CERA), which implements the corresponding provisions of the EU. Through "operational unbundling", the four "core regulated activities" - the monopoly activities of transmission and distribution and the competitive activities of generation and supply - have become separate operations within the EAC. Operational unbundling ensures that the EAC does not exploit its dominant position and that equal opportunities are offered to private sector producers or suppliers. For the implementation of operational unbundling, the EAC has created independent units for its core regulated activities in such a way as to guarantee their reliable and independent operation.

(g) Natural Gas Public Company (DEFA)

Concerning the development of the internal gas market and network, a Natural Gas

Company, known by its Greek Acronyms as DEFA, has been established and is responsible for the import, storage, distribution, transmission, supply and trading of natural gas, and the management of the distribution and gas supply system in Cyprus (to be established). The council of Ministers of the Republic of Cyprus has issued a decree dated 18/06/2008, which appoints DEFA as the sole importer and Distributor of Natural Gas in Cyprus and directs DEFA to proceed with securing the necessary Natural Gas quantities at the best commercial terms.

(h) Cyprus Organization for the Storage & Management of Oil Stocks

This is the organization responsible for maintaining and managing emergency stocks of crude oil and/or petroleum products as per the relevant obligation as applied to all EU Member States. These stocks have to be available at all times and only the Minister of Energy, Commerce, Industry and Tourism has the right to order the release of part or the whole of the oil stocks in order to deal with shortages in energy supply.

(i) Cyprus Hydrocarbons Company (CHC)

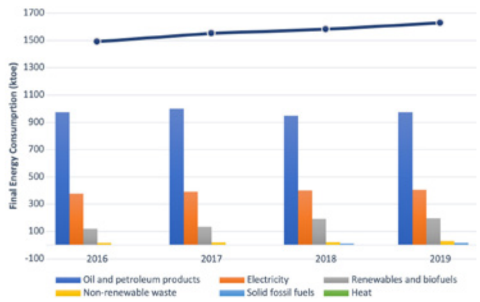
The Cyprus Hydrocarbons Company (CHC), formerly known as the Cyprus National Hydrocarbons Company (CNHC), is entitled with the mission of managing all commercial aspects related with the exploitation of indigenous hydrocarbon resources (i.e. acts as the 'commercial arm' of the government regarding oil and gas exports and the trading/ supply of natural gas).

Energy Demand and Supply

National Energy Demand [6]

The final energy consumption in Cyprus amounted to 1.581 ktoe in 2018, showing an increase of 6% during the period 2016-2018. The level recorded for 2016 and 2017 was 1.552 ktoe and 1.491 ktoe, respectively.

Figure 5.71 **Final energy consumption for the period 2016 - 2019**



Source: Eurostat 2021

In 2018, 60,1% of energy demand was covered by the use of oil and petroleum products, followed by 25,4% the use of electricity and Renewables and biofuels with 12,2%.

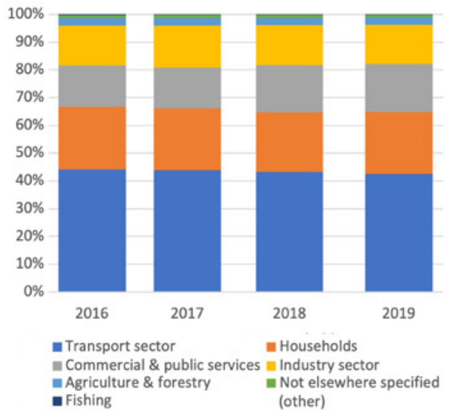
Renewables and biofuels had a 12,2% share (192,6 ktoe) of the final energy consumption in 2018. Respectively, renewables and biofuels had an 8,7% share (135,7 ktoe) in the final energy consumption in 2017 and an 8,1% share (120,2 ktoe) in 2016. The consumption of renewables and biofuels rose by 60,3% in the period 2016-2018.

Electricity consumption increased by 6% in 2018 compared to 2016. This can be attributed to the broad trend for electrification in the economy and mainly on the continued electrification of the heating and cooling sector. In addition, the considerable volume of electricity consumed in the transport sector is expected to have a significant role in the growth of electricity demand in the following years.

The use of solid fossil fuels is still preferred by the domestic cement industry, despite the environmental impact of the combustion of such fuels and the international restrictions in place, primarily due to their competitive prices. A total of 13,6 ktoe of solid fossil fuels were consumed in 2018. The data presented in Figures 5.71 and 5.72 were obtained by Eurostat, and are based on the new methodology of energy balances as applied since April 2020.

6 Statistical data obtained by EUROSTAT (2020). It should be noted that the fuel consumption of international aviation is not taken into account.

Figure 5.72 **Final energy consumption by sector for the period 2016 - 2019**



Source: Eurostat 2021

As shown in Figure 5.72, transport remained the most energy consuming sector in Cyprus with 678,5 ktoe in 2018. Its annual share exceeds 40% of the final energy consumption throughout the three-year period (2016-2018). Residential is also a large energy consuming sector, with a consumption of 337,2 ktoe in 2018. The residential share was 23% in 2016, decreasing to 21% in 2018. In 2016 the energy consumption in the industrial sector amounted to 225,3 ktoe. In 2017 it recorded a sharp increase of 9%, but in 2018 it recorded a 3% decrease, reaching 276,5 ktoe. The other sectors of the economy (i.e. Agriculture & forestry, Fishing) represented an average of just 4% share in the total final energy consumption for the period 2016 - 2018.

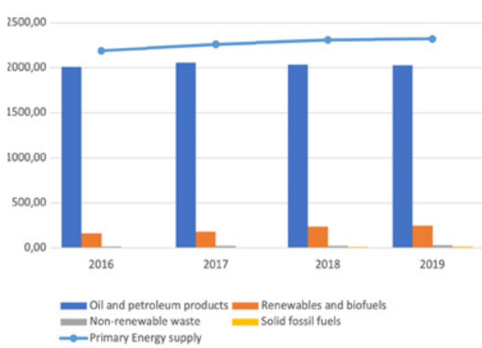
National Energy Supply[7]

Primary energy supply is defined as the national energy production plus energy imports, minus energy exports and international bunkers, then plus or minus stock changes. It should be noted that the consumption of international aviation is not taken into account.

Similarly, as with the case of the final energy consumption, energy supply in the period 2016-2018 was mostly based on oil products (Figure 5.73). The oil and petroleum products share decreased from 91,9% in 2016 to 88.1% in 2018 whereas the share of RES increased by 2,9% in this period (7,4% share in 2016 increasing to 10,3% in 2018). Finally, solid fossil fuels and non-renewable waste constitutes a very small share of the energy supply (0.7% in 2016 increasing to 1.6% in 2018).

Useful insights can be provided through a comparison of the final energy consumption with the primary energy supply. Even though final energy consumption undergoes a moderate increase in the following years, primary energy supply seems to follow a relatively stable trend. This is an indication of an improved energy efficiency that comes from the use of more energy-efficient technologies for heating and cooling and the increase of use of renewable energy technologies. In the following years is anticipated that energy efficiency will be improved as electricity will be generated in more efficient gas-fired plants.

Figure 5.73 **Energy supply (ktoe) from the period 2016 - 2019**



Source: Eurostat 2021

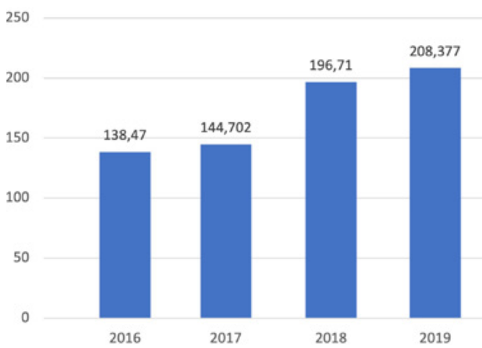
Energy Balance[8]

Domestic primary energy production increased from 138,5 ktoe in 2016 to 196,7 ktoe in 2018, without any radical changes as to the main sources of energy (Figure 5.73). Thus, solar thermal remained the country's main source of indigenous energy, accounting

7 Statistical data obtained by EUROSTAT (2020). It should be noted that the fuel consumption of international aviation is not taken into account.

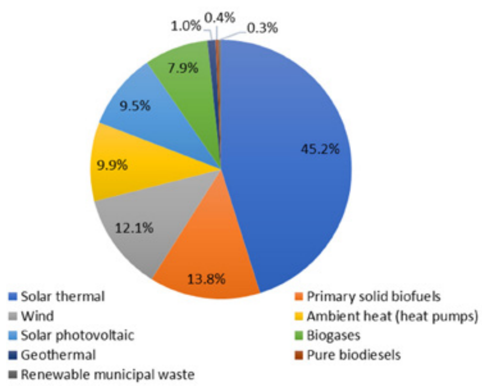
for more than 45% of energy production in the period 2016-2018. Specifically, in 2018, 72 ktoe were produced by solar thermal systems for hot water production. The contribution of solid biofuels and wind farms for the same period were 13,4% and 11,8%, respectively. It is worth mentioning that the share of photovoltaics systems in the same period (2016-2018) increased by 36,7% (from 12,5 ktoe in 2016 to 17,2 ktoe in 2018). Figure 5.74 illustrates the aggregate share of domestic primary energy production for the period 2016-2018.

Figure 5.74 **Primary energy production (ktoe) for the period 2016 - 2019**



Source: Eurostat 2021

Figure 5.75 **Aggregate share of primary energy production for the 3-year period 2016-2018**

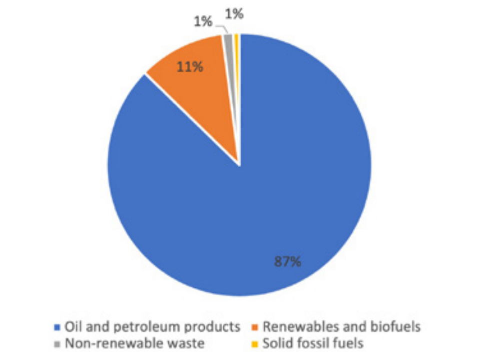


Source: EUROSTAT 2020

Energy Mix[9]

The energy mix continues to be dominated by oil and petroleum products, which contributed by 88.1% of the total energy supply in 2018. Over the period 2016-2018, the share of oil products declined, while the contribution of renewable energy to energy supply has steadily increased reaching 10,3% in 2018 (Figure 5.75). The situation is expected to change in the near future as RES penetration increases and once natural gas from LNG imports becomes available to the local market (replacing oil fuel for the electricity generation and in industry, and in the long term the household sector). It is anticipated that this will be reflected by a relatively large decline in the share of oil products in the energy mix, although the impact will not be that high, since the demand for oil products in the transport sector will continue to be dominant.

Figure 5.76 **Energy Mix for 2019**



Source: EUROSTAT 2021

Energy Dependence [10]

The energy dependency rate shows the proportion of energy that an economy must import in order to meet its energy needs. It is defined as net energy imports (imports minus exports) divided by gross inland energy consumption plus fuel supplied to international maritime bunkers, expressed as a percentage.

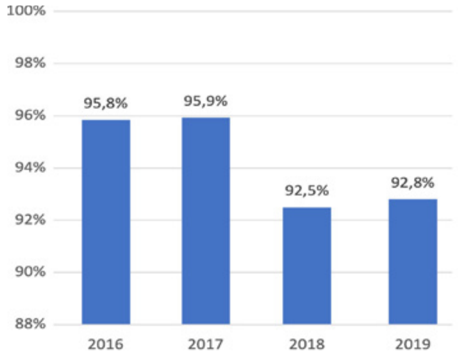
8 Statistical data obtained by EUROSTAT (2020). It should be noted that the fuel consumption of international aviation is not taken into account.

9 Statistical data obtained by EUROSTAT (2020). It is noted that the fuel consumption of international aviation is not taken into account.

10 Statistical data obtained by EUROSTAT (2020).

Due to the country's limited indigenous energy resources, Cyprus is a highly energy dependent, country at a level above the average of the European Union. In the EU in 2017, the average energy dependency was 55%, while in Cyprus this was around 96%. As Figure 5.77 shows, the dependency rate on energy imports has decreased from 96% in 2016 and 2017 to 92% in 2018.

Figure 5.77 **Energy dependency rate for the period 2016-2019**

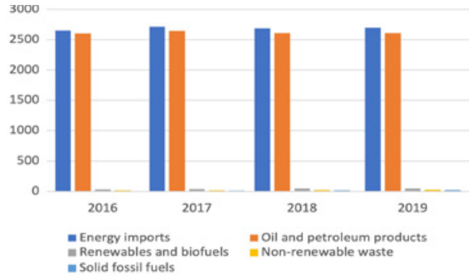


Source: Eurostat 2021

Nevertheless, energy dependence on account of imported oil products is overwhelmingly high as these products also constitute the dominant energy source for all sectors. Specifically, in 2018, oil and petroleum products accounted for 97% of all energy imports, while solid fossil fuels, non-renewable waste and RES & biofuels accounted for the remaining 3% (Figure 5.78).

With regard to the trend of imports by type of energy, the share of oil and petroleum products in the total imports decreased slightly between 2016 and 2018. On the other hand, the share of RES & biofuels imports increased during this period from 1,2% to 1,7%, while Non-renewable waste remained constant.

Figure 5.78 **Energy imports breakdown for the period 2016-2019**



Source: Eurostat 2021

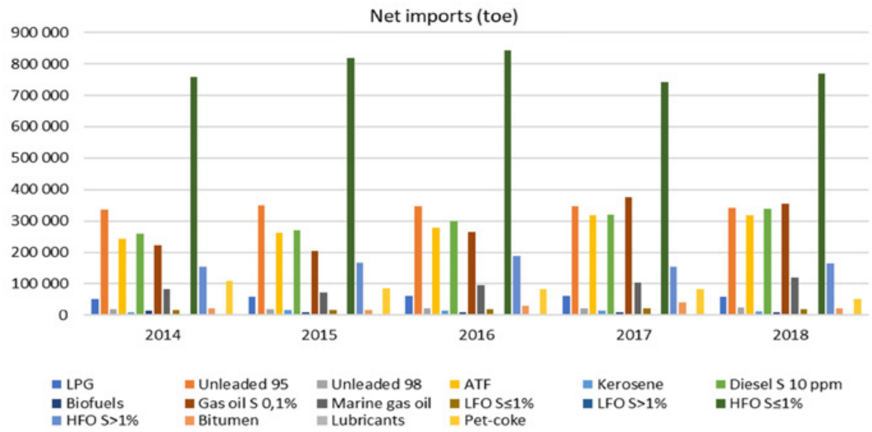
The Energy Market

Petroleum Products

(a) Petroleum products Supply and Demand

In Cyprus the main source of energy is provided by petroleum products, which are exclusively imported. Petroleum products are used for transportation, power generation and space heating and cooking. Cyprus imports around 2,5 million MT per year (2018) of refined oil products, while most of them are imported from neighbouring countries, e.g. Greece and Israel. In particular, the possibility to diversify the current energy supply is very limited because of the small amounts of petroleum products that are imported in Cyprus due to the limited size of the internal market, the lower transport (shipping) costs from neighbouring countries and the availability of petroleum products with the required specifications due to similar climatic conditions.

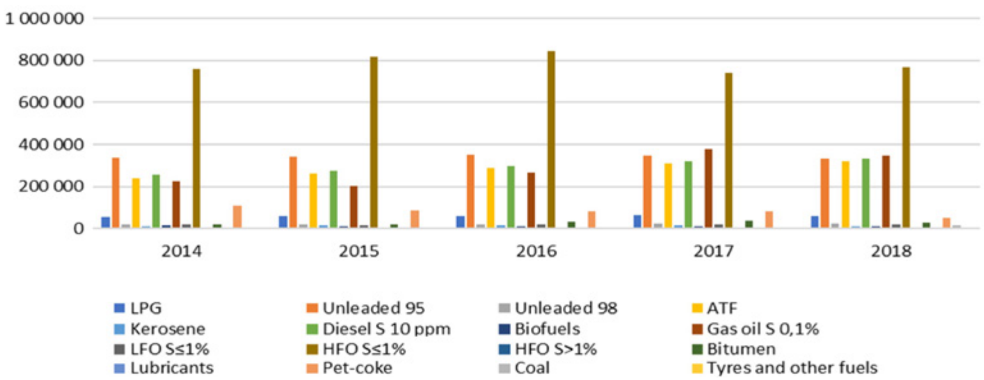
Figure 5.79 **Net imports (toe) of petroleum products for the period 2014-2018**



Source: National Energy & Climate Action Plan 2020-2030

Dependence on the import of petroleum products and a very low rate of utilisation of indigenous energy sources create a framework of reduced security for the uninterrupted supply of energy, and exposure of the economy to the fluctuations of global oil prices.

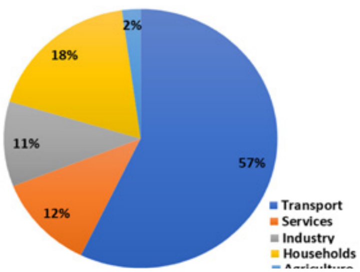
Figure 5.80 **Primary consumption (toe) of petroleum products for the period 2014-2018**



Source: National Energy & Climate Action Plan 2020-2030

The **total final consumption** of oil products in 2018 amounted to 1,78 mtoe (including imports of oil for electricity generation). The oil products were mainly used in the transportation sector, with a consumption of 1,01 mtoe, i.e. approximately 56,7% of the total final consumption of oil products in 2018. Services (including commerce & hotels) consumed 0,21 mtoe, representing 12% of the total oil consumption, agriculture consumed 0,039 mtoe, representing 2% of the total oil consumption, households consumed 0,324 mtoe, representing 18% of the total oil consumption, while the industry consumed 0,189 mtoe, 11% of the total oil consumption in 2018.

Figure 5.81 **Final energy consumption of oil products share per sector (%) of the total final energy consumption**



Source: National Energy & Climate Action Plan 2020-2030

Oil Imports / Dependence

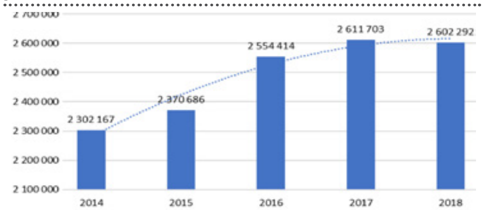
With Cyprus being an 'isolated energy island', it exhibits a high degree of dependence on imported oil products, while the main fuels currently used in power generation are fuel oil and diesel oil. The various oil products imported are used in the transport, households, services, agriculture and industry sectors.

Currently, imported oil products include LPG, unleaded gasoline, jet fuel (ATF - Aviation Turbine Fuel), kerosene, diesel, gasoil, LFO, HFO (mainly used for power generation purposes by EAC), bitumen (used in road asphalt) and pet coke (used for cement production by the Vasilikos Cement Company).

Apart from these, also biofuel blends, marine bunker fuels and lubricants are imported, which have other own applications.

Imports of oil and petroleum products, except HFO (i.e. LPG, gasoline, kerosene, diesel, heating oil, marine gasoil, LFO) constituted 61,5% (1,6 mtoe) of the total oil products imports in 2018, while 13,7% (0,36 mtoe) concerned imports of HFO, which was used almost exclusively for power generation. The import of pet-coke reached 0,05 mtoe (1,9% of total oil-products supply) and the rest amounted to the import of bitumen (0,021 mtoe) for road construction purposes (non-energy use).

Figure 5.82 **Petroleum products imports for the period 2014-2018**



Source: National Energy & Climate Action Plan 2020-2030

c) Upstream Sector-Domestic Production and Exploration

Currently, there is no domestic production of oil or oil products. However, the energy sector of Cyprus is transforming due to new natural gas discoveries within its EEZ. There are strong signals that Cyprus will soon move from exploitation, to exploration and production. The hydrocarbon exploration activities taking place offshore Cyprus do not preclude the possibility of oil findings, while the natural gas reserves already discovered in Block 12 are expected to contain some valuable condensates, which may be converted into synthetic oil.

(d) Downstream and Midstream Sectors Infrastructure (Refineries, Pipelines, Storage, Terminal and Domestic Oil Market)

Sometime ago the government decided the relocation of the oil terminals, including liquefied petroleum gas (LPG), as well as other related facilities from the seafront of

Larnaca area. Based on that decision and subsequent decision to develop the necessary infrastructure for an LNG import terminal, the New Energy and Industrial Area of Vasilikos was established in November 2014. The relocation of the oil products storage except LPG is expected to be completed in the first quarter of 2020 and that of LPG around the end of 2020 early 2021.

The modern and upgraded larger oil storage facilities will help improve the security of supply, since larger quantities of petroleum products could be stored on the island as it will also be possible to unload larger tankers. Alongside with the abovementioned procedures, the Cyprus Organization for the Storage and Management of Oil Stocks (KODAP), the Central Stockholding Entity of Cyprus established by "The Maintenance of Oil Stocks Law of 2003", (N.149(I)/2003), is planning to build its own oil storage terminal in the Energy and Industrial Area of Vasilikos in order to relocate its own oil stocks which are held abroad and in private terminals in Cyprus, as well as, to reduce the annual storage cost.

To this effect KODAP has signed a € 35 million financing agreement with the European Investment Bank (EIB) to finance the construction of a privately owned oil terminal. The privately owned terminal of KODAP will be built at the Vasilikos Energy Center and will consist, at this stage, of six liquid fuel storage tanks with a total capacity of 200.000 cubic meters, pipelines and pumping stations, fire safety and protection systems, as well as buildings. This is another move towards strengthening the security of supply since the majority of the oil stocks will now be kept on the island.

The Cyprus oil market is dominated by 10 local petroleum products trading companies which import and supply oil products in Cyprus for retail, industrial and commercial purposes. Three (3) of them share more than 70% of the market share. After the cease of the operation of the Cyprus Petroleum Refinery in Larnaca in April 2004, these trading companies import finished petroleum products from refineries abroad, store them at their facilities and then distribute them out to the local market through their own network of petrol stations. In 2020 the total number of petrol stations operating in Cyprus was 305.

Automotive and heating fuels are traded in Cyprus through the petrol stations located throughout the country (most of the petrol stations in Cyprus are owned by the aforementioned oil importing companies). Since the accession of Cyprus to the EU, oil products' prices are set freely, while the Minister of Energy, Commerce & Industry has the authority to set a price ceiling for specific oil products and for a specific duration in the event of emergency or during times of intense price volatility.

LPG is currently only used only for domestic, industrial, services (hotels and restaurants) and heating purposes and is sold both in bottles and in bulk. LPG bottles delivery has been imposed with reduced VAT equal to 5%.

The Cyprus Organization for the Storage & Management of Oil Stocks (KODAP) purchases its strategic products through tenders. EAC procures gasoil and HFO through periodic tenders for its own needs in fuel for power generation. The storage facilities for oil products in Cyprus are presented in Table 5.101:

Table 5.101 **Oil products storage terminals/capacity**

Owner/Operator	Type of Facility	Petroleum Products & Tanks	Storage Capacity
Electricity Authority of Cyprus (EAC)	Storage facilities (and Single Point Mooring system for oil imports) at the three power stations of EAC (Vassiliko, Moni, Dekelia), for its own fuel needs (operational and strategic stocks) for power generation	Gasoil	95.000 cubic meters
		HFO	112.000 cubic meters
Electricity Authority of Cyprus (EAC) - stocks of KODAP	1 Tank at Vassiliko	Gasoil	30.000 cubic meters
Cyprus Petroleum Storage Company Ltd (ex. Cyprus Petroleum Refinery Ltd)	Tank farm	Bitumen	10.000 metric tonnes
VTTV Ltd (private company wholly owned by VTTI which was created with a 30% share of Vitol Group)	Storage hub and associated infrastructure (including truck loading facilities) and a jetty for oil import/export	Gasoil (12 tanks for import/export)	287.991 cubic meters
		Heating Gasoil (0.1% sulphur content) ? 1 tank for imports	11.345 cubic meters
		Automotive Gasoil (10ppm sulphur content) - 2 tanks for imports	32.054 cubic meters
		Unleaded gasoline (total of 8 tanks: 5 for import/export and 3 for imports)	138.078 cubic meters
		Gasoline-MTBE (1 tank for import/ export)	10.422 cubic meters
		Jet Fuel (total of 3 tanks: 2 for import/ export and 1 for imports)	62.698 cubic meters
		FAME (a diesel blending agent) - 1 tank	2.038 cubic meters
Petrolina Group (a local Cypriot private company)	Storage terminal (+ truck loading facilities)	Gasoline, Auto / Heating Gasoil, Kero Bunkering fuels Jet fuels bitumen	104.139 cubic meters

Source: Author's research

(e) Security of Supply

The Cyprus Organization for the Storage & Management of Oil Stocks (KODAP), in the context of the relevant EU Directive obligation maintains, oil stocks in Cyprus and Greece, at a level equivalent to 90-days average local consumption. The use of indigenous sources of energy, such as hydrocarbon deposits and RES will contribute towards increasing the flexibility of the national energy system and ensuring the security of energy supply. The promotion of RES and objectives regarding demand response and energy storage can play an important role.

(f) Planned New Projects

Following an official decision, the decommissioning of the existing oil products storage terminal is foreseen, as well as for the relocation of the existing storage facilities of the local petroleum and LPG trading companies. A strategic oil stocks depot will be set up and operated by the Cyprus Organization for the Storage & Management of Oil Stocks (KODAP). As an interim solution, until the finalisation of design & construction of the new fuel farm (KODAP), the stocks being held were transferred to the VTTV terminal, a private fuel tank farm. The new Fuel Farm will be situated on the north/east of the Vasilikos Cement Company, and it will consist of the following: Four (4) tanks of CLASS A (Mogas) products, and seven (7) tanks of CLASS B (Jet fuel, and Diesel) products will be erected, of total storage capacity of approximately 430.000 m3. The tank sizes are identical and are of 45m in diameter and 22m height. Petroleum and LPG storage facilities, for the storage of the operating stocks, is to be operated by the local petroleum and LPG trading companies.

Natural Gas

No internal gas market exists yet in Cyprus, but efforts are underway for bringing gas to the island to be used in the local market for power production but also in due course to cover the demand of tourists and commercial household consumers as well. Regarding indigenous hydrocarbon deposits offshore Cyprus, the Aphrodite natural gas field operator and the Republic of Cyprus have completed negotiations for the Aphrodite Field Development and Production Plan (AFDPP), which was approved in 2019. As a result, an Exploitation License for the production of the Aphrodite Field was issued in November 2019. According to the AFDPP, natural gas production is expected to begin in 2025. The Aphrodite Field gas, is going to be transmitted to Egypt via a subsea pipeline, to the Idku LNG Terminal in Egypt for liquefaction and re-export, as well as for we in the domestic market.

In the framework of the 1st Hydrocarbon Licensing Round held in 2007, an Exploration License for Block 12 was granted to Noble Energy for an initial period of three years and a Production and Exploration Contract (PSC) was signed in 2008. Exploratory and appraisal drilling operations in Block 12 resulted in a natural gas discovery of considerable size ('Aphrodite' field: 125 bcm gross mean estimated resources). Five more Exploration Licenses were awarded during the 2ndHydrocarbon Licensing Round conducted in 2012, to Eni/Kogas for Blocks 2, 3 & 9 and to Total for Blocks 10 & 11.

Hydrocarbon exploration activities also took place by ENI (in Blocks 2, 3 and 9) and Total (in Blocks 10 and11). ENI also carried out 2 exploratory drillings during the period 2014-2015 in Block 9, but these did not result in any findings.

In February 2018, the ENI / Total joint venture completed the first exploratory well "Calypso 1" in Block 6, which resulted in a gas discovery. Moreover, in February 2019, the ExxonMobil/Qatar Petroleum consortium discovered a substantial gas reservoir in the Glaucus-1 well in Block 10. The consortium spudded an appraisal well in the block in late December, 2021.

Finally, hydrocarbon exploration activities in Cyprus's Exclusive Economic Zone are ongoing and a number of exploration wells are planned for the next two years, with the aim of discovering further hydrocarbon deposits. In December 2021, The Cypriot government awarded a license for natural gas exploration rights for the offshore block 5 to a consortium made up of ExxonMobil and Qatar Petroleum.

Map 5.17 **Offshore exploitation licenses in Cyprus's Economic Exclusive Zone (EEZ)**

(a) Natural Gas Supply and Demand (in bcm)

An LNG import terminal will be constructed in the Vasiliko Port, which is to be operated by the Cyprus Ports Authority. It will include a floating storage and regasification unit (FSRU) comprising a gas export system and loading arm equipped with meters, gas compressors, filters, heaters, and export arm pipelines. The FSRU will be permanently berthed in Vassilikos bay and have a storage capacity of 125.000m³. It will be capable of unloading LNG from LNG carriers ranging in size between 120.000m³ and 217.000m³. The Cyprus LNG market segment and potential gas consuming sectors include: Industrial users, power generation, domestic & commercial users, tourist facilities, road transport & the marine fuel/bunkering. Recent studies showed that the N. gas quantity to be delivered to the FSRU in LNG form is estimated at 0,8 bcm per annum, stating in 2022 doubling the amount by 2039. At present there is no gas infrastructure on the island such as a gas transmission and distribution grid. However, there are plans by DEFA (see next section) to establish such a grid over the coming years.

(b) Domestic Gas Market

The domestic gas market is regulated by the Cyprus Energy Regulatory Authority (CERA). All relevant EU Directives have been fully transposed and comprise the regulatory regime for the gas sector in Cyprus. The entities currently involved in the domestic gas market include: the Ministry of Energy, Commerce & Industry, the Cyprus Energy Regulatory Authority (CERA) and the Public Natural Gas Company (DEFA). Recently, the Natural Gas Infrastructure Company (ETYFA) was also established. DEFA is the authority responsible for the import, supply, wholesale transmission and distribution of natural gas in Cyprus.

(c) National N. Gas Policy -Strategic Plan

The introduction of natural gas to the local market in Cyprus is a main priority for the energy sector. The project, to introduce LNG through regasification unit (FSRU) is estimated at €290 million and €101-million has been secured through a grant from the EU under the Connecting Europe Facility (CEF) financial instrument, while the Cyprus Electricity Authority will contribute €43 million securing a 30% stake at ETYFA. Furthermore, ETYFA will cover the remaining part of the cost with funding from international lenders such as the European Investment Bank and the European Bank or Reconstruction and Development, with state guarantees. The infrastructure's operational expenditure (Opex) are estimated at €10,5m a year. Furthermore, DEFA has launched an additional tender for the supply of LNG supply, attracting expressions of interest from 25 suppliers, among the most dominant in the global LNG market. DEFA intends to import 0,6 bcm of LNG through a Gas Sale - Purchase Agreements (GSPAs) with duration between three to four years, maintaining the option to also purchase LNG from the spot market.

(d) Planned new projects

The EastMed pipeline (Project of Common Interest no. 7.3.1), is promoted by the IGI-Poseidon S.A. group and aims at connecting the European market with the gas resources of the Eastern Mediterranean region.

Map 5.18 **The EastMed pipeline**

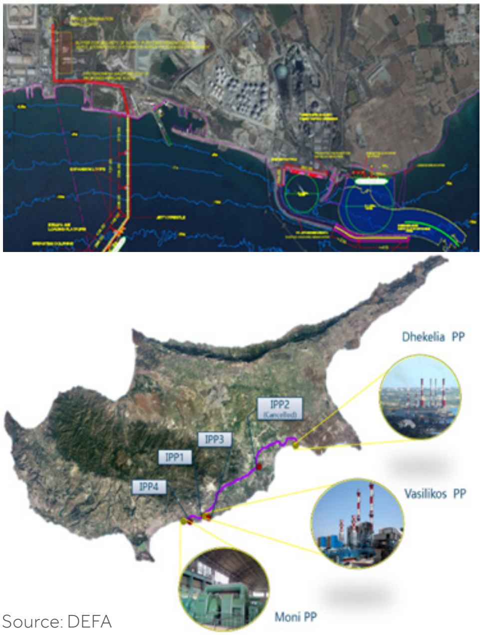
Source: https://gr.euronews.com

The EastMed pipeline will have an initial capacity of up to approximately 10 Bcm/year. In a second phase, the pipeline's capacity may expand up to 20 Bcm/y. It is an approximately 1900 km off-shore-pipeline divided into the five following sections: (1) offshore in the Levantine basin to Cyprus; (2) Cyprus-Crete; (3) Crete-Peloponnese; (4) Peloponnese-W. Greece; (5) W. Greece-Thesprotia. From there, at Florovouni, it will connect to the off-shore section of the Poseidon pipeline enabling the direct flow of gas to Italy and beyond in the European continent. Moreover, via the potential connection with the Greece-Bulgaria Interconnector, the EastMed pipeline can also allow the Levantine gas to reach the Balkan markets while the metering & regulating station at Megalopoli provides a connection to the Greek gas transmission system.

This Project of Common Interest (PCI) is also related to the energy security dimension, as it promotes diversification of energy sources and routes, ends the isolation of Cyprus and Crete, supports new gas production in the Eastern Mediterranean, including EU indigenous sources, and facilitates gas exchanges in South-Eastern Europe. It also contributes to the energy efficiency dimension, as natural gas is a more efficient fuel than the other fossil fuels and also help towards decarbonisation because natural gas has lower greenhouse gas emissions than those from conventional fuels.

CyprusGas2EU (Project of Common Interest no. 7.5 former 7.3.2) is being promoted by MECI and aims at introducing Natural Gas via LNG imports to the island of Cyprus in order to end the current energy isolation of Cyprus, by establishing the required infrastructure. Following the completion of a feasibility study in 2016, the Government of Cyprus (GoC) decided to proceed with a policy which will result in Liquified Natural Gas (LNG) imports in Cyprus, by approving the import of LNG. The LNG import route shall act as the single gas supply route until the indigenous gas sources become available for the Cyprus market, and will serve as an alternative supply route for ensuring the security of inland gas supply.

Map 5.19 **CyprusGas2EU project**



Source: DEFA

As per the above, a tender was announced by ETYFA (Natural Gas Infrastructure Company) in October 2018 for the LNG Import infrastructure in Vasilikos Bay), aiming for completion by early 2022. This infrastructure aims to end the energy isolation of Cyprus and has many cross-border impacts/ benefits for Cyprus and the Eastern Mediterranean region.

The tender entails the design, construction and operation of the project, which consists of (a) the procurement of a floating storage and regasification unit (FSRU), of at least 125,000 cubic meters storage capacity, to unload LNG from LNG carriers ranging in size from 120,000 cubic meters to 217,000 cubic meters (Q-Flex), (b) the Construction of offshore infrastructure for the permanent berthing of the FSRU, and (c) Onshore natural gas infrastructure and related construction components for gas delivery to the Vasilikos power station and potentially other gas consumers. On 13th of December 2019, a contract was awarded to the joint venture China Petroleum Pipeline Engineering, Metron, Hudong-Zhongua Shipbuilding and Wilhelmsen Ship Management.

The capital cost of the project is estimated to be €300 m, spread over three years (2020 - 2022). It is also expected that the project capital costs will be financed through a combination of a grant from the EU CEF (Connecting Europe Facility) of up to €101 m (project was approved by CEF in January 2018), debt financing (e.g. EIB, etc.) and an investment by the Electricity Authority of Cyprus (EAC) of €43m. The Operational and Maintenance cost is estimated to be around €200mn for a 20-year period.

The EuroAsia Interconnector is the official EU project developer of the 2.000MW electricity interconnector between Israel, Cyprus, Greece and Europe. The EuroAsia Interconnector is a leading European Project of Common Interest (PCI) labelled as an EU "electricity highway" connecting the national electricity grids of Israel, Cyprus and Greece through a 1.208 km subsea HVDC cable. It is expected that **EuroAsia** Interconnector construction will be completed by end of 2023. The statutory permit granting procedure for PCI "EuroAsia Interconnector" started in November 2019 and will be completed until the comprehensive decision is taken by NCA, by end of 2020. Immediately after the completion of the granting procedure, the construction phase will begin and expected to last for three years. Consequently, commercial operation will start by Q1 2024 where an interconnectivity level of 15% will be achieved.

Map 5.20 **Map of EuroAsia interconnector**

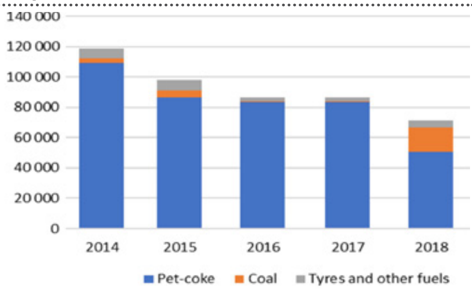
Source: https://euroasia-interconnector.com/

Solid Fuels

All solid fuels used in Cyprus are imported and include pet coke, coal and since 2005 a small quantity of used car tires that come from the domestic market. During the year 2018, the use of solid fuels (pet-coke, coal and tyres) was about 3,1% of the total primary consumption, while this share fell to nearly zero in 2013. The quantity of used tyres are disposed off locally. In 2018, 910.071 new tires were imported.

The imports of solid fuels in Cyprus aim exclusively at meeting the energy needs of the domestic cement industry.

Figure 5.83 **Primary consumption of Solid Fuels in the period 2014-2018**



Source: National Energy & Climate Action Plan 2020-2030

Electricity

(a) Electricity Market

For more than 50 years, the electricity market in Cyprus had been operating as a monopoly under a vertically integrated company, the Electricity Authority of Cyprus (EAC). Since its establishment in 1952, EAC has been the only responsible entity for the generation, transmission, distribution and supply of the electricity to the final customers. In 2003 and as a first step to achieve the transition into a liberalised electricity market, the Transmission System Operator Cyprus (TSO Cyprus) and the Cyprus Energy Regulatory Authority (CERA) were established in accordance with the relevant European Union Directives. The Ministry of Energy, Commerce & Industry (MECI) is responsible for the overall policy, strategy and for transposing EU Directives into national legislation.

The main functions and responsibilities of the TSO Cyprus include the operation of the electricity transmission system and the management of the electricity market in an objective and non-discriminatory basis and in a competitive environment. At the same time, the TSO should support and promote electricity generation from renewable energy sources. The responsibilities of the CERA include overseeing and regulating the market for electricity and gas, ensuring effective and fair competition, protecting the interest of consumers, ensure safety, quality, competence, and encourage the use of renewable energy sources for electricity production.

On 1st January 2004, the electricity market was liberalised by 35%. Five years later, on 1st January 2009, the electricity market was further liberalised for all "non-domestic" consumers, thus bringing the total market liberalisation to 65%. Despite the fact that the electricity market was liberalised 'on paper', actual liberalisation still lacks behind significantly, and in fact never happened. A number of issues have prevented the smooth transition and operation of a competitive electricity market in Cyprus, and are summarized as follows: (a) The vertically integrated EAC (which had a monopoly on the production and sale of power since 1952) and its Public Corporate status, (b) the lack of national experience regarding the functioning of liberalized electricity markets, (c) the small size of the electricity market itself, and (d) the newly established institutional structures (e.g. CERA, TSO).

(b) Electricity Transmission

Regarding the electricity transmission, the voltage commonly used at national level for the overhead lines is 132kV. Only two overhead lines are designed for 220kV (circuit length is 90.8km) but these operate at the commonly used voltage of 132kV. There are also some overhead lines designed for 132kV but operated at 66kV, in addition to the overhead lines operating at 66kV. Apart from these, underground cables exist mainly operating at 132kV and very few at 66kV. The Transmission System is complemented with a great number of substations.

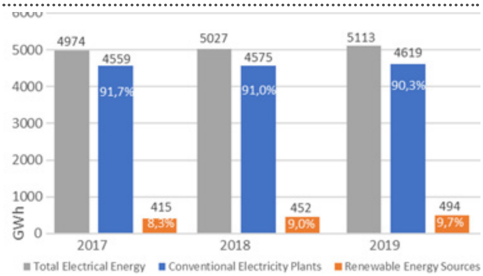
(a) Electricity Supply and Demand

Electricity in Cyprus is generated by:

- Three power stations operated by the Electricity Authority of Cyprus (EAC) - Conventional Power Plants
- Independent producers using Renewable Energy Sources (RES).

In 2019 the total electricity generation in Cyprus was around 5.113 GWh, with most of it (90,3%) generated by the three conventional power plants of EAC[12]. Electricity generation witnessed gradual growth over the last three years due to increased demand.

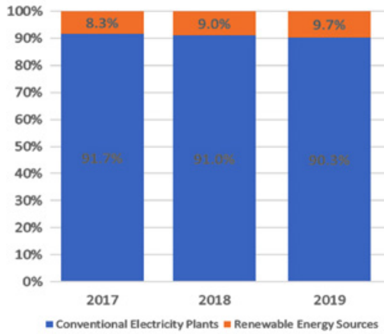
Figure 5.84 **Electricity Generation for the period 2017-2019**



Source: TSO Cyprus

The proportion of electrical energy from conventional power plants has been decreasing over the last three years since there is increasing penetration of renewable energy systems (mainly PV systems). More specifically, the proportion of electrical energy from conventional power plants decreased from 91,7% in 2017 to 90,3% in 2019, while the percentage of electrical energy generated by RES increased accordingly. As of 2017, the electrical energy generated by renewable energy sources accounted for 415 GWh, corresponding to 8,3% of the total electrical energy generated in Cyprus. In 2019, the corresponding electrical energy accounted for 494 GWh that represents 9,7% of the total electricity generation in Cyprus.

Figure 5.85 **Share of electricity generation for the period 2017-2019**



Source: TSO Cyprus

(b) Installed Capacity of conventional electricity plants

Cyprus power generation system consists of three thermal power stations with a total installed capacity of 1.478MW, as analysed in Table 5.102:

Table 5.102 **Installed Capacity of the three thermal power stations**

Vasilikos Power Station	
Unit Capacity	Total Power
3 x 130 MW Steam Units	390 MW
1 x 38 MW Gas Turbine	38 MW
2 x 220 MW Combine Cycle Units	440 MW
Dhekelia PowerStation	
Unit Capacity	Total Power
6 x 60 MW Steam Units	360 MW
2 x 50 MW Internal Combustion Engines	100 MW
Moni PowerStation	
Unit Capacity	Total Power
4 x 37,5 MW Gas Turbines	150 MW
Total Installed Capacity	**1.478 MW**

Source: EAC

Vassiliko Cement Works has 11 MW of internal combustion engines, which are capable of burning heavy fuel oil or gasoil and could (probably) be modified to burn natural gas[13].

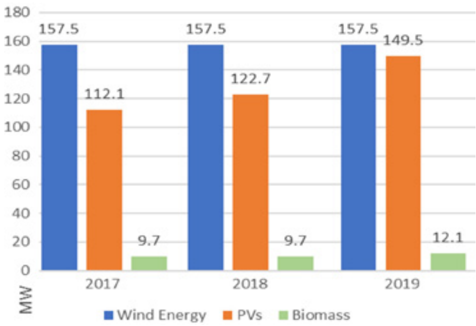
[12] Obtained from TSO Cyprus
[13] Obtained from the report "Master plan of the Vasilikos area" (October 2013)

The steam units at Vasilikos are used for base load generation, while the steam units of Dhekelia are used for intermediate load generation. The gas turbines are mainly used during system peak loading. All stations use heavy fuel oil for the steam turbine units and gasoil for the gas turbine units. The combined cycle units use gasoil as fuel until the arrival of natural gas in Cyprus [14].

(c) Installed Capacity of Renewable Energy Systems

RES applications for electricity generation include wind energy systems, PV systems and biomass systems. No hydroelectric plants or nuclear plants currently exist in Cyprus and none are planned either. The total installed capacity of RES in Cyprus increased from 279,3MW in 2017 to 319,1MW in 2019, corresponding to 14,3% increase. During this 3-year period, PV installations had a rapid growth, biomass systems had a slight increase, while wind energy systems remained at the same level. The share of each system in the total RES capacity is illustrated in Figure 5.86.

Figure 5.86 **RES installed capacity by system for the period 2017-2019**



Source: TSO Cyprus

(d) Planned New Capacity - Investments

The import of natural gas will initiate the gradual conversion of the oil-fired power stations, in order to run on natural gas fuel and will also encourage the establishment of independent power producers. Already, the combined cycle units and the 3 steam turbines at Vasilikos power station that currently use gasoil and heavy fuel oil, respectively, have the capability to run on natural gas. So far, there are 4 licensed independent power producers (1 x 260MW, 1 x 230MW, 1 x 105MW, 1 x 17,5MW)[15] with none of these being implemented yet. EAC was also licenced for the construction of an 160MW power station in Vasilikos area.

In an attempt to stimulate the penetration of RES-e and get closer to the 2020 national binding target, the government of Cyprus introduced two support schemes during the last years, targeting large RES-e producers (>1MW). In the first Support Scheme, projects of 116,3MW total capacity (102MW PV systems, 12MW wind energy systems, and 2,3MW biomass systems) were licensed, while in the second Support Scheme the capacity of the projects that proceeded to the final licensing was 260MW, all PV systems. So far (April 2020), 40 RES projects (36,5 MW total capacity) under the 1st scheme have been implemented. The rest projects under this scheme, as well as the projects under the second Support Scheme are due to be implemented within the following months.

(e) Electricity Imports - Exports

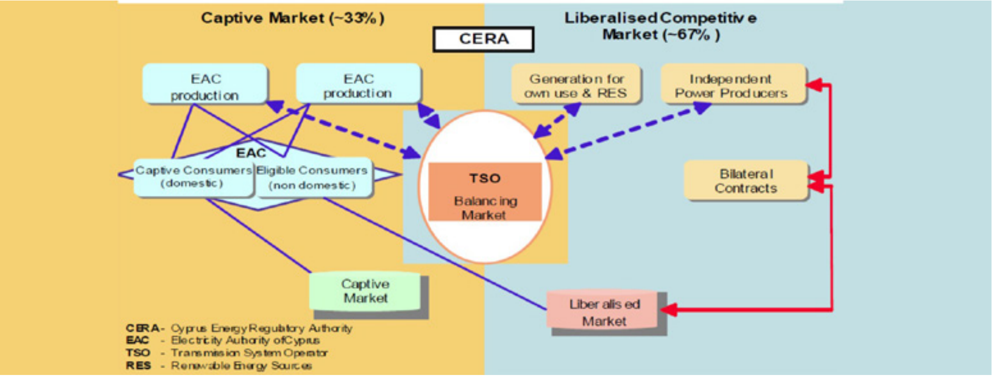
No electricity imports/exports currently exist due to the lack of interconnections between Cyprus and other countries.

(f) Tariffs

The domestic electricity market is regulated by the Cyprus Energy Regulatory Authority (CERA) under the relevant provisions of the Electricity Directive of the 3rd Energy Package, which have been fully transposed and dictate the regulatory regime for the electricity sector in Cyprus. The entities currently involved with the domestic electricity market are the Ministry of Energy, Commerce and Industry (MECI), the Cyprus Energy Regulatory Authority (CERA), the Electricity Authority of Cyprus (EAC), the Transmission System Operator (TSO) and the independent electricity producers and suppliers.

13 OObtained from EAC (https://www.eac.com.cy/EN/EAC/Sustainability/Pages/ElectricityProduction.aspx)
14 Obtained from CERA (https://www.cera.org.cy/el-gr/ilektrismos/details/katalogos-adeiwn)

Figure 5.87 **RES installed capacity by system for the period 2017-2019**



Source: EAC

However, this is about to change when the market gets fully liberalized and the new electricity market rules come into force. The full liberalization of the electricity market of Cyprus is projected to be in October 2021. Until then, market players can take part in the **transitional electricity market model** that has been in operation since the 1st of September 2017. In this transitional model, the electricity market participants, which can be licenced producers (from RES or conventional fuels) or licenced suppliers (until today 13 independent suppliers obtained licenses), conclude bilateral agreements (Power Purchase Agreements - PPA) amongst each other with the objective of selling/buying the generated electrical energy.

A licenced independent supplier will have the right to participate in the transitional electricity market model only once they agree bilateral contracts with customers (Power Supply Contracts - PSC) of at least 10MW total capacity. A licenced independent producer can participate in the transitional electricity market model only if their RES or conventional power station has a nominal power of at least 500kW.

Cyprus's electricity sector relies primarily on oil imports, while the electricity system in Cyprus is isolated (no interconnections with other countries exist yet). This makes the price of electricity exceptionally vulnerable to fluctuations in international oil prices. On the 1st of September 2017, CERA set a new tariff methodology that will be in force for at least 5 years from the date of implementation or until the full liberalization of electricity market. According to the new methodology, the number of tariffs decreased from 30 to 11. The amount (price) of the tariffs is revised and approved by CERA every year. The tariffs for industrial consumers (tariffs with codes 30, 40 and 50) have 8 different charging periods according to the month, the day and the time of the day (peak/off-peak) as shown on the following table:

Table 5.103 **Breakdown of energy charge periods**

Periods	October - May		June - September	
	Weekdays	Weekends & Holidays	Weekdays	Weekends & Holidays
Peak	16:00 - 23:00	16:00 - 23:00	09:00 - 23:00	09:00 - 23:00
Off-Peak	23:00 - 16:00	23:00 - 16:00	23:00 - 09:00	23:00 - 09:00

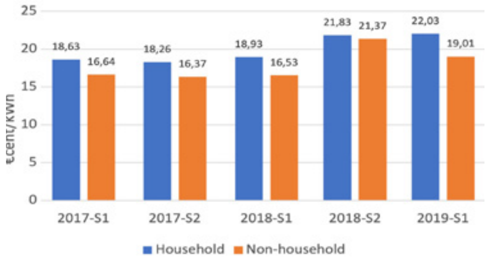
The average electricity price for household and non-household consumers in Cyprus for the first half of 2017 until the first half of 2019 are presented in Figure 5.88. Note that the prices include taxes, levies and VAT[16].

[16] Obtained from Eurostat (https://ec.europa.eu/eurostat/web/energy/data/database)

Figure 5.88 **Average electricity price for household and non-household units for the period 2017-2019**



Source: Eurostat

The electricity prices in Cyprus are among the highest in Europe and this is mainly attributed to the extensive reliance on oil-fired electricity generation, which continues to supply around 90% of the electricity demand. The increasing penetration of renewable energy sources, the forthcoming introduction of natural gas in the electricity production and the full liberalization of the electricity market are among the factors that can contribute to the reduction of the electricity prices, at least in long term.

The full liberalization of the electricity market that is projected to take place in October 2021 aims to:

- Create a competitive energy market that will offer security of electricity supply at competitive rates.
- Enhance the freedom of customers to make an effective choice of supplier.
- Continue to promote measures for the protection of vulnerable consumers.
- Allow RES power generation to enter the competitive electricity market.
- Enhance competition in the electricity generation business sector.

(f) Cross-Border Interconnections

The power system of Cyprus is completely isolated, as there are currently no interconnections to the electricity grids of neighbouring countries. However, a new project, involving cross-border interconnections, is planned and once this materializes it is expected to lift the current energy isolation of Cyprus, allowing electricity imports/exports.

(g) Planned New Projects

EuroAsia Interconnector Project

The integration of Cyprus energy system into the regional markets is pursued through the promotion of the EuroAsia Interconnector Project, which is a leading European Project of Common Interest (PCI) labelled as an EU "electricity highway" connecting the national electricity grids of Israel, Cyprus and Greece through a 1.208km subsea HVDC cable. This subsea electricity cable will carry up to 2.000MW of electrical energy produced, mainly from natural gas in power stations located in Cyprus and Israel, as well as from renewable energy sources. It will also allow for the reverse flow of electricity, thus enhancing the security of supply and lifting the energy isolation of Cyprus, adding at the same time stability to its electricity system.

The development and realisation of EuroAsia Interconnector constitute a very complex process. The implementation dates as provided to the European Commission, for the commencement of Stage 1 are as follows:

- Cyprus - Greece commissioning in December 2023
- Cyprus - Israel commissioning in December 2023

Map 5.21 **EuroAsia Interconnector Project**

Eastern Mediterranean (EastMed) Pipeline[18]

EastMed is a 1.900km natural gas pipeline project that is intended to connect the gas reserves of the eastern Mediterranean with Greece.

The project is currently designed to transport initially 10 Bcm/y (billion cubic meters of gas per year) from the off-shore gas reserves in the Levantine Basin (Cyprus and Israel) into Greece and, in conjunction with the Poseidon and IGB pipelines, into Italy and other South East European countries. Furthermore, the pipeline would allow to feed Cyprus internal consumption with additional 1 Bcm/y.

The EastMed project current design envisages a 1.300 km offshore pipeline and a 600 km onshore pipeline. The pipeline, starts from the new natural gas discoveries in the East Mediterranean region and comprises the following sections:

- 200 km offshore pipeline stretching from Eastern Mediterranean sources to Cyprus;
- 700 km offshore pipeline connecting Cyprus to Crete Island;
- 400 km offshore pipeline from Crete to mainland Greece (Peloponnese);
- 600 km onshore pipeline crossing Peloponnese and West Greece.

The EastMed pipeline is preliminarily designed to have exit points in Cyprus, Crete, mainland Greece as well as the connection point with the Poseidon pipeline.

The project has been confirmed as a Project of Common Interest (PCI) by the European government. It is being developed by IGI Poseidon, a 50:50 joint venture between Public Gas Corporation of Greece (DEPA) and Edison International Holding.

The energy ministers of Greece, Israel, and Cyprus signed the final intergovernmental agreement for the pipeline project in Athens on January 21 2020.

The project has been confirmed as a Project of Common Interest (PCI) by the European government. It is being developed by IGI Poseidon, a 50:50 joint venture between Public Gas Corporation of Greece (DEPA) and Edison International Holding.

Cyprus LNG import terminal

The FSRU-based LNG import project at Vasilikos Bay in Cyprus is meant to lessen the dependence of the island on heavy fuel oil and petroleum products for power generation. The project will initially supply gas to the Vassilikos Power Station (VPS) and later to the Moni and Dhekelia power stations and independent power producers.

The LNG import terminal will be constructed along the Vasiliko Port in Cyprus, which is operated by the Cyprus Ports Authority. It will include a floating storage and regasification unit (FSRU) comprising a gas export system and loading arm equipped with meters, gas compressors, filters, heaters, and export arm pipelines.

A multinational consortium led by the state-owned China Petroleum Pipeline Engineering has been awarded a contract for the construction of the LNG import terminal. Other consortium members are Metron Energy Applications, CPP, Hudong-Zhonghua

Shipbuilding and Wilhelmsen Ship Management. Under the contract, valued at €500M ($571.7M), the consortium will procure an FSRU of at least 125 000 m3 storage capacity and will also supply gas over 20 year period. It will be capable of unloading LNG from LNG carriers ranging in size between 120,000m³ and 217,000m³. The project is co-financed by the EU through the EU's Connecting Europe Facility (CEF)[19].

RES Projects

With regard to the renewable energy sector, 145 PV projects of 260MW total capacity that were licensed under the 2nd Support Scheme for large RES-e projects, are due to be implemented in 2020-2021. Also, 37 projects (79,6 MW total capacity) out of 77 projects under the 1st Support Scheme that have not been implemented yet, are due to be completed during 2020 (Source: MECI).

Other small PV projects under the ongoing support schemes for net-metering systems (for residential and non-residential buildings) are expected to be implemented within 2020, contributing to the increase of RES share in the electricity generation mix of Cyprus. Until the end of 2019 and since 2013 when the scheme was initiated, 14.779 systems of around 54MW total capacity were implemented (Source: EAC). Also, some medium-size PV systems are about to be installed under the net-billing support scheme. Until the end of 2019 and since March of 2019 when the scheme was initiated, 72 PV systems of 4,3MW total capacity and 1 Biomass system of 2,4MW capacity were installed (Source: EAC).

By the Regulatory Decision 02/2018 (Act 259/2018) CERA invited the DSO to proceed with the appropriate actions to initiate the required procedures for the complete and massive installation of smart metering systems. The aim is to install 400.000 smart meters by 2027[20] based on the following timeline:

Table 5.104 **Timeline of smart meters installation**

Phases	Deadline	Smart meters installation
1st	January 2021	57.143
2nd	January 2022	57.143
3rd	January 2023	57.143
4th	January 2024	57.143
5th	January 2025	57.143
6th	January 2026	57.143
7th	January 2027	57.143

Source: CERA

Renewables

Cyprus has a great potential regarding Renewable Energy Sources (RES), which include solar and wind energy, biomass and the use of low enthalpy geothermal energy. All RES plants/systems in Cyprus are either: (1) autonomous systems (not connected to the electricity grid), or (2) producers of electricity from RES that are connected to the grid and feed their electricity into it, or (3) producers of electricity from RES

[19] Obtained from Europa.eu (https://ec.europa.eu/inea/sites/inea/files/cefpub/cef_implementation_brochure_2019.pdf)
[20] Obtained from CERA (https://www.cera.org.cy/Templates/00001/data/ektheseis/2018_en.pdf)

that are connected to the grid and use the electricity produced for their own use and feed the excess electricity into the grid (PV systems under net-metering scheme & PV or biomass systems under net-billing scheme) (4) Solar thermal systems for domestic hot water use.

(a) Overview of Sector's Development[21]

Despite the increasing contribution of renewable energy sources in the gross final energy during the last years, there is still plenty of room for further exploitation considering the country's real potential. During the period 2016-2018 the increase in the contribution of RES in the gross final energy consumption of the country increased from 9,27% to 13,78% (based on preliminary results). As an EU Member State, Cyprus must comply with a national renewable energy target currently set at 13% of gross final energy consumption from renewable energy by the end of 2020 and 23% by 2030.

During the period 2016-2018, the primary energy supply of RES had a significant increase of 47%, reaching 238,3 ktoe in 2018. Approximately 72 ktoe (51.8%) came from the production of hot water from solar thermal systems, 46 ktoe (19%) from the use of heat pumps, 28 ktoe (12%) from the use of renewable municipal waste, 17 ktoe (7%) from the use of photovoltaic systems and 13,2 ktoe (6%) from the use of biogas for electricity generation, 9 ktoe (3%) from the use of biofuels in transportation, 19 ktoe (8%) from the use of wind farms and 1,6 ktoe (1%) from geothermal energy systems.

Cyprus along with Israel were the first countries in the Mediterranean–European area back in the 1950's to start using solar energy for domestic water heating. Hence the citizens of Cyprus are familiarized with the use and utilisation of solar thermal technology for the production of hot water, since 92% of the households and over 50% of the hotels in Cyprus use solar water heating systems to cover the majority of their hot water needs.

According to an EU survey, the extensive use of solar thermal technology makes Cyprus one of the world's leading countries in thermal solar energy applications for residential uses, with nearly 1m² installed solar collector area per capita. Despite the extremely widespread proliferation of solar thermal systems for domestic hot water uses, the solar heat applications for Industrial processes in Cyprus are still limited.

(b) Incentives/Support Schemes for RES

The government of Cyprus has developed various support schemes and incentives for the promotion of RES and energy efficiency (EE) projects. The majority of these instruments are intended to be financed by the national budget, some with assistance from EU funds. The national support schemes that use the available funds from the Special Fund for RES & EE can be divided into 3 main categories: Support Schemes for RES, Grant Schemes for RES, and Grant Schemes for Energy Efficiency.

Most of the Support Schemes for RES are related to **Net Metering** and **Net Billing** and target residential, tertiary & industrial sectors. The Net Metering support scheme is open to household owners and SMEs from all sectors of economic activity. The size of the PV system should not exceed 10 kW. The Net Billing scheme is open to all enterprises from all the sectors of the economy. The size of the PV or biomass systems should be between 10kW up to 10 MW.

The Grant Scheme for RES targets the residential sector. Grants are available for the installation of domestic PV systems under the Net-metering scheme and replacement of domestic solar water heaters. In an attempt to further stimulate the penetration of RES-e and get closer to the national binding 2020 target, the Cyprus government introduced two Support Schemes during 2018-2019 targeting large RES-e producers.

21 Obtained from EUROSTAT (2020) and MECI

In the **first Support Scheme (phase I)** a total capacity of 120MW was offered to interested and potential investors. The scheme was open between October 2017 and April 2018 for project applications. During this period, the total capacity of the applications reached 395,3MW, mainly for PV systems. More specifically, the applications for PV systems, wind energy systems and biomass systems were 376,5MW, 16,5MW and 2,3MW respectively. The decision was to proceed to the final licencing of 101MW PV systems, 16,5MW wind energy systems, and 2,3MW biomass systems as these projects have been proven mature (Source: Ministry of Energy, Commerce and Industry).

The second Support Scheme (phase II) was ongoing between April 2019 and June 2019 with the available offered capacity to potential investors being at 150MW, regardless of the RES technology (i.e. several RES-e projects with capacity up to 150 MW in total could be licensed). Until the end of the scheme, applications for a total capacity of 350MW have been made. The MECI announced on the 16th August 2019 that the number of applications that have been approved exceeded the 150 MW, and thus an additional capacity of 110 MW was offered by MECI to cover the eligible applications, namely up to 260 MW. Eventually 260MW of PV systems were accepted (Ministry of Energy, Commerce and Industry).

A grant scheme for installation of car charging points (for electric or hybrid cars) and smart meters in homes has been already agreed by the Council of Ministers in November 2019 and is about to be announced and initiated during the following weeks (June 2020).

The support of investments for the exploitation of RES, the simplification of the licensing procedures and the establishment of a stable, transparent and safe investment environment regarding RES has been one of the basic priorities in Cyprus. In addition, according to the relevant EU Renewable Energy Directive, all new renewable energy sources installations have grid connection priority rights.

Cyprus continues to promote renewable energy investments and implement measures aimed at increasing the level of penetration of renewable energy sources into the power generation system. The new electricity market model takes into account a structured approach for the increase of electricity generation from Renewable Energy Sources and allows power generation from RES to enter the competitive electricity market.

According to the EU Directive 2009/28/EC, concerning the promotion of the use of energy from Renewable Energy Sources (RES), the share of energy from RES in all forms of transport by 2020 must be at least 10% of the final consumption of energy in transport (Cyprus has been granted a derogation from the inclusion of jet fuel in the calculation of the final consumption for all forms of transport). This obligation is met at a great degree by the blending of biofuels in conventional fuels.

(c)Installed Capacity per Source (in MW)[22]

At the end of 2019, the total installed capacity per RES-e was as follows:

• PV systems	149,5 MW
• Wind Energy systems	157,5 MW
• Biomass systems	10.4 MW

(d) Planned New Major Projects

Currently the planned projects include:

- 260MW RES projects that were licensed under the second Support Scheme for large RES-e projects.
- 79,6MW RES projects that were licensed under the first Support Scheme for large RES-e projects.
- 50 MW Concentrated Solar Power (CSP). The projected is to include 300 solar thermal receivers and hundreds of sun-tracking mirrors north of Limassol in Cyprus.
- Small-size PV projects under the ongoing support schemes for net-metering systems.
- Medium-size PV and biomass projects under the ongoing support schemes for net-billing systems.

Energy Efficiency and Cogeneration

Building sector [23]

Following the accession of Cyprus to the EU in 2004, specific measures and policies have been implemented towards improving the energy efficiency of buildings. As of late 2007, mandatory measures were implemented for energy saving through the insulation of the building envelope, for all new buildings and all existing buildings over 1.000 square meters which underwent major renovations. As of 1 January 2010, an additional minimum energy performance requirement was added to the effect that all new buildings should be classified as a minimum under energy class B in the Energy Performance Certificate (EPC).

This has led to the implementation of better thermal insulation. Moreover, the installation of a solar thermal systems for the production of hot water was made mandatory for all new dwellings, and the fitting of a standby installation for the use of renewable power systems was made mandatory for all new buildings. By the Decree of 2013, the maximum U-values of the building envelope were reduced by approximately 15%, while a maximum shade coefficient for windows was adopted for the first time. The Decree states that, in respect of buildings that are not used as residences, at least 3% of total energy consumption must originate from renewable energy sources. As of 1 January 2017, the U-values for the building envelope were further reduced aiming to have the cost-benefit ratio over the lifecycle of the building reach its cost-optimal level, i.e. close to the NZEB requirements, as laid down in RAA 366/2014.

The minimum percentage of total energy consumption that must originate from renewable sources was also increased significantly both for residential and non-residential buildings. Recently new minimum energy efficiency requirements were announced by the Ministry of Energy that will come into force from 1 July 2020. These will require all residential buildings undergoing major renovation to be energy class A, while all non-residential buildings energy class B+. There will be also specific requirements for hotels.

Industrial sector

In general, Cyprus' energy system has experienced a steady drop in final energy intensity in recent years. Regarding the industrial sector, the energy intensity is rather low as compared to the corresponding values of other EU Member States, due to the nature of the local industrial sector. However, energy efficiency in the industrial sector has improved significantly, as the branch of industry that is subject to the greenhouse gas emissions trading scheme (which consumes approximately 50% of the total final energy consumed by the industrial sector) has now implemented energy-saving measures and uses combined heat and power technology. Nevertheless, there is still a tremendous potential for investments for energy efficiency measures in the industrial sector, since there is an urgent need for individual measures for improvement of their industrial processes equipment.

It is worth mentioning that the industrial sector showed gradual growth over the last decade. In fact, in 2018 the final electricity consumption of the sector was 884 GWh, an increase of 12% from 2009. Although, between 2012 and 2016 the sector has experienced a significant decline due to the economic recession, it is now showing significant signs of recovery. Even the two strongest economic activities of the industrial sector (construction and cement) declined significantly that period (2012-2016) due to the decrease in demand for construction of new buildings[24].

According to data from the Electricity Authority of Cyprus (EAC) for 2017, manufacturing activity contributes 64% of total electricity

[23] Obtained from the report "4th National Energy Efficiency Action Plan of Cyprus" (September 2017)
[24] Obtained from the report "Market Assessment Report for Renewable Energy and Energy Efficiency Small Investments in Cyprus" (October 2019)

consumption in the industrial sector; while the water collection, treatment and supply activity contributes 35%. Out of the total electricity consumption of the manufacturing activity, 30% refers to the manufacture of food products and 39% to the manufacturing of other non-metallic mineral products (e.g. cement, glass and gypsum industry). Other important economic activities are plastics products manufacturing, pharmaceuticals, and the beverage industry in terms of energy consumption.

Residential sector

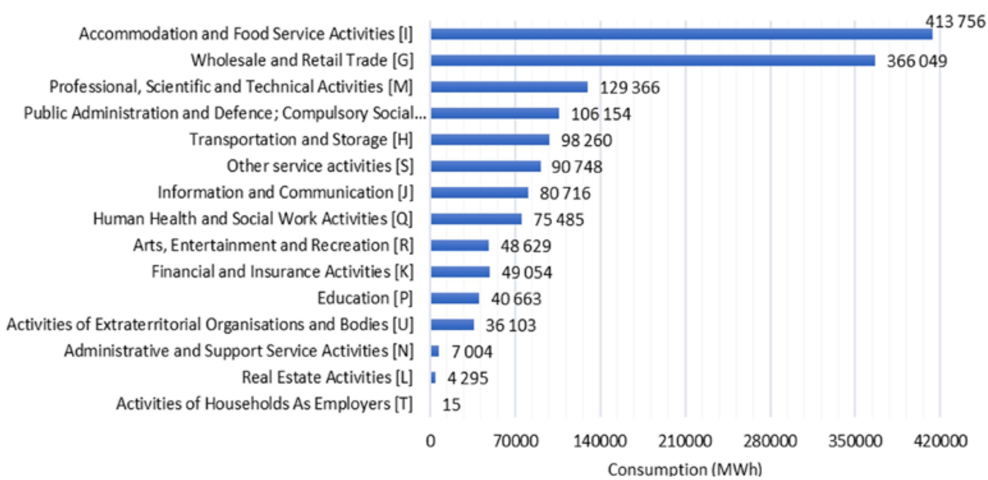
Regarding the residential sector in Cyprus, the energy intensity is lower than the European average level, due to the country's moderate climate; however, it is tending to rise as the population's revenues are increasing and the standard of living improves. There is no doubt, that the residential sector is expected to play a key role in meeting the national energy efficiency targets for 2020 but also for 2030. In Cyprus, 91% of all buildings were built before the introduction of mandatory energy performance requirements, and 50% of them do not have any type of thermal insulation.

The potential for energy efficiency is obvious even from previous support schemes, such as 'save and upgrade', which provided more than € 10 million of public funding for EE in the housing sector. Due to the exhaustion of its funds, this scheme was closed nine months before the predetermined closing date of the scheme. This shows the tremendous interest from house-owners. The scheme funded 50% - 75% of the total investment costs, which means that € 20 million were absorbed by the market in less than a year [25].

Tertiary sector

Similarly, as with the case of the industrial sector, the tertiary sector showed gradual growth over the last decades. The final electricity consumption of the tertiary sector in 2018 was 1.816 GWh, which presents an increase of 61% compared to 1999 levels. As depicted in Figure 5.89, in 2017 'Accommodation and Food Services' appears to be the economic activity with the highest electricity consumption (414 GWh); followed by 'Wholesale and Retail Trade' (366 GWh); the 'Professional, Scientific and Technical Activities' (129 GWh); and 'Public Administration and Defence - Compulsory Social Security' (107 GWh).

Figure 5.89 **Electricity consumption in the tertiary sector in 2017**



Source: CYSTAT, 2017

[25] Obtained from the report "Market Assessment Report for Renewable Energy and Energy Efficiency Small Investments in Cyprus" (October 2019)

It is important to note that the electricity consumptions mentioned in Figure 5.89 refer to aggregate amounts per sector. In order to identify the most energy intensive SMEs in Tertiary sector, the most appropriate performance indicators should be used. As Table 5.105 shows, the ranking of the most energy intense SMEs sectors is as follows: Private hospitals and clinics, private offices, Private schools and hotels.

Table 5.105 **Most energy intense SMEs in the Tertiary sector**[26]

	Tertiary Sector		
SME sectors	**performance Indicator**	**Measurement unit**	**Quantification**
Private Hospitals and clinics	Energy intensity per company - kWhfinal/unit	Energy intensity per company - kWhfinal/unit	3.371
Private office buildings	Energy intensity per company - kWhfinal/unit	kWh/ employee	2.354
Private schools	Energy intensity per company - kWhfinal/unit	kWh/student	306
Hotels and other touristic accommodation	Energy intensity per company - kWhfinal/unit	kWh/guest	44
Retail shops	Energy intensity per company - kWhfinal/unit	kWh/client	6
Restaurants	Energy intensity per company - kWhfinal/unit	kWh/client	3
Airports	Energy intensity per company - kWhfinal/unit	kWh/passenger	3
Sport facilities	Energy intensity per company - kWhfinal/unit	kWh/guest	2,5
Bakeries	Energy intensity per company - kWhfinal/unit	kWh/ client	2
Supermarkets	Energy intensity per company - kWhfinal/unit	kWh/client	2
Coffee shops	Energy intensity per company - kWhfinal/unit	kWh/client	1

Source: Cyprus Employers & Industrialists Federation (OEB)

Concerning the residential buildings, the majority of buildings in the tertiary sector has been constructed without requirements for thermal insulation or any other energy efficiency measures. In fact, the majority (83%) of the building stock of the tertiary sector was built before the first legislation regarding energy performance requirements. In general, it can be assumed that the tertiary sector follows the description of the structure and construction materials of the residential sector, as well as the same period of development. Therefore, there is a huge potential of energy efficiency improvement in the tertiary sector. This potential is particularly high in hotels and for that reason strict minimum energy performance requirements were set from 1 July 2020.

Public buildings

In Cyprus, public buildings are used by central government authorities (Ministries, police, the Attorney General's Office); local authorities; public schools, public universities and other public educational institutions; and the army.

In most public buildings, electricity is used to meet all energy needs, hence implying an average consumption of 130 kWh / m2 per year. In general, almost all public buildings in Cyprus are of low energy efficiency, i.e. their Energy Performance Certificates (EPC) show buildings with energy class C to H. It should be noted that, according to the national legislation all public buildings with a total useful floor area over 250 m2 must have an EPC issued. In addition, according to Article 5 of the Energy Efficiency Directive, there is an obligation to save energy on buildings used by central government authorities at 3,316 GWh per year for the period 2014-2020. According to the MECI, there are 175 buildings (useful floor area over 250 m2) which are owned and used by central government authorities, with a total floor area of 584.202 m2. This number of buildings do not meet the national minimum energy performance requirements. It should be also noted that this number of buildings do not include those except from the minimum energy performance requirements and the requirement to issue an EPC as well as buildings belonging to the armed forces or buildings serving national defence purposes. The Department of Public Works of the Ministry of Transport, Communication and Works, is responsible for the condition and upgrade of the buildings of the central government[27]. Table 5.106 provides an overview of the public buildings with information on their total floor area, number of establishments, average floor area and final electricity consumption per square meter.

Table 5.106 **Timeline of smart meters installation**

	Total floor area (m^2)	Number of establishments	Average floor area (m^2)	Electricity consumption (kWh/m^2 per year)
Tertiary	222.404	N/A	N/A	304
Public	1.886.370	1.087	1.735	75
Secondary	613.546	144	4.261	71
Primary	453.755	325	1.396	65

Source MECI, 2017

Transport sector

The energy intensity in the transport sector of Cyprus is among the highest in the EU, mainly due to the large percentage of road transport operations. However, there has been a remarkable improvement in this sector in recent years. The increase in the energy efficiency of private vehicles and the import of smaller and more efficient cars have led to better results, although public and mass transport in Cyprus are not adequately developed.

Cyprus has the highest car ownership rate in the world with 742 cars per 1.000 people. Other means of transport are very low compared to other countries. According to the Ministry of Transport, 91% of the transportation of Cyprus citizens comes from the use of their own-vehicles, 6% from the use of bicycles or walking and 3% from the use of public transport. In addition, petrol vehicles account for 87% of the total share of vehicles, followed by diesel vehicles with 12% and hybrid and electric vehicles at only 1%.

Cyprus is ranked 24th out of the 28 EU member states for renewable energy use in transport, according to a Eurostat study based on 2017 data (EUROSTAT, 2018). In 2017, the share of energy from renewable sources used for transport in Cyprus stood at 2,6%, compared to the EU average of 7,6%.

The current penetration of alternative fuels in Cyprus is quite low. The amount of biodiesel blend is low as well as the number of electric vehicles on the road. Correspondingly, there is a limited amount of charging points present on the island. LPG vehicles are already in use, but LPG refuelling stations are not yet available. The maritime sector relies entirely on heavy fuel oil and medium distillates[28]. According to current Regulation (R.A.A. 11/2020), the percentage of biofuels that the suppliers of transport fuels (petrol and diesel) are obliged to blend with conventional transport fuel is 7,3%.

According to NECP, more than 1,3 billion Euro of investment is needed for the transport sector until 2030, including investments in infrastructure, changing fleets, etc. Thus, the increase of energy efficiency in the transport sector is considered to be of crucial importance.

(a) National energy efficiency Targets[29]

In the NECP, Cyprus set its indicative contribution to the EU 2030 energy efficiency target as:

27 Information obtained from the MCIT (2017)
28 Obtained from the report "Penetration of alternative fuels in Cyprus road and maritime sectors" (2019)
29 Information obtained from the Cyprus NECP (2020)

5

- Final Energy Consumption of 2,0 Mtoe in 2030, representing 13% reduction in final energy consumption*
- Primary Energy Consumption of 2,4 Mtoe in 2030, representing 17% reduction in primary energy consumption*
- Achieving cumulative energy saving of 243,04 ktoe during 2021-2030

* compared to the respective projection for Cyprus in the 2007 in the EU PRIMES 2007 Reference Scenario

Compared to the EU-wide target of 1.273 Mtoe of primary energy consumption in year 2030, Cyprus is expected to account for 0.21% to the EU wide target for primary energy consumption in 2030, which is higher than its current annual contribution of the EU primary energy consumption.

According to Article 5 of Directive 2012/27/EU that Member States should either renovate annually 3% of the total area of buildings owned and used by central government authorities or choose an alternative approach including other cost-effective energy-saving measures in selected privately-owned public buildings (including, but not limited to, deep renovations and measures to change the behaviour of users), in order to achieve by 2020 an equivalent amount of energy savings. Since the alternative approach gives more flexibility in implementing cost-effective energy saving measures as appropriate, Cyprus has chosen this alternative approach. It has been estimated that annual energy savings of 3,316 GWh or 0,285 ktoe have to be achieved for the period 2014-2020.
The same approach will be followed for the period 2021 - 2030, though the annual energy saving obligation that has been recalculated based on the modifications of public building stock. The new annual energy saving obligation for the period 2021 - 2030 is 1,31 GWh or 0,11 ktoe. It has to be noted that the proposed minimum energy performance requirements will require minimum energy class B+ for major renovation of non-residential buildings.

The obligation for the period 2021 - 2030 is scheduled to be fulfilled mainly with the following measures:

1. Deep renovations: Proposal to secure funds from European Cohesion and Development Funds, for the period 2021 - 2027
2. Individual target measures: Measures identified as cost optimum as well as measures combined with maintenance works will be undertaken by the Department of Public Works and the Department of Electromechanical Services mainly funded by national funds.
3. Behavioural measures: The Energy Saving Officer appointed in every public building is entitled to record energy consumption and promote energy efficiency mainly with soft measures. He/she plays a central role in change occupants' habits towards a more rationale use of energy.

Moreover, according to article 6 of Directive 2012/27/EU, the central government is obliged to buy and rent only buildings that at least comply with the minimum energy efficiency requirements. It expected that this measure will change the situation where central government is a tenant in many buildings of poor energy performance.

Finally, a mandatory target was set aiming the improvement of the energy efficiency of the building stock: By 31 December 2020, all new buildings must be nearly zero energy buildings, while this obligation for the public buildings is already in force from 31 December 2019.

(b) Incentive-based Initiatives in the Building Sector

The building sector in Cyprus consumes more than 35% of the total need for energy. On the basis of surveys undertaken by the Energy Service, as well as from the experience gained from the operation of various Grant Schemes, the potential for energy savings in the residential sector through the implementation of proper thermal insulation measures is significant, ranging between 25% and 50%, as the case may be.

A long failure to adopt compulsory thermal insulation regulations for new buildings in Cyprus has resulted in the construction of a large number of buildings of poor to average thermal performance that need increased amounts of energy for maintaining a desired level of comfort. Implementing the Energy Performance of Buildings Directive and the Energy Efficiency Directive is expected to make a significant contribution towards energy savings in the building sector. In addition to thermal insulation, another important field where energy can be saved in buildings is that of heating and cooling systems, regular maintenance of which can ensure substantial energy and environmental benefits[30].

Several studies conducted on behalf of the Energy Service (MECI) have shown that the most cost-effective measures to improve the energy efficiency of existing buildings are:
• Roof thermal insulation
• Heat pumps
• Solar thermal systems for DHW
• LED lighting
• PV systems
• Biomass boilers

Table 5.107 presents the mean payback periods of energy efficiency measures in two main types of residential buildings in Cyprus.

Table 5.107 **Mean payback periods of EE measures in two main types of residential buildings in Cyprus[31]**

	Single Family Houses Payback period (years)	Multi Apartment Buildings Payback period (years)
Deep renovation (to nZEB)	30,7	25,6
Roof insulation	3,6	2,3
Façade insulation	46,1	19,7
Ground level insulation		27,0
Upgrade of window frames	58,6	31,5
Electronic appliances & lighting	8,6	7,3
Heat pump	5,2	6,3
Solar thermal system for hot water production	4,9	4,9

Source MECI, 2017

Over the last years, the government of Cyprus has developed various support schemes and incentives for energy efficiency and RES in order to further support GHG emissions reductions. The majority of these schemes/ instruments are intended to be financed by the national budget, some with assistance from EU funds. The national support schemes that are currently in place for energy efficiency improvement are:

Roof thermal insulation

For owners of existing private residential buildings, a grant scheme for roof top thermal insulation is available. The grant covers 30% of the eligible costs per application, with a maximum grant amount of €1.500.

Further, for thermal insulation of the roof in combination with the installation of PV net-metering systems (residential buildings), an additional grant scheme is available: Regarding the PV system, grants cover € 300 / installed kW; regarding roof insulation, 35% of the eligible costs per application can be covered. The maximum grant amount for the PV system is € 1.200 and € 1.800 for the thermal insulation. Therefore, the maximum grant amount per application is € 3.000.

Solar thermal systems for DHW

For the installation or replacement of solar water heating systems in residential buildings there is a grant available through the Fund for RES & EE (governmental support), namely at € 350 per dwelling and per beneficiary. Furthermore, for solar panels with solar Keymark certification, the grant amount is € 350. For the replacement or installation of solar panels, the maximum grant amount is € 175 per dwelling and per beneficiary.

Energy Audits

The grant scheme for energy audits in SMEs was in place by May 2019, with a total available

[30] Obtained from the report "4th National Energy Efficiency Action Plan of Cyprus" (September 2017)
[31] Obtained from the report "Determination of Cost-Effective Energy Efficiency Measures in Buildings with the Aid of Multiple Indices", (2017)

budget of € 200.000. This government endorsed grant will supplement 30% of the costs of an energy audit, up to a maximum of € 2.000. The scheme is expected to be utilised by 100 SMEs across the country. Based on oral information from MECI, there is no interest from potential applicants on this scheme. Reasons could be that the energy audit a) is not obligatory for SMEs, b) there is no grant scheme or other financial instruments to support SMEs to materialise the investments.

Eco-Management and Audit Scheme (EMAS)

This scheme aims at increasing the environmental performance of SMEs through the establishment of an environmental management system as foreseen in Regulation 1221/2009 / EC. It concerns the provision of subsidies to enterprises that intend to establish an Eco-Management and Audit Scheme (EMAS). It aims to address the environmental impacts of SMEs, as well as to reduce the use of natural resources and improve their energy performance.

The scheme is based on de minimis aid and provides 70% of the cost of providing services for the establishment of an environmental management system with a maximum grant amount of € 2.000. It is also available for the verification and validation of the system with a maximum grant amount of € 500. Transition Costs from ISO 14001 to EMAS can also be funded through additional grants of € 500.

(c) EU Funded (or otherwise funded) Energy Efficiency Programmes

Funds amounting to €53 million have been secured through the European and Structural Funds 2014-2020 Programme, in order to operate schemes and materialize projects, to improve the energy efficiency of existing households, enterprises and public buildings, as well as for pilot projects for high efficiency combined heat and power generation. Funds have also been secured for materializing measures towards sustainable transportation in the period 2014-2020.

As part of the National Operational Programme "Competitiveness and Sustainable Development 2014-2020", the Directorate General for European Programmes Coordination and Development (DG EPCE), acting as Managing Authority (MA), has dedicated resources to the implementation of an Energy Fund of Funds (EnergyFoF) managed by European Investment Bank. The financial product that will be offered through the EnergyFoF is loans to legal or natural persons to materialise investments that aiming to increase the energy efficiency.

The Energy FoF targets in accelerating clean energy investments, including energy efficiency improvements, renewable energy and sustainable urban development projects. Investment to improve energy efficiency in public and private buildings, including SMEs. The Energy FoF is co-financed by European Structural and Investment Funds (ESIF) (€ 40 million), national funds as a national loan from EIB (€ 40 million) and the participated financial intermediaries (€ 40 million). Thus, the total allocated initial amount of EnergyFoF for the period 2020-2023 is €120 million.

The funding will be allocated to the following Special/Thematic Objectives:

- Promotion of entrepreneurship in specific population groups enhancing access to finance. (€10.000.000)
- Increase energy savings in SMEs. (€14.200.000)
- Increase energy savings in public buildings (€7.900.000)
- Increase energy savings in households (€7.900.000)

Upon a successful operation of the fund, it will be used after 2023 in order to continue its operation, utilizing the resources that will be returned to the fund. The establishment of a revolving fund "the Energy Fund of Funds providing soft loans for energy efficiency" is the first step towards a more market-oriented financial support scheme. The success or not of this fund is closely associated with the involvement and cooperation with the domestic banking sector.

(d) Cogeneration: Regulatory Framework, Installed Capacity

Included in the category of net-billing are the combined heat and power (CHP) units, which can be found in any commercial or industrial premises (e.g. commercial or industrial units, public buildings, camps, schools, agricultural and livestock units). The installed power of each CHP system cannot exceed 5MW per installation and the total power for all units allocated to this scheme is 20MW. Until now, there is no interest for this scheme as the tariff regime is bit

(e) Planned policies and New Major Projects for energy efficiency

The table below shows some of the policies and measures that are planned to be implemented during the period 2021 - 2030, in order to contribute to achieving the energy efficiency target for 2030.

Table 5.108 **Planned policies and measures for energy efficiency**

a/a	Policy/Measure	Sector(s) affected
1.	The government is examining a fiscally neutral green tax reform, which can significantly contribute towards transition to an economically and environmentally sustainable development. This is expected to lead to energy savings and will notably reduce the energy dependency of Cyprus.	Agriculture, Industry, Service, Transport, Households, Energy supply
2.	Implementation of the Energy Fund of Funds which will provide soft loans for energy efficiency	Agriculture, Industry, SMEs Public sector, Households
3.	Voluntary commitment from businesses to reduce their emissions by more than 8% by 2030 under the "Business for climate" initiative. It includes specific commitment for improving their energy efficiency.	Agriculture, Industry, Service
4.	Additional floor space "allowance" for new buildings and buildings that are renovated. It is possible to increase the building rate by 5% for energy class A building, and primary energy consumption will not exceed 50 (kwh / m2 year). The aim is to incentivize the construction or renovation of buildings that go beyond NZEB requirements.	Agriculture, Industry, Service, Households | Buildings
5.	Templates and standard procedures for energy performance procurement in public sector will be prepared and disseminated to all public authorities.	Service (Public Sector)
6.	Targeted training and other events to be provided to selected target groups, involved in energy efficiency (implementation and financing).	Agriculture, Industry, Service, Transport, Households, Energy supply
7.	Individual energy efficiency interventions and energy efficiency retrofits in selected governmental and municipal buildings through project funding and Interreg projects CYPRUS-GREECE	Service (Public Sector)
8.	Implementation of individual measures in the building shell, in heating and cooling equipment and energy efficiency retrofits, based on energy performance certificate.	Service (Public Sector)
9.	Implementation of net-billing scheme to commercial/industrial and public administration consumer categories for the installation of high efficiency cogeneration HECHP systems with the prime goal of covering their own consumption.	Industry, Service
10.	Pilot projects (General hospital of Nicosia and the University of Cyprus) for installing high efficiency cogeneration in public buildings.	Service (Public Sector)
11.	Energy efficiency obligation in public purchases and national green public procurement action plan	Service (Public Sector)
12.	Implementation of soft measures (information campaigns, trainings, workshops, etc).	Agriculture, Industry, Service, Households Buildings

a/a	Policy/Measure	Sector(s) affected
13.	Replacing existing lamps / lighting fixtures lighting systems in public roads with new, more efficient ones. The measure concerns the replacement of existing lamps with more efficient ones in the national highway that is under the responsibility of Department of Electromechanical Services, as well as, in local roads that are under the responsibility of the municipalities	Service (Public Sector)
14.	Energy efficiency in electricity infrastructure. This measure aims to decrease system losses and lead to substantial energy savings in the distribution system by upgrading the medium nominal voltage of 11kV to 22kV.	Electricity Sector
15.	Increase of energy efficiency in electricity generation due to the increase of efficiency and the switching of the fuel to natural gas	Electricity Sector
16.	Development of efficient district heating and cooling infrastructure based upon RDF fired cogeneration technologies in tourist areas.	Electricity Sector
17.	Promotion of measures i in water sector (including production, cleaning, pumping, desalination etc) that will achieve end use savings	Service sector, defence sector and industry
18.	Installation of 400,000 electricity smart meters on building stock of the country between the period 2021-2027	Agriculture, Industry, Service, Households
19.	Incentives for the purchase and use of low/zero emission vehicles including the old vehicle scraping scheme and financial incentives for the purchase of electric vehicles.	Transport sector
20.	Installation of charging points and infrastructures for electric vehicles	Transport sector
21.	Specific requirements will be included within the new bus operators' contract such as: • Additional Cost for the Tenderer to Convert their bus fleet to Compressed Natural Gas (CNG), when such fuel source is available in Cyprus and the prerequisites for doing so exist. • Additional Cost for the Tenderer to provide Electric Buses (maximum capacity 22 persons) in Historic City Centres	Transport sector
22.	Installation of telematic system in public bus fleet in order to record data for further optimisation of the public transport system.	Transport sector
23.	Shift of modal share from car trips to sustainable modes of transport - Implementation of Sustainable Urban Mobility Plans including: • Significantly improved bus service (routes, frequency, hours of operation) • Upgrading of infrastructure for pedestrians, cyclists and public transport • Development and implementation of a holistic parking policy Configuration of zero or low emission zones Promotion of a tram system in Nicosia • Development and implementation of high-quality public transport corridors for other cities	Transport sector
24.	Use of vehicles with low or zero emissions	Transport sector

Source: MECI

Energy Legislation & Regulatory Framework

Cyprus has extensive legislation covering the fields of petroleum fuels, the power generation market, natural gas market, hydrocarbons prospection, exploration and exploitation, and the promotion of Renewable Energy Sources. This legislation is summarized as follows:

Renewables

The Energy Service of the Ministry of Energy Commerce and Industry is promoting projects for solar energy (solar-thermal and PV), wind energy (for electricity generation), geothermal energy and biomass-derived energy (for heating and electricity generation), including biofuels, through Law 112(I) 2013 and its subsequent amendments and complimentary Regulations and Ministerial Orders. In addition to the various tasks entrusted to the Energy Service and under section 3 of the Application of European Regulations in the Field of Energy Law 278(I) of 2004, the Energy Service has been nominated as the competent authority for the purpose of implementing the relevant EC regulations which are applicable in Cyprus. Table 5.109 presents the Cyprus regulatory framework regarding Renewable Energy Sources.

Table 5.109 **Legislation and regulatory framework for RES**

Laws	• Law 112 (I) / 2013 - on the promotion and encouragement of the Use of RES
	• Law 157 (I) / 2015 - on the promotion and encouragement of the Use of RES (amending Law)
	• Law 62 (I) / 2018 - on the promotion and encouragement of the Use of RES (amending Law)
Regulations	• R.A.A. 374/2015 - on the promotion and Encouragement of the Use of RES (Certification of Installers for Small scale RES Systems)
	• R.A.A. 248/2015 - on the promotion and Encouragement of the Use of RES (Urgent Fee Calculation Methodology (Annulled)
	• R.A.A. 375/2016 - on the Promotion and Encouragement of the Use of RES (Determination of the Consumption Fee)
Decrees	• R.A.A. 25/2017 - on the promotion and Encouragement of the Use of RES (Criteria to be met by the training providers and the examination bodies regarding the Installers for Small scale RES Systems)
	• R.A.A. 26/2017 - on the promotion and Encouragement of the Use of RES (Examination of Installers for Small scale RES Systems)
	• R.A.A. 211/2018 - on the Promotion and Encouragement of the Use RES (Methodology for Calculating the Share of Energy from Renewable Sources).
Council of Ministers Decision	• No. Decision 78.656 - Abolition of support schemes that provide a guaranteed subsidy price for RES electricity projects and the inclusion of these projects in the competitive electricity market.

Source: EAC

Electricity

By virtue of Part II of the Electricity Market Regulation Law 122(I) of 2003, as amended, (the Electricity Law) the Cyprus Energy Regulatory Authority (CERA) was established as an independent governmental authority with regulatory powers in the energy field, especially the electricity and natural gas sectors. The Electricity Authority of Cyprus (EAC) was established under the provisions of the Development of Electricity Law, Cap. 171, and until the accession of Cyprus to the EU, it had the monopoly for the generation and supply of electricity throughout the island. The liberalisation of the electricity market began with the enactment of the **Electricity Market Law**, which transposed EC Directive 2003/54 into national law. The aforementioned law provides for the regulation of the electricity market of the Republic and, among other things[32] :

- Establishes the Regulatory Authority of Energy of Cyprus (CERA).
- Provides for the creation of a new licensing regime in respect of the generation, transmission, distribution and supply of electricity.
- Establishes the framework for the arrangements between the Transmission System Owner and the Transmission System Operator.

[32] Obtained from EAC (https://www.eac.com.cy/EN/RegulatedActivities/Transmission/legislation-regulations/Pages/default.aspx)

- Regulates access to the transmission system and the distribution system.
- Allows for provision to be made in respect of Public Service Obligations.
- Regulates issues concerning consumer protection.

According to paragraph (1) of article 34 of the Electricity Market Law, any person to carry out any of the following activities related to electricity must be first licensed by the Cyprus Energy Regulatory Authority (CERA):
- Construct a power station or generate electricity
- To supply electricity to eligible customers
- To supply electricity to non-eligible customers
- To carry out any of the responsibilities of the Transmission System Operator in accordance with Article 60
- Perform any of the responsibilities of the Distribution System Operator in accordance with Article 53
- Perform any of the functions of the Transmission System Owner in accordance with Article 46; or
- Perform any of the responsibilities of the Distribution System Owner in accordance with Article 51.

According to paragraph (2) of Article 35, CERA may grant an Exemption from License for the activities referred to in paragraphs (a) and (b) of subsection (1) of Article 34, under such terms and conditions determined by CERA. An exception may be granted for:
- Production of electricity for own use up to 1MW
- Production of electricity from renewable energy sources up to 5MW, or
- Electricity supply by a specific person, the total power of which does not exceed 0,5MW for each plant.

According to paragraph (1) of Article 37, any Application for Submission shall be submitted to CERA in accordance with the rules provided in the Licensing Regulations[33].

Subject to any relevant Ministerial Orders on governmental policy, according to section 38 of the Electricity Law, inter alia, a number of criteria must be taken into consideration objectively and without discrimination by CERA when examining a licence application, which include amongst others:
- The safety of the electricity system, the production facilities and the electricity cable lines.
- The protection of the environment.
- The location of the power stations and the use of land.
- The efficient use of energy.
- The nature of the primary energy source.
- The technical and financial capabilities of the applicant.

Transmission System Operator

The Transmission System Management Unit (the Transmission System Operator or TSO) has been established under section 58 of the Electricity Law. The TSO must ensure, on the basis of objective criteria, that proper allocation of the load and use of the transmission system is made under the licenses, the Rules of Transmission and Distribution or the Electricity Market Rules, and that the operation and management of the electricity trade is compatible with the Electricity Market Rules pursuant to sections 62 (f) and (g) of the Electricity Law.

[33] Obtained from CERA (https://www.cera.org.cy/en-gb/ilektrismos/1169/ilektrismos-adeiodotisi)

Co-Generation

The Laws on the Promotion of Energy Efficiency in Heating & Cooling and co-generation of electricity & heat from 2006 to 2015, through which Article 14 of Directive 2012/27/EU was enacted to national legislation, expand its scope and replace the provisions of Directive 2004/8/EC (for the promotion of electricity and heat co-generation). The new Law amendments aim at the identification and improvement of energy efficiency in the heating and cooling sector through the introduction of binding measures.

Petroleum Products

Petroleum issues are covered by the Petroleum Law, Cap. 272, and the Law on the Specifications of Petroleum Products and Fuels, 148(I) of 2003, and their subsequent amendments (40(I)/2007, 12(I)/2009, 111(I)/2013, 37(I)/2015, 24(I)/2018) we well as the Ministerial Degrees. The Petroleum Law deals with the licenses required and the regulations for the storage of petroleum products. The Law on the Specifications of Petroleum Products and Fuels requires various oil products to meet certain specific standards. These standards are set by Ministerial Orders that rely on specifications adopted at EU level under EU Directives. Specifications on health and environmental matters are included in those Directives, as well as lower limits for the sulphur content of heavy fuel oils and gas oil. Pursuant to sections 5-10 of Law 148(I) of 2003, as amended, the quality of fuel is supervised by the Energy Service through market surveillance by inspectors, the designation of appropriate testing laboratories, the setting of sampling methods and the collection and analysis of the relevant data. Recently various Ministerial Degrees have been adopted in order to meet the national biofuels target (emissions and energy content).

Natural Gas

As initially required by EC Directive 2003/55 Cyprus passed the Natural Gas Market Regulation Law, 183(I) of 2004, as amended (The Law on the Regulation of the Natural Gas Market of 2004 was amended by Laws 103 (I) / 2006, 199 (I) / 2007, 219 (I) / 2012 and 148 (I) / 2018), which constitutes the main legal framework for the regulation of all aspects of the Cyprus natural gas market. In late 2012 amendments were effected, when the national legislation for harmonising with the requirements of the Gas Directive 2009/73/EC.

Transmission, Storage and LNG Facilities

Under section 16 of Law 183(I) of 2004, as amended, undertakings which own facilities connected with the transmission or storage of natural gas, or LNG facilities, are obliged to appoint at least one system operator who is responsible for the operation, maintenance and upgrading of such facilities.

Distribution of Natural Gas

Pursuant to sections 21 and 22 of Law 183(I) of 2004, as amended, undertakings that own distribution systems are required to appoint one or more distribution system operators whose overall task includes operation, maintenance and development under economically viable conditions of a safe, reliable and efficient distribution system, taking into consideration the protection of the environment.

Prospecting ,Exploration and Production

The Hydrocarbons (Prospection, Exploration and Exploitation) Law 4(I) of 2007 (the Hydrocarbons Law) regulates the prospecting, exploration and exploitation of hydrocarbons in conformity with EC Directive 94/22. Furthermore, a Strategic Environmental Assessment (SEAReport) concerning Hydrocarbon Activities within the Exclusive Economic Zone of the Republic of Cyprus was published in November 2008 in accordance with the Assessment of Impact on the Environment of Certain Plans Law 102(I) of 2005. The results and guidelines of the SEA must be respected/followed by all licenses operating in hydrocarbon activities within the Cypriot EEZ. The Regulation on safety of offshore oil and gas operations (no. 424 of 2015) implements the EC Directive 2013/30 and appoints the Department of Labour Inspection as competent authority under this Regulation.

Retail Fuels Pricing

The Petroleum (Establishment of Maximum Retail Pricing in Extraordinary Cases) Law, 115(I) of 2004, as amended (Law 57(I)/2010), provides that the retail price of petroleum products is freely set by the petroleum companies and the petrol station operators, taking into consideration the prevailing international and domestic market conditions. It also gives powers to the Minister of Energy, Commerce & Industry to set ceilings to retail fuels prices on some or all petroleum products for a period of 45 days, whenever the Minister has good reasons to believe that the level of petroleum products prices supplied in the market is excessively higher from what can be justified based on international and national (domestic) conditions in force.

Efficiency and Energy Conservation

Under section 4 of the Regulation of Energy Efficiency of Buildings Law, 142(I) of 2006, as amended, each new building and every building that is substantially renovated must comply with the minimum energy efficiency requirements specified by the relevant Ministerial Order. Moreover, through the Energy Efficiency Law 31(I) of 2009, as amended, Cyprus implemented the 2012 Energy Efficiency Directive, which establishes a set of binding measures to help the EU reach its 20% energy efficiency target by 2020.

Further information on Cyprus's energy legislation framework and regulatory regime you may find in Chapter 8.

5

GREECE

Greece

Economic and Political Background

Greece's GDP contracted at a slower, albeit still pronounced, pace of 7.9% in the final quarter of last year (Q3 2020: -10.5% y-o-y), as the country's second lockdown imposed in early November weighed on activity. All in all, GDP tumbled 8.0% in 2020, contrasting 2019's 1.6% growth and logging the worst downturn since 2011.

Private consumption fell 4.7% in annual terms in Q4 2020, worsening from Q3's 1.6% contraction, as the closure of non-essential businesses for most of the quarter hindered household spending. Meanwhile, fixed investment rebounded, growing 1.6% in Q4 and contrasting the 1.1% decline tallied in the prior quarter. Moreover, government consumption picked up, expanding 7.3% in Q4 (Q3: +4.8% y-o-y).

On the external front, exports of goods and services slid 13.4% in the fourth quarter, softening significantly from Q3's 41.9% nosedive. Conversely, imports of goods and services declined at a more pronounced pace of 9.5% in Q4 (Q3: -5.8% y-o-y). Lastly, on a seasonally-adjusted quarter-on-quarter basis, economic growth moderated to 2.7% in Q4 from 3.1% in the previous quarter.

The economic scenario has likely remained frail in the first quarter of the new year, weighed on by the continuous extension of localized lockdowns throughout Q1. However, the recovery is seen picking up pace from Q2 as national and global vaccine efforts progress, enabling the lifting of local restrictions and kickstarting the all-important tourism industry. However, much hinges on the pace of vaccination and the course of the pandemic, with new Covid-19 variants and the possible extension of restrictions posing key downside risks. IMF estimates that Greece's GDP will expand by 4.1% in 2021, significantly higher than -9.5% in 2020.

Over the course of March 2021, the Greek government announced a series of policy measures to mitigate the severe economic impact of the coronavirus outbreak. On March 19, after previously receiving the green light from creditors to suspend the 3.5% primary fiscal target for this year, Prime Minister Kyriakos Mitsotakis announced that the government would mobilize a total of around €10 billion in a combination of state resources and EU structural funds to help households and businesses cope with the unprecedented crisis imposed by Covid-19.

The measures, which have been unveiled in succession as time progressed, include a one-off €800 payment to workers that have been laid off due to business closures and to those whose employers suffer large financial losses; temporary suspension of tax and social security obligations for affected businesses; a reduction of VAT on certain pharmaceutical products; and tax deferrals for workers and the self-employed.

The government indicated that additional measures were also being contemplated. Meanwhile, in a major move that has come to provide key additional support, the ECB's €750 billion emergency asset purchase scheme unveiled on 18 March included Greek bonds for the first time since the country's sovereign debt crisis. Having been locked out of previous ECB QE operations due to the country's below-investment grade rating, the inclusion of around €12 billion of Greek bonds are expected to ease fiscal pressure somewhat by lowering borrowing costs.

Nevertheless, the outlook has turned bleak. In particular, the vital tourism industry, which has become the engine of the economy and accounts for about a fifth of employment and output, is set to take a massive hit amid plunging bookings, travel restrictions and business closures. Additionally, with economic activity screeching to a halt, this in turn could exacerbate fragilities in the banking system which is already burdened by the highest non-performing loan ratio in the Eurozone.

Energy Policy

National Energy Policy

Greek energy policy is formulated at central government level by the Ministry of Environment and Energy, which is in charge of overall policy formulation. The Greek Energy Policy can be summarized as follows:

- Identify and develop indigenous energy resources in order to ensure the secure, sustainable and constant supply of the country's energy needs.
- Maintain adequate oil and lignite supplies and develop stocks, alternative import sources and routes in order to meet the needs of the domestic energy market at times of crisis.
- Promote the penetration of Renewable Energy Sources in the country's final energy mix, while increasing its overall energy efficiencies and limit its dependence on the utilization of oil and lignite.

Greece's strategy is achieved by establishing and improving the necessary regulatory framework, which focuses on the following:

- Development of alternative energy sources
- Construction of oil, natural gas and electricity interconnectors
- Increased utilization of domestic energy resources and reserves
- Decrease dependence on imported energy sources while building international partnership to mitigate their associated political risks
- Development of renewable energy resources
- Promote the utilization of clean, efficient and environmental friendly technologies
- Enhance the liberalization of the electricity and natural gas markets
- Encourage investments in power generation, upstream oil and gas exploration and midstream infrastructure investments
- Increase energy efficiency in the industrial, transport and residential sector.

Governmental Institutions

The main institutions in the Greek energy sector are the following:

- The **Ministry of Environment and Energy** is principally responsible for the formulation and implementation of the Greek energy policy in the wider context of the country's European and international obligations on the environment and the combat of climate change.
- The **Regulatory Authority for Energy (RAE)** is the independent authority that promotes and safeguards the liberalization of the country's natural gas and electricity markets. Its main responsibility is to supervise the domestic energy market in all sectors, making suggestions to the competent institutions.

- The mission of the **Independent Power Transmission Operator (IPTO or ADMIE)** is the operation, control, maintenance and development of the Hellenic Electricity Transmission System, to ensure the country's supply with electricity in an adequate, safe, efficient and reliable manner, as well as the operation of the electricity market for transactions outside the Day Ahead Scheduling, pursuant to the principles of transparency, equality and free competition.
- The **Public Power Corporation (PPC)** is the leading power generation and supply company in Greece engaged in the generation, distribution and sale of electricity to consumers. Its total installed capacity in Greece is 12.2 GW, with thermal and hydroelectric power plants as well as Renewable Energy Sources (RES) installations both on the mainland and the islands. It is the owner of the power distribution network with Regulated Asset Base of approximately €3 billion, which is operated by its subsidiary company HEDNO S.A. Moreover, it is the largest power supplier with approximately 6.9 million customers all over the country.
- The **Hellenic Electricity Distribution Network Operator (HEDNO)** was formed by the separation of the Distribution Department from PPC S.A. Although it is a 100% subsidiary of PPC, it is independent in operation and management. HEDNO's tasks include the operation, maintenance and development of the power distribution network in Greece, as well as the assurance of a transparent and impartial access of consumers and of all network users in general.
- The **Hellenic Gas Transmission System Operator (DESFA)** is responsible for the operation, management, utilization and development of the National Natural Gas System and its interconnections, in a technically sound and economically efficient way, in order to best serve its Users with safety, reliability and adequacy. Contributing decisively to the security of supply and the diversification of supply sources of the wider region, DESFA also facilitates the development of competition in the Greek energy market, while systematically striving for the reduction of greenhouse gas emissions.
- The **Public Gas Corporation (DEPA)** is a group of companies with presence in the energy sector, actively engaged in the wholesale market, trading, supply and distribution of natural gas. The Hellenic Republic Asset Development Fund (HRADF) holds 65% of DEPA S.A. and Hellenic Petroleum S.A. the remaining 35%.A partial demerger of DEPA's distribution gas activities has already taken place (these activities were transferred to a new legal entity which is named DEPA Infrastructure S.A.). Also, DEPA's participations in international projects were transferred through a spin-off to a new legal entity which is named DEPA International Projects S.A. Following the completion of the partial demerger and spin-off, all current wholesale and retail gas activities of DEPA remain under DEPA under the name of DEPA COMMERCIAL S.A.
- **Hellenic Hydrocarbon Resources Management (HHRM)** was established in 2011 and is headquartered in Athens. It is a state-owned company with the Hellenic State being the sole stakeholder (100%); however, it operates independently as a private-sector economic entity. HHRM is a rapidly growing company providing an innovative and effective management in a wide spectrum of activities: Exploration & Production concessions, overview of the signed lease agreements, offshore safety, and active promotion of Greece as an attractive oil and gas destination to international investors.
- **Renewable Energy Sources Operator & Guarantees of Origin (DAPEEP)** is responsible for renewable energy markets of Greece's National Interconnected System (Transmission System and Distribution Network of Mainland and Interconnected Islands). The company also manages the Guarantees of Origin of Electricity from RES and Combined Heat and Power Units (CHP). DAPEEP is also the auctioneer of the CO_2 Emissions Allowances in Greece, while at the same time operates as the Aggregator of Last Resort (FOSETEK) of RES producers.
- The **Hellenic Energy Exchange (HEnEx)** manages the energy markets of physical delivery and the energy financial markets in accordance with the provisions of Law 4512/2018 and its delegated acts.

Energy Demand and Supply

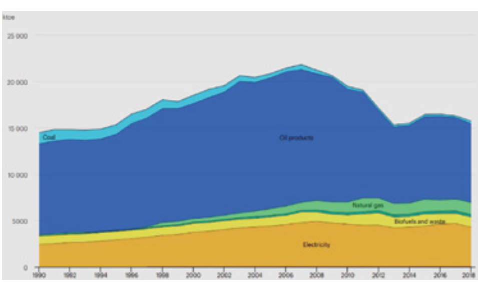
From the early 1990s until now, the Greek energy system has developed in line with the requirements of the national economy, the evolution of other economic activities and the growth of specific sectors, affecting consumer habits, but also European policies on energy, the environment and growth.

National Energy Demand

In the total energy system, domestic final energy consumption was at 15,735 kilotons of oil equivalent (ktoe) in 2018, down 3.5% from 2017. Figure 5.93 depicts the share of the various fuels in final energy consumption over the period 1990-2018. Oil products account for the largest share in final use consumption (54.2% in 2018), followed by electricity (27%), RES (8.7%), natural gas (8.3%) and lignite (1.8%).

The consumption of fossil fuels in final use, namely petroleum products, lignite and natural gas, decreased considerably in 2018 compared to consumption levels in 2007, falling by 36%. This reduction was to a large extent balanced by consumption of natural gas, the use of RES and electricity. Indicatively, consumption of natural gas rose by approx. 54% to 1,297 ktoe in 2018 as compared to 2007. Over the same period, the shares of oil products and lignite were reduced by 41% to 8,493 ktoe and by 47% to 282 ktoe respectively.

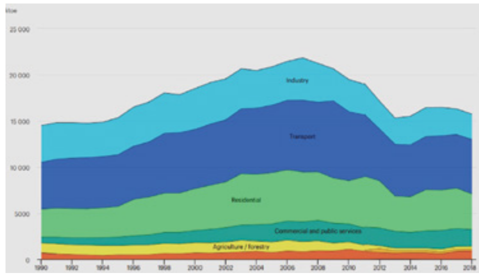
Figure 5.93 **Final Energy Consumption by Type of Fuel in Greece, 1990-2018**



Source: IEA

2018, the largest drop was in the industrial sector, a decline of approx. 40% to 2,739 ktoe, followed by the residential sector and transport, a decline of 29% to 3,845 ktoe and of 24% to 5,897 ktoe respectively in final energy consumption, as compared to 2007.

Figure 5.94 **Final Energy Consumption by Sector in Greece, 1990-2018**

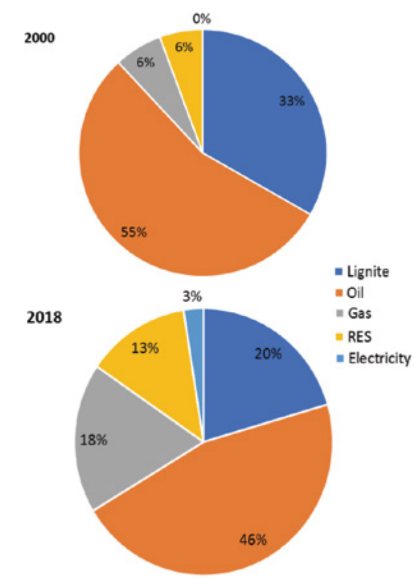


Source: IEA

National Energy Supply

Concerning Greece's total primary energy supply, IEA data for 2018 indicate that oil and oil products account for 46%, followed by lignite (20%), natural gas (18%) and RES (13%), as shown in Figure 5.95. In 2018, the total primary energy supply in Greece stood at 22.6 Mtoe, compared to 27.1 Mtoe in 2000

Figure 5.95 **Total Primary Energy Supply in Greece, 2000 and 2018**



Source: IEA

Energy Balance

Domestic primary energy production decreased from 9.4 Mtoe in 2010 to 7.2 Mtoe in 2018, with substantial fall on the contribution of lignite and important increase in RES use. Lignite remained the country's main source of indigenous energy, accounting for more than 59% of energy production in 2018. It should also be noted that the contribution of biofuels and waste reached about 15% of energy production, while the share of renewables increased from 15.17% in 2000 to 37.76% in 2018.

Source: IEA

Energy Mix

In general, the Greek energy sector is characterized by the existence of limited domestic resources, as Table 5,111 illustrates, resulting in a huge dependence on external energy resources.

Table 5.111 **Greek Energy Mix (Supply and Consumption) in ktoe, 2018**

Fuel type	Production	Imports	Exports
Lignite	4,275	234	0
Crude Oil	201	30,032	-215

Degree of Energy Dependence

As depicted in the next Table, the energy dependence on imported sources in Greece was roughly 71% of the energy consumed in 2018 and an increase of 5.05% was achieved compared to 2009.

Table 5.112 **Energy Dependence in Greece, 2009-2018**

Import dependency (%)	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Solid Fuels	2.0	5.1	2.9	2.3	3.2	2.9	2.9	4.4	4.8	5.1
Total petroleum products	96.8	98.7	93.9	101.4	94.7	99.9	105.5	99.7	98.1	97.9
Gas	99.7	99.9	100.0	100.3	100.0	99.3	99.9	99.2	100.5	100.7
Total	67.3	68.6	64.7	65.9	61.8	65.5	71.0	72.9	71.3	70.7

*Energy dependency shows the extent to which an economy relies upon imports in order to meet its energy needs. The indicator is calculated as net imports divided by the sum of gross inland energy consumption plus bunkers.
Source: Eurostat

The Energy Market

Greece's energy market covers activities in oil (upstream and mainly downstream), gas imports and distribution as well as electricity generation, transmission and distribution. The market also includes activities, covering solar thermal utilization and electricity generation for solar PV, wind and small hydro. There is limited activity in geothermal and biomass utilization. Furthermore, there is an increasingly input activity in energy efficiency applications for buildings.

OIL AND PETROLEUM PRODUCTS

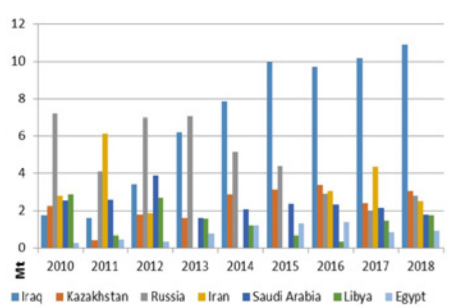
(a) Oil Production, Imports and Exports

The production of crude oil in Greece in 2018 was insignificant (0.21 million tons, Mt) as compared to domestic final consumption of oil products at approx. 8.8 Mt in the same year. Indeed, it was derived from three oil fields (Prinos, Prinos North and Epsilon) of which the production, though increased by 450% over the last eight years, remained small at 3,300 barrels per day in 2019, when Greece consumes approx. 7.3 million tons or 142,000 barrels a day (average daily consumption of crude oil in the country). The company Energean is the sole oil producer in Greece. The three active oil fields, Prinos and Prinos North and Epsilon, are located offshore the island of Thasos in the Northern Aegean.

Therefore, Greece depends on imports of large quantities of crude oil in order to cover its needs. Iraq was the biggest crude oil supplier to Greece in 2018 with 10.9 Mt, followed by Kazakhstan and Russia with 3.1 Mt and 2.8 Mt respectively (see Figure 5.99). Imports from Iraq only accounted for 46% of total crude oil imports in Greece in 2018, which amounted to approx. 23.7 Mt.

Imported crude oil is refined into oil products at four domestic refineries. Greece has increased considerably its refining capability in recent years, with exports of oil products at 20 million tons in 2018, according to IEA data[1]. Greece also imports oil products, with imports at 3.8 million tons in 2018.

Figure 5.99 **Greece's Crude Oil Imports by Country, 2010-2018**



Source: Greece's Ministry of Energy

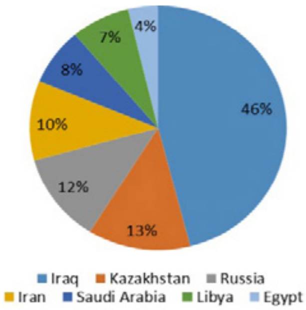
Figure 5.100 **Greece's Crude Oil Imports by Country, 2018**

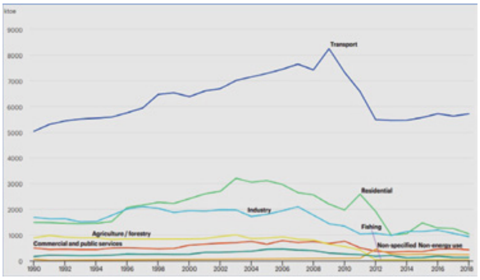


Source: Greece's Ministry of Energy

(b) Oil Consumption

Over the period 2005-2015, oil consumption in Greece recorded a sudden drop by one third due to the economic crisis of 2008 (see Figure 5.101) and the Greek financial crisis that ensued, especially after 2009. In recent years, however, oil consumption recovered, rising by 9% between 2013 and 2015, mainly in transport and to an extent in the residential sector.

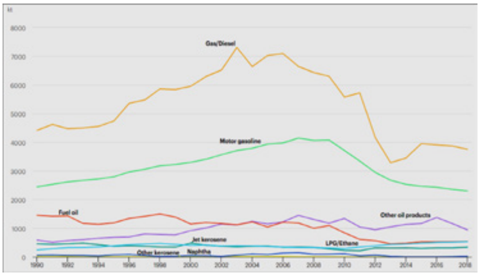
Figure 5.101 **Oil Consumption by Sector, 1990-2018**



Source: Greece's Ministry of Energy

The transport sector consumed 5.6 Mtoe of oil in 2017 or 50% of total oil consumption. Road transport accounts for 87% of total oil consumption in transport, followed by domestic shipping at 10% and smaller shares for domestic air and railway transport. The transport sector mainly consumes diesel and gasoline, which together account for 62% of total oil consumption in Greece (see Figure 5.102).

Figure 5.102 **Oil Consumption by Product, 1990-2018**



Source: Greece's Ministry of Energy

Approximately one third of the diesel is consumed in the residential sector for space heating. Heating oil represents one third of total residential energy consumption, the fourth highest share among IEA member-states. Residential oil consumption was considerably higher before the financial crisis (2009-2018). More specifically, it declined by 62% between 2011 and 2014, mainly due to a conjunction of high heating oil prices, reduced household income, and increased penetration of natural gas use because of a change in government policy (change of fuel in favour of biomass and natural gas). Consumption rose again in 2015.

Furthermore, Greece, in comparison to other countries, consumes a higher percentage of oil in power generation. Oil production units located on the islands accounted for 11% of total electricity generation in 2015, which was the highest among all IEA member-states. This is because many of the Greek islands are not yet connected to the mainland power grid but are supplied by autonomous production stations operating with oil-fired units (diesel and fuel oil).

(c) Upstream Sector – Domestic Exploration and Production

In 2018, oil production from the Prinos oil field, which is in operation since 1981, was minimal at 0.21 million tonnes, corresponding to 1.5 million barrels of oil.

In Greece, the most significant development in the hydrocarbon sector over the past year was the signing in early July 2019 of agreements for four large concession areas with four joint ventures of Greek and foreign companies for the areas south and southwest of Crete and the Ionian Sea. The four concession areas in Greek territory in 2019 are depicted in Table 5.113; the relevant agreements were ratified by Parliament on October 10, 2019.

1. For the offshore area **"Ionian"** in western Greece, an agreement was signed on April 9, 2019 between the Greek State and the Repsol-HELPE joint venture. Also signed on the same day was the agreement for "Block 10 Ionian Sea" (in the Gulf of Kyparissia) between the Greek State and HELPE.
2. For concession and exploration and exploitation rights of the offshore areas **"Southwest and West of Crete"**, the agreements were signed on June 27, 2019. Earlier, in the first days of July 2018, it was announced that the Total-ExxonMobil-HELPE joint venture had been formally declared as the successful bidder in the international tender held by the Ministry of Energy.

Table 5.113 **Hydrocarbon Concessions and Contracting Companies in Greece, 2019**

Date of publication in the Govt. Gazette (date when the agreement comes into effect)	Block	Location	Stage	Lessees, assignee, rates of participation
10/10/2019	Southwest of Crete	Offshore	Research	Total (40%, Assignee), ExxonMobil (40%), HELPE (20%)
10/10/2019	West of Crete	Offshore	Research	Total (40%, Assignee), ExxonMobil (40%), HELPE (20%)
10/10/2019	Ionian Sea	Offshore	Research	HELPE (50%, Assignee), Repsol (50%)
10/10/2019	Block 10	Offshore	Research	HELPE (100%)

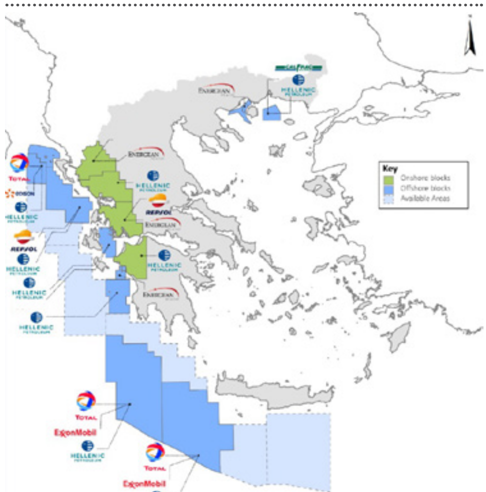
Source: HHRM

However, the required seismic surveys in the above offshore blocks southwest and west of Crete are expected to be delayed due to the spread of the coronavirus pandemic, while the dramatic fall in oil prices has resulted in negative market sentiment delaying further any real progress. The exact date will be set depending, inter alia, on the availability of special seismic survey ships and weather conditions. It is worth noting that the initial seismic surveys for the Crete area appear encouraging, especially regarding the "Talos" field, which has a geological structure similar to that of the well-known Zohr field off the coast of Egypt.

Another important development was the announcement of the acquisition last February by Energean of the 50% share held by the French company Total in offshore Block 2 in the Ionian Sea. Since Energean is also in the process of acquiring Edison E&P, which holds 25% of exploration and exploitation rights over Block 2. The deal has been completed a year ago, now Energean holds 75% and Hellenic Petroleum the remaining 25%.

Energean has said that exploration up to now in that area indicates that "Block 2" includes part of a wider potential target, extending by 60% in Greek territory and by 40% in Italian, in a maritime area where Edison is active.

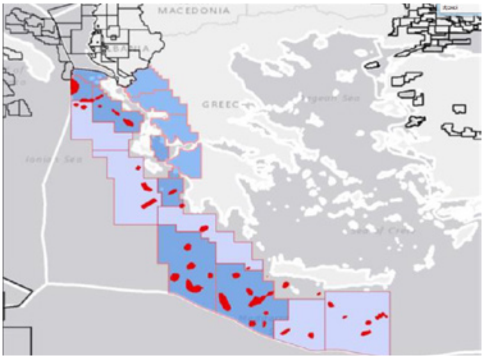
Map 5.24 **Concession Areas in Greece, December 2019**



Source: HHRM

According to HHRM, domestic hydrocarbon exploration activities are not only limited to the above areas that are already the concession areas, but also extend to offshore blocks that are available for concession. During the last months of 2019, the geological features of these blocks in the central Ionian Sea and south Crete were presented by HHRM to the international market and fora and have attracted the interest of international oil companies.

Map 5.25 **Hydrocarbon Fields-Targets in the Ionian Sea and Crete, 2019**



Source: HHRM

Regarding the area to the west and south-west of Crete, HHRM notes that the potential targets are located in rocks hidden under the seabed, while depths exceed by far 1,500 metres.

Average water depth in these areas exceeds 2,500 metres and in many cases it is around 3,500 metres. Technology for drilling at such depths is expected to be available over the next three years, and the companies will decide then whether or not to proceed with exploratory drilling. It is worth mentioning that areas that appear of interest do not necessarily "conceal" hydrocarbon quantities; this can only be confirmed with drilling operations. However, it is encouraging that in neighbouring countries, featuring similar geomorphology, hydrocarbons have been discovered and are already being exploited.

(d) Downstream and Midstream Sectors Infrastructure

Oil Pipelines

Greece has two oil pipelines, only one of which is operational. The 53 km Aircraft Fuel Supply Pipeline links HELPE's Aspropyrgos refinery to Athens International Airport at Spata. It is operated by the Athens Airport Fuel Pipeline Company, which also financed and constructed the pipeline. With a capacity of 2.6 mcm per annum, it is considered sufficient to accommodate the potential growth of air traffic well into the future.

The second, a 210 km crude oil pipeline, links HELPE's Thessaloniki refinery with its Okta refinery in North Macedonia. The pipeline has not been in operation since 2013. Plans to build a pipeline to link Greece with Bulgaria to offer an alternative supply route for Russian and Caspian oil have been discussed for over a decade without much progress. Most crude oil and products are moved by trucks and ships within Greece, while supplies to power plants are transported by train.

Oil Terminals

There are ten oil terminals in Greece, with a total loading capacity of 0.8 mcm per day and a total discharging capacity of 2.3 mcm per day. Seven of them are located in the Attica Area (including Athens) and three are in the Thessaloniki area. Six oil terminals (Aspropyrgos, Elefsina, Thessaloniki, Aghioi Theodori, Pachi, and Agia Triada) receive crude oil; four of these are located near the refineries. The country's total crude oil discharging capacity is around 1.6 mcm per day.

Oil Storage

Greece's combined storage capacity was around 10.2 mcm (equivalent to 64 million barrels) in 2018, and was used for industry operations and mandatory industry stocks. This shows that the country has sufficient storage capacity to meet the IEA 90-day obligation, which required Greece to have 3.5 mcm (22 million barrels) of oil storage capacity in 2018.

Oil Refineries

Imported crude oil is refined into oil products at four domestic refineries (see Table 5.114). The three refineries that belong to HELPE (Hellenic Petroleum S.A.) are located in Aspropyrgos, Elefsina and Thessaloniki and represent approx. 65% of the country's total refining capacity, with crude oil and oil product storage tanks having a total capacity of 6.65 million cubic metres. The refinery of Motor Oil at Agioi Theodoroi near Corinth produces the rest.

In 2019, the utilisation rate of HELPE's refineries was negatively affected by the completion of the current cycle of operation at the refineries of Aspropyrgos and Elefsina and the temporary suspension of operation for maintenance works at the Elefsina refinery, which were completed in the fourth quarter. Consequently, the production of HELPE's refining sector recorded a slight drop and amounted to 14.2 million tons in 2019. HELPE's sales were impacted commensurately and amounted to 15.2 million tons; exports stood at 7.9 million tons or 52% of total sales, and sales of aviation and shipping fuel were up 5% at 2.8 million tons. The production of the Motor Oil refinery also recorded a slight decline in 2019 compared to 2018 and amounted to 12.1 million tons, while sales stood at 14.4 million tons at approx. the same levels as in 2018. It is worth noting that Motor Oil's lower production and quantity of crude oil and raw materials processed in 2019 compared to 2018 was due to the scheduled periodic maintenance of the refinery's units. The Motor Oil refinery has also acquired the flexibility to process a broad range of crude oil types; thus, contributing to import diversification. Furthermore, the refinery can now easily switch between diesel and gasoline production and adapt to seasonal changes in Greece's demand. The upgrade and modernisation works have placed the refineries among the most profitable in Europe, and their specifications are modern and environment-friendly.

Table 5.114 **Refineries in Greece**

	Hellenic Petroleum (HELPE) S.A.			MOTOR OIL
Ownership	Paneuropean Oil and Industrial Holdings S.A: 42.6% Hellenic Republic Asset Development Fund: 35.5% Institutional investors: 15.3% Private investors: 6.6% Free float: 23.5%			Petroventure Holdings Limited: 40,0%; Doson Investments Company: 8,1%; Free float: 51,9%

Sources: IENE, HELPE and Motor Oil

Based on data by the Hellenic Petroleum Marketing Companies Association (SEEPE), domestic market's fuel sales were up 0.45%, from 6,655,720 tons in 2014 to 6,685,490 tons in 2018. More specifically, the domestic market's sales of gasoline declined by 8.98% (2014: 2,516,270 tons - 2018: 2,290,214 tons), sales of heating oil grew by 10.62% (2014: 2,363,892 tons - 2018: 2,614,881 tons), while fuel oil sales declined by 13.66% (2014: 208,029 tons - 2018: 179,616 tons). LPG sales rose by 17.28% (2014: 437,955 tons - 2018: 513,623 tons) due to increased use of autogas, kerosene sales dropped by 16.57% (2014: 3,145 tons - 2018: 2,624 tons), and asphalt sales dropped by 27.44% (2014: 158,683 tons - 2018: 115,141 tons). The reduction in the consumption of petroleum products in 2018 compared to 2017 was mainly due to the reduced consumption of heating oil and unleaded gasoline.

Map 5.26 **Oil Infrastructure in Greece**

Source: IEA

(e) Security of Supply

Greece meets its stockholding obligation to the IEA and the EU by placing a stockholding obligation on industry. According to Law 3054/2002 (on organisation of the oil market) and Law 4123/2013 (on maintaining minimum stocks of crude oil and petroleum products), all oil importers and large end users (such as power plants) are required to hold oil stocks equivalent to 90 days of their net imports made during the previous year. Industries are required to hold compulsory stocks in facilities that have been certified as emergency stock storage tanks. Emergency stocks can be held in the same facility as industry stocks; in practice, compulsory stocks are commingled with operational/commercial stocks.

All the storage facilities owned by refineries are certified tanks for emergency stocks. HELPE operates around 70% of the total Greek storage facilities, and it is the country's largest refining company. Part of the storage facilities is used for maintaining stocks for third parties in the context of European Directive 2009/119/EC. Foreign companies with term/spot commercial storage agreements and clients who require oil storage capacity to obtain retailing licenses can make use of the available storage capacity.

(f) Planned new projects

Currently, there is no planned new project in the Greek oil sector. In the map shown earlier regarding oil infrastructure in Greece, the green-dotted line is referred to the Burgas – Alexandroupoli oil pipeline that was expected to be used for transporting Caspian and Russian oil from the Bulgarian Black Sea port of Burgas to the Greek port of Alexandroupolis. The only planned 300-km pipeline construction was suspended in December 2011 by the Bulgarian government due to environmental and supply concerns.

NATURAL GAS

The Greek gas market appears to have recovered in 2019, after the extended period of financial crisis. In parallel, implementation of the actions outlined in the Gas Market Roadmap 2017-2022[2] continued; especially, those that aim at a transition to a fully deregulated market (e.g. reforms in the retail and wholesale markets, and corporate restructuring of supply companies).

(a) Natural Gas Consumption, Imports and Exports

Based on data provided by DESFA[3], total consumption of natural gas in Greece in 2019 amounted to 57.4 TWh or 4.9 billion cubic metres, up 10% compared to the respective figure for 2018 and up 79% compared to 2014. Therefore, gas consumption in 2019 was the highest since it was first introduced in the country. It is worth mentioning that in 2019 Greece exported to Bulgaria gas quantities amounting to 7.7 TWh.

Figure 5.103 **Natural Gas Consumption, Imports and Exports in Greece, 2019**

	MWh	Nm³
Natural Gas Consumption	57.407.326	4.943.457.468
Natural Gas Imports		
LNG (Regasification)	31.008.180	2.635.382.903
TR (Turkey)	8.108.942	695.244.866
BG (Bulgaria)	25.667.513	2.261.454.873
Natural Gas Exports		
BG (Bulgaria)	7.701.872	678.579.018

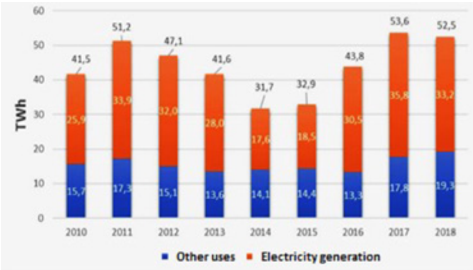
[3] https://www.desfa.gr/userfiles/pdflist/DERY/TT/Leit_Stoix_ESFA_2019.pdf

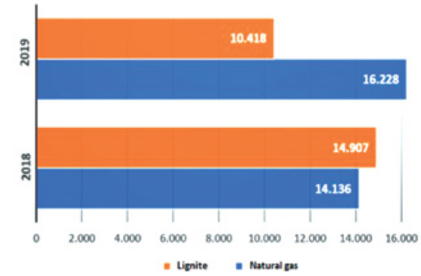
Figure 5.104 **Evolution of Gas Consumption in Greece, 2010-2018**



Source: RAE

The highest percentage of natural gas in 2019, as in all past years, was consumed in power generation by PPC's thermal units and private electricity producers. Indeed, the role of natural gas in power generation rose considerably in 2019 as compared to 2018. As shown in Figure 5.104, the production of units using natural gas as fuel increased by 15% in 2019 compared to 2018; on the contrary, the electricity generation from lignite was reduced by 30% compared to 2018.

Figure 5.105 **Annual Production (GWh) of Thermal Stations in Greece, 2018-2019**



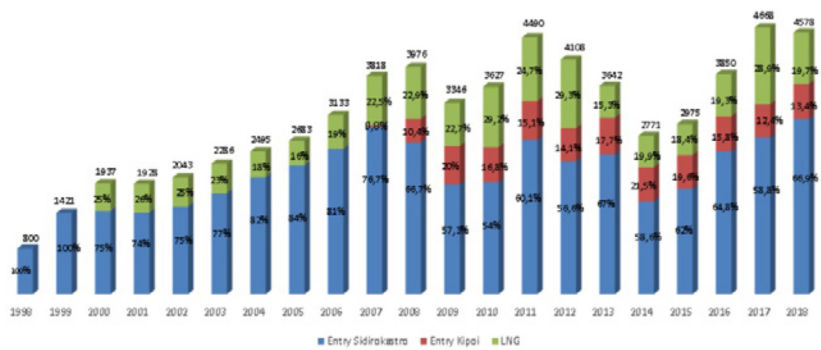
Source: IPTO

The penetration of natural gas in Greece remained at very low levels in 2018 (8%), compared to the average in other European countries, where it reaches 55% and thus, electricity generation is still the main factor in Greece's gas demand.

(b) Sources of Natural Gas Supply in 2019

2019 was a reference year for the evolution of the market share between piped gas and imported LNG into Greece. Figure 5.106 depicts the contribution share of piped gas and LNG over the period 1998-2018.

Figure 5.106 **Evolution of Gas Imports into Greece, 1998-2018**



Source: DESFA

These shares changed significantly in 2019 compared to 2018. More specifically, LNG accounted for 55% in 2019 against 45% for piped gas, when the maximum share of LNG had been 29% in 2010 and 2012. In 2018, LNG accounted for 20%. It is the first time that LNG exceeded in quantity the gas supplied via pipelines.

Source: DESFA

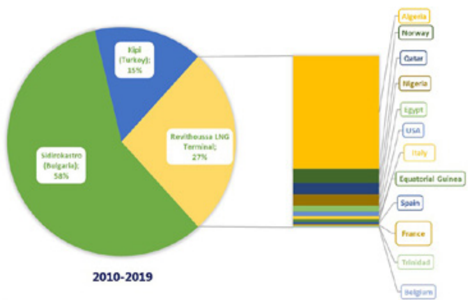
(c) Natural Gas Infrastructure

The natural gas transmission system has three entry points: two at the north and north-eastern borders (Sidirokastro and Kipi), connecting Greece with the Bulgarian and Turkish gas networks, and one in southern Greece (Agia Triada), linked to the LNG terminal. The biggest natural gas infrastructure of Greece is the LNG terminal on Revithoussa Island. It plays a key role in the operation of the natural gas transmission system, especially during security of supply crises. Currently, there is no underground gas storage in Greece. The country's only storage facility is located at the Revithoussa LNG terminal. However, the government has plans for underground storage in the exhausted Kavala offshore gas field.

Revithoussa LNG Terminal

In January 2019, the commercial operation of the third storage tank of the terminal commenced. In parallel, in the context of the second upgrade of the terminal, the capacity for LNG gasification increased, and there is now the possibility of mooring larger LNG tankers, up to Q-MAX size (in practice, the largest LNG tankers in the global market can now be accommodated). Based on the operational data of the LNG terminal for 2019, it is clear that the target of handling greater LNG quantities has been achieved; thus, improving the liquidity of the market and strengthening the country's security of gas supply. According to DESFA's data[5], there was an increase both in sources of gas supply and in the number of unloadings after the upgrade of the terminal (see Figure 5.109).

Figure 5.109 **Countries of Origin of LNG Imports at the Revithoussa Terminal, 2010-2019**



Source: DESFA

Figure 5.110 **Number of LNG Unloadings Before and After the Upgrade of the Third Tank**

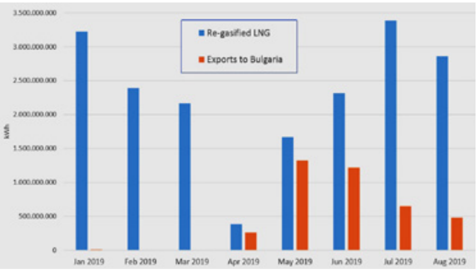
[5] Avlonitis, G. (2019), "Wholesale market and infrastructure", RAE Day Conference (84th TIF), http://www.rae.gr/site/file/categories_new/about_rae/factsheets/2019/gen/16092019?p=file&i=1

Lastly, the upgrade of the LNG terminal also contributed (increase from 1 mcm/d to 5.5 mcm/d after the upgrade[6]) to realising gas exports to Bulgaria via the Sidirokastro Reverse Flow Exit Point, as shown in Figure 5.111.

Figure 5.111 **The Role of the Upgraded LNG Terminal in Cross-Border Trade**

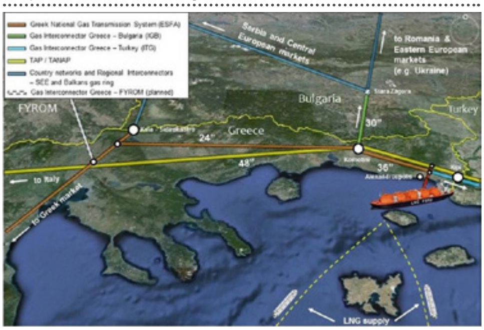


Source: DESFA

Alexandroupolis FSRU

The project will consist of one Floating Storage Regasification Unit (FSRU), which will be permanently moored at a fixed point at a distance of 17.6 km south-west of Alexandroupolis harbour and 10 km from the coast at Makri.

Map 5.27 **Alexandroupolis FSRU**



Source: Gastrade

Gastrade, a company of the Copelouzos Group, is developing the project in Alexandroupolis; the budget is €380 million and the annual capacity is 5.5 bcm. The project constitutes a departure in terms of national energy policy, but is also of high significance for Europe. It is part of the EU's policy for Central and South-eastern Europe Energy Connectivity (CESEC) with the European Natural Gas System via the development of a Vertical Corridor and has been included in the updated list of Projects of Common Interest of 30 October 2019[7].

The first non-binding phase of the Market Test was successfully completed on December 31, 2018, in which 20 companies expressed their interest for 12.2 bcm per year. On December 23, 2019, DEPA's Board of Directors approved the participation of the company in Gastrade's share capital with a share of 20%. On January 8, 2020, the participation of Bulgartransgaz EAD in Gastrade's share capital was also approved with a share of 20%, and the related agreement was signed in late August. Thus, the shareholder composition now stands as follows: Copelouzos Group 40%, GasLog 20%, DEPA 20% and Bulgartransgaz 20%.

On January 10, 2020, the second phase of the Market Test went ahead, whereby interested parties were invited to submit binding offers by March 24, 2020, after a third extension was given. By that deadline, binding offers for total quantities of 2.6 bcm per year had been submitted, with a timetable of 5 to 15 years. Binding offers were submitted by DEPA and PPC on the Greek side, the Bulgarian company Bulgartransgaz, and two private trading companies from Romania and Serbia.

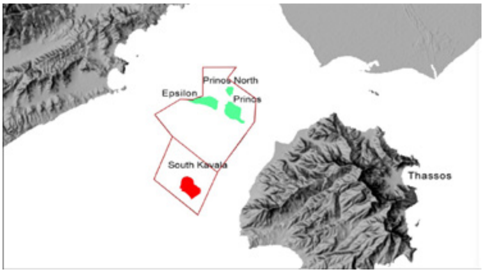
In early March 2020, three groups submitted offers for the construction of the pipeline and other works that will connect the Alexandroupolis FSRU with the National Natural Gas Transmission System. More specifically, binding offers were submitted by the joint venture of the Italian firm Saipem with the Greek construction company TERNA and the Dutch companies BOSKALIS and VAN OORD. According to the expected project's timetable, the Final Investment Decision (FID) is expected in the fourth quarter of 2020. The construction of the FSRU will last two years and the commencement of commercial operation is scheduled for early 2023.

[6] DESFA (2017), "10-year Forecast for Technical Capacity of Natural Gas Transmission System Entry Points", https://www.desfa.gr/userfiles/pdflist/anathewrimenes_texn_dynamikotites_07-2017-gr-v2.pdf
[7] ANNEX to COMMISSION DELEGATED REGULATION (EU) amending Regulation (EU) No 347/2013 of the European Parliament and of the Council as regards the Union list of projects of common interest SWD(2019) 395 final.

South Kavala Underground Gas Storage (UGS)

This project, having a budget of €300 million - €400 million, aims at exploiting the depleted offshore gas field of South Kavala (used by the company Energean – remaining gas reserves assessed at 0.073 bcm) as an underground gas storage facility. It is located in the Gulf of Kavala, 11 km south of the Prinos oil field, at a depth of 1,700 metres.

Map 5.28 **The Red-coloured Area is the Depleted Natural Gas Field in South Kavala**



Source: Energean

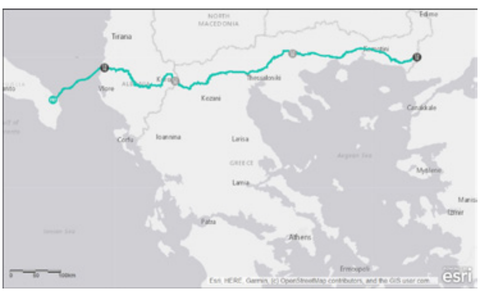
The South Kavala UGS is an energy infrastructure project that will enhance the security of gas supply at national and European level for the benefit of the end consumer. It offers long-term capability for the storage of natural gas, in contrast to the Revithoussa LNG terminal, which is suitable only for short-term storage. It should be noted that Greece is the only EU country that has no permanent underground gas storage facility even though 40% of the country's electricity generation is now based on natural gas. European countries store at minimum 20% of their annual gas consumption in underground gas storage facilities. According to the preliminary plans of the project, the capacity of the UGS is assessed at approx. 1 bcm. Annual volume throughput is assessed at 360 million Nm3 or 720 million Nm3, for one or two cycles per year, respectively. It is worth mentioning that the project has been included in the list of Projects of Common Interest (PCI) that was adopted on October 30, 2019 (Cluster increase storage capacity in South-Eastern Europe) by the European Commission and the member states at the meeting of Regional Teams for the PCIs.

On March 10, 2020, a Joint Ministerial Decision[8] was issued for commencing the procedure of exploiting the field. More specifically, the Hellenic Republic Asset Development Fund (TAIPED) will conduct an international tender for the concession of rights for the construction, maintenance, operation and exploitation of the field as a UGS for a period of up to 50 years. On June 29, 2020, TAIPED announced[9] the commencement of an international tender procedure for the concession of rights for the use, development and exploitation of the underground natural field at the location of the almost depleted gas field "South Kavala", with the aim of converting it into a gas storage facility. On August 11, 2020, TAIPED announced[10] an extension to September 30, 2020 of the deadline for expressing interest for the concession agreement for the use, development and exploitation of the underground natural field at the location of the natural gas field "South Kavala". Two schemes have expressed their interest about the project, Energean and DESFA- GEK Terna.

Trans Adriatic Pipeline (TAP)

The Trans Adriatic Pipeline (TAP) project involves the construction of a gas pipeline that will transport gas from the area of the Caspian Sea to Europe. TAP is now connected to the Trans Anatolian Pipeline (TANAP) at the Greek-Turkish border and then continues through northern Greece, Albania and the Adriatic Sea before terminating at the coast of southern Italy, where it is connected to the Italian natural gas system.

Map 5.29 **TAP Route**



Source: TAP AG

[8] https://diavgeia.gov.gr/doc/%CE%A9%CE%99%CE%93%CE%A74653%CE%A08-6%CE%95%CE%A5?inline=true
[9] https://www.hradf.com/storage/files/uploads/yafa-e-narkshdiagwnismoy-29062020.pdf
[10] https://www.hradf.com/storage/files/uploads/yafa-e-narkshdiagwnismoy-29062020.pdf

The TAP pipeline will be connected with the Greek Natural Gas System and the IGB pipeline. It will also provide new Exit Points for supplying gas distribution networks in Western Macedonia, and will have reverse flow capability for transmitting gas at competitive prices via the Italian system. On July 1, 2019, the project operator conducted a Market Test, in accordance with the guidelines approved by the Regulatory Authorities of Greece, Italy and Albania. The Non-Binding stage was completed on October 21, 2019 with the publication of the Demand Assessment Phase Report.

On March 30, 2019, the installation of the first pipelines of the project's offshore section was completed successfully, with a length of 105 km, connecting the coasts of Albania and Italy. Construction work on that section started in October 2018. On November 25, 2019, the introduction of natural gas in a 2-km section of the pipeline (between Evros and the Kipoi Compression Terminal)[11] commenced. This is the initial stage of the commissioning process, and aims at ensuring that the project is fully safe and ready for operation. According to data[12] provided by the project operator, the project was 95% completed by late April 2020.

On January 20, 2020, the three operators involved in natural gas transmission systems (TAP, SRG and DESFA) invited those interested in participating in a public consultation concerning a proposal for increased capacity for the TAP pipeline up to February 21, 2020. In early June 2020, the three operators announced that the binding phase of the market test for increased capacity is expected to be realised in July 2021, rather than in January of that year as initially scheduled, so that more time is given for the energy markets to recover, following the coronavirus pandemic.

Interconnector Greece - Bulgaria (IGB)

The project of the Greek - Bulgarian Interconnector (IGB) consists of a pipeline with a length of 182 km that begins in Komotini and ends in Stara Zagora, effectively connecting the gas networks of Greece and Bulgaria, while it will have reverse flow capability. The project has been included in the latest list of PCIs of October 30, 2019. In addition, the Greek - Bulgarian interconnector is included in the list of priority projects of the Central and South-Eastern Europe Gas Connectivity (CESEC) initiative. It is anticipated that gas transmission to the markets of Bulgaria and South-Eastern Europe will be increased via the IGB.

Map 5.30 **IGB Route**

Source: ENTSOG

On April 3, 2019, the EU approved financing of €39 million for the construction of the project. On July 18, 2019, RAE granted to the company ICGB AD (50% Bulgarian state company BEH – 50% YAFA Poseidon S.A.) pursuant to its decision No. 671/2019, a licence for an Independent Natural Gas System (ASFA).
The ASFA concerns the Greek section of the Greek - Bulgarian interconnector (IGB). According to the above decision, the IGB will be connected with the National Natural Gas System (ESFA), the TAP natural gas transmission system and Bulgaria's natural gas transmission system, and will strengthen the position of Greece as regional energy hub, contributing to the increase of competition in Greece's natural gas market and creating benefits for both domestic and Bulgarian consumers.

[11] TAP (2019), "TAP Introduces First Natural Gas into the Greek Section of the Pipeline as part of its Testing Phase", https://www.tap-ag.com/news-and-events/2019/11/26/tap-introduces-first-natural-gas-into-the-greek-section-of-the-pipeline-as-part-of-its-testing-phase
[12] TAP (2020), "Project progress", https://www.tap-ag.com/pipeline-construction/project-progress

In early October 2019, the Regulatory Authorities of Greece and Bulgaria jointly approved the project's Operation Code and Pricing Regulations.

On October 10, 2019, Bulgaria's Energy Minister Mrs. Temenuzhka Petkova and the Minister of the Environment and Energy of the Hellenic Republic Mr. Kostis Hatzidakis signed an Intergovernmental Agreement setting the terms of construction and operation of the pipeline by the company ICGB AD.

Construction work on the pipeline started on October 28, 2019 and will last 18 months. The pipeline has been designed in order to operate in two phases. In the first phase, expected to start commercial operation on July 1, 2021, the capacity of the pipeline will be 3.0 bcm per year, of which 2.7 bcm will be offered for long-term products and 0.3 bcm for short-term products. In the second phase, subject to additional commercial interest, the capacity of the pipeline can be increased up to a total of 5 bcm per year with the addition of a compressor, of which 4.5 bcm will be offered for long-term products and 0.5 bcm for short-term products.

Poseidon Turkey - Greece - Italy Pipeline (ITGI)

The Poseidon Greece - Italy Interconnector consists of two sections: (a) the onshore section, with a length of approx. 760 km, which begins at the Greek - Turkish border at Kipoi and passes through the Regions of eastern Macedonia and Thrace, central Macedonia, Western Macedonia, Thessaly and Epirus before terminating at the coast of Thesprotia; and (b) the offshore section of the project, with a length of approx. 210 km, which connects the coast of Thesprotia with Otranto in Italy.

The offshore section of the project (Greece - Italy) has been included in the latest list of PCIs, of October 30, 2019. In the Development Study 2020-2029 prepared by DESFA, the final investment decision of this project will be reached after conducting a market test. According to the decision of March 26, 2020 13, the installation and route of the onshore section of the Greek part of the pipeline, with a length of 8.2 km, from the Metering and Compression facilities in Thesprotia to the landing point of the sea route to Epirus were set. The main concern about this project is whether and to what extent is directly competitive with TAP or whether it constitutes an additional route for potential Russian gas exports to Europe.

Map 5.31 **IGI Route**

Source: DEPA

Interconnector Greece - North Macedonia (IGNM)

The construction of this pipeline, with a budget of €47.8 million and an annual capacity of 3 bcm, aims at interconnecting the natural gas systems of Greece and North Macedonia and achieving a diversification in North Macedonia's gas supply sources, which until recently were entirely dependent on the Trans Balkan Pipeline and since January 2020 on Turkish Stream, via Bulgaria.

The access to ESFA and especially to the Revithoussa terminal and to gas via TAP will enhance competition; thus, potentially leading to lower gas supply prices in the neighbouring country. At the same time, this project promotes the development of a regional gas market and the entry of more users, contributing to the growth of the Greek gas hub, which in turn will result in better gas

[13] https://diavgeia.gov.gr/doc/%CE%A8%CE%9B%CE%A5%CE%A84653%CE%A08-%CE%983%CE%A7?inline=true

prices in the Greek market too. It will also contribute to an increase in the use of Greece's infrastructure, such as the Revithoussa LNG terminal, with the aim of lowering system user charges in the long term. The project within Greek territory consists of the construction of a 54.3 km pipeline beginning at Nea Mesimvria and extending to the border with North Macedonia.

Map 5.32 **IGNM Route**

Source: ENTSOG

The final investment decision is expected in December 2020. The project will be implemented after the signing of a cooperation agreement with MER (state-owned company for the exploitation of North Macedonia's energy resources), which will include the stages that must be followed by both sides for the implementation of the interconnection as well as the details of each side's obligations and responsibilities. The project is at the stage of completion of basic planning, while the environmental terms have already been approved.On February 6, 2020, Greece's Energy Ministry approved the environmental terms for the construction and operation of the project "High Pressure Gas Pipeline Nea Mesimvria - Eidomeni". In this decision, DESFA was named as the entity undertaking the proposed project. According to the approved ESFA Development Plan 2017-2026, the above decision covers one out of three terms linked to approving inclusion of the project in the Development Plan.

The other two concern the commitment of gas transport by users (requires the conduct of a market test by DESFA) and the decision about financing the project.

Ionian - Adriatic Pipeline (IAP)

The Ionian Adriatic Pipeline (IAP) is a proposed pipeline to supply gas in SE Europe. It begins in Albania and passes through Montenegro, Bosnia and Herzegovina and Croatia. In Albania, it will be connected to the TAP pipeline.

Map 5.33 **IAP Route**

Source: TAP AG

The project is currently at the stage of preliminary planning[14] (Croatia - Montenegro - Albania), while the construction licence procedure is in progress in Croatia and Albania.

Turkish Stream Pipeline

The Turkish Stream pipeline is a gas pipeline connecting Russia with Turkey across the Black Sea. On January 18, 2020, the opening ceremony was held, marking the first deliveries of natural gas to Turkey via the new Turkish Stream pipeline. On January 27, 2020[15], 1 bcm of natural gas was delivered via the pipeline.

Map 5.34 **Turkish Stream Route**

Source: Gazprom

[14] Energy Community (2020), "Ionian Adriatic Pipeline", https://energy-community.org/regionalinitiatives/infrastructure/PLIMA/Gas16.html

[15] Gazprom (2020), "First billion cubic meters of gas supplied via TurkStream", https://www.gazprom.com/press/news/2020/january/article498525/

In addition, according to an announcement by Bulgartransgaz, Russian gas for Bulgaria, Greece and North Macedonia is now delivered via the new entry point (on the Bulgaria - Turkey border). In practice, this means that as of early January 2020 Gazprom, by delivering gas via the Turkish Stream pipeline, replaced the route that passed through Ukraine and Romania via the Trans Balkan Pipeline. At the same time, new conditions are now in place for access to the LNG terminal at Revithoussa and to the Alexandroupolis FSRU.

The East Med Pipeline

This project was conceived by DEPA-Edison in 2011 and has been promoted by the above companies. The East Med pipeline is now included in the latest PCI list of October 30, 2019. On January 2, 2020, an Intergovernmental Agreement between Greece - Cyprus - Israel was signed in Athens for the implementation of the aforementioned project. Italy, which was absent in the ceremony, through the Italian Minister for Economic Development, Mr. Patuanelli, sent a letter to the Greek Minister for Environment and Energy, according to which Italy supports the project in the context of the European PCIs

Map 5.35 **East Med Pipeline Route**

Source: IGI Poseidon

On January 2, 2020, Energean and DEPA signed a Letter of Intent for the sale and purchase of 2 bcm of natural gas per year (corresponding to 20% of the pipeline's initial capacity) from Energean's fields (Karish and Tanin, via the FPSO "Energean Power") in Israel's Exclusive Economic Zone.

Further details, including terms, points of sale, the composition of the natural gas, the charterer, etc., will be agreed and included in the Gas Sales Purchase Agreement [16](GSPA).

On March 3, 2020, a Joint Ministerial Decision was issued approving the commencement of the licencing procedure for the East Med pipeline and especially for the Greek onshore section of the pipeline. The licencing procedure is expected to be completed by the fourth quarter of 2021, so that the implementation of the East Med pipeline can begin then, while it is expected to be completed in 2024. On April 29, 2020, YAFA Poseidon issued a call for the preliminary contruction activities for the East Med pipeline, with a total cost of €2.4 billion before tax and €2.97 billion after tax. More specifically, the activities concern the detailed engineering design, procurement, construction, transport, installation and pre-commissioning (EPCI) of the pipeline's offshore sections. This call for tenders concerns the first stage of the East Med pipeline, which is planned to transport 10 bcm/year plus 1 bcm for Cyprus, will end on June 20, and will be completed with the selection of two contractors.

The design and development of the first stage takes into account all research and development activities, including the related pre-investment, on the basis of a possible increase of the pipeline's capacity to 20 bcm/year at a later stage. The draft law for the Intergovernmental Agreement on the East Med pipeline was submitted to Parliament on May 4, 2020, after the licencing process for the project had commenced in Greece and a call for tenders had been issued for the main parts of the final feasibility study prepared by the entity undertaking the project, YAFA Poseidon. The Intergovernmental Agreement for the construction of the pipeline was ratified by the Greek Parliament on May 14, 2020.

The next steps of the project involve the completion of the feasibility study, amounting to approx. €70 million, and the taking of

[16] Energean (2020), "Energean and DEPA agreement paves the way for commercial operation of East Med pipeline", Joint Press Release, https://www.energean.com/media/3629/20100202-energean-depa-loi.pdf
[17] Satras, N. (2019), "DIORYGA GAS FSRU Project - part of European Natural Gas Grid", RAE Day Conference (84th TIF), http://www.rae.gr/site/file/categories_new/about_rae/factsheets/2019/gen/16092019?p=file&i=4

the final investment decision (FID). Taking also into account the data in the studies mentioned above, the greatest obstacles for the implementation of the project remain the following:

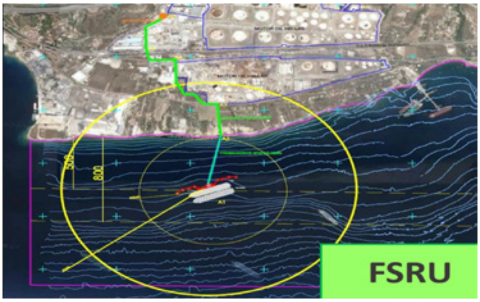
- ensuring sufficient quantities of natural gas for exports
- achieving competitive prices
- concluding a series of sale agreements with European customers

In addition, the technical challenges of the project will have to be met, especially the great depths at which certain subsea sections of the pipeline are planned. Given the current and future demand for natural gas in Europe, the potential contribution of the East Med pipeline in covering gas supply requirements will not exceed 3%, at best.

Dioryga Gas FSRU

This project (proposed and promoted by the Motor Oil Hellas group [17]) consists of a Floating Storage Regasification Unit to be anchored at a distance of 1.5 km south-west of Motor Oil's refinery in Agioi Theodoroi near Corinth. The project, which obtained an ASFA licence from RAE in early March 2019, will be connected to ESFA via an offshore and onshore pipeline. The planned storage capacity of the unit is 135,000 to 170,000 m3, with maximum regasification capacity of 470,000 ncm/h or an annual capacity of 2.6 bcm. The project will strengthen security of gas supply at national and European level, will constitute a new ESFA entry point, and, upon the required interconnections of ESFA with neighbouring gas systems, will obtain access to the countries of SE Europe.

Map 5.36 **Dioryga Gas FSRU**



Source: Motor Oil Hellas

It will also create benefits for the end consumer, since it will provide additional liquidity to the LNG market (lower procurement prices) and contribute to the decongestion of the LNG terminal at Revithoussa, of which the first indications emerged in the last quarter of 2019 and upon drafting the Final Annual LNG Unloading Plan for 2020 by DESFA . Lastly, the project may operate auxiliarily:

- with the LNG terminal at Revithoussa (proximity - double unloadings);
- with the 2020-2024 5-year Development Plan for the natural gas distribution network of DEDA (Public Gas Distribution Network), which provides LNG supply to the cities of Patras, Agrinio and Pyrgos;
- with activities in the emerging Marine LNG & Small-Scale LNG market.

ELECTRICITY

In Greece, the electricity market operated until recently on the basis of a pool structure, meaning that the total available power formed a "pool" from which participants in the distribution network drew the electricity they supply to their customers - consumers.In recent years, there has been an ongoing effort to exploit RES potential, with the aim of meeting the country's commitment for higher RES penetration into the Greek energy system, but also for exploiting domestic resources towards safeguarding energy supply. Emphasis is given to high commercial maturity technologies that exploit domestic potential (e.g. wind farms, solar PV parks, biomass, small hydro), which have attracted high investor interest. It is worth noting that gas and RES units have started replacing a large segment of lignite production, leading to a considerable increase in total installed capacity for power generation in the last decade thanks to the RES.

(a) Electricity Supply and Demand

Historically, lignite has played a significant role in Greece's power generation and covered almost 20% of total electricity demand in the interconnected – except of the islands - system

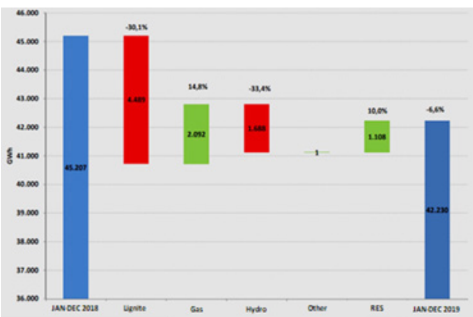
[18] Liaggou, Ch. (2019), "Οξύνεται ο ανταγωνισμός εγχώριων ομίλων στην αγορά φυσικού αερίου", https://www.kathimerini.gr/1052415/article/oikonomia/epixeirhseis/o3ynetai-o-antagwnismos-egxwriwn-omilwn-sthn-agora-fysikoy-aerioy

in 2019 and much higher share (more than 60%) in previous years. However, its dominance has been reduced in the last decade due to the fall in electricity consumption and the increased penetration of RES for power generation - mainly wind and solar - and natural gas. RES covered almost one third of the total domestic electricity demand over the three-year period 2017-2019.

Power Generation

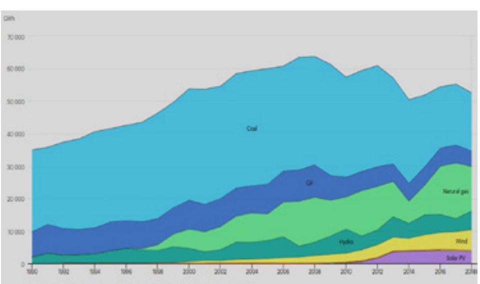
In 2019, Greece produced 42.2 TWh of electricity in the interconnected system, down 6.6% from levels in 2018. Natural gas was the largest source of energy in domestic power generation, accounting for 16.2 TWh in 2019, followed by RES, which increased their share from 11.1 TWh in 2018 to 12.2 TWh in 2019. The contribution of lignite in power generation has declined considerably over the last two years, from 14.9 TWh in 2018 to 10.4 TWh in 2019.

Figure 5.112 **Change in Power Generation (GWh) in the Greek Interconnected System, 2018-2019**



Source: IPTO[19]

Figure 5.113 **Power Generation by Type of Fuel, 1990-2018**

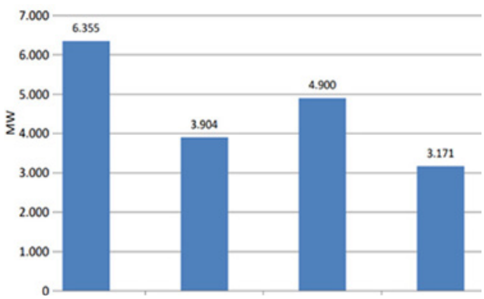


Source: IEA (2020)

Installed Capacity

In 2019, the total installed capacity of power generation units in the Greek interconnected system amounted to 18.3 GW, up 5.2% from levels in 2018 (17.4 GW). RES were the only power generation source that increased its share in domestic installed capacity in the interconnected system in 2019 as compared to 2018, with new installed capacity of 886 MW and total installed capacity at 6.3 GW. In 2019, the total installed capacity of lignite, hydro and gas units remained at the same levels as in 2018, as shown in Figure 5.114.

Figure 5.114 **Total Installed Capacity of Units by Type of Fuel in the Greek Interconnected System, 2019**



Source: Hellenic Energy Exchange

Electricity Imports and Exports

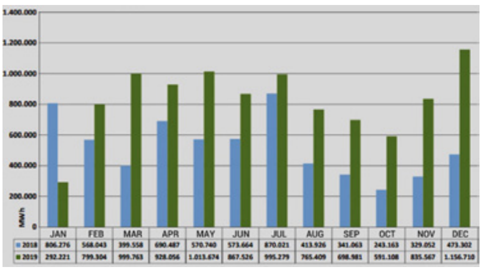
Greece is well connected to neighbouring countries and apart from the domestic electricity production is increasingly becoming active in power tading activities. However, the interconnection index[20] of the country's power grid is at 9%, i.e. at levels lower than in other power systems in SE Europe as the interconnection indices in Bulgaria and Rumania are at 12% and 11% respectively. Electricity imports increased due to new interconnections, though they vary considerably from year to year.

More specifically, electricity imports into Greece amounted to 9.6 TWh in 2019, mainly from Bulgaria, Italy and North Macedonia. Electricity exports amounted to 2.9 TWh in the same year, mainly routed to Italy, Albania and North Macedonia. Greece has been a net importer of electricity for many years, with total net imports in 2019 at approx. 6.7 TWh,

[19] http://www.admie.gr/fileadmin/groups/EDRETH/Monthly_Energy_Reports/Energy_Report_201912_v1.pdf
[20] Defined as the ratio of the import capacity of existing interconnections to the installed power generation capacity of the system each time.

covering approx. 13% of the country's needs, based on IPTO's data. It is worth noting that a second electricity interconnection between Bulgaria and Greece is under development and is expected to become operational by 2023. This project is of great importance for the market coupling of both countries, and is expected to increase considerably the interconnectivity of Greece and bring the country closer to the minimum European target of 15% by 2030.

Figure 5.115 **Electricity Balance (MWh) at the Interconnections of Greece, 2018-2019**



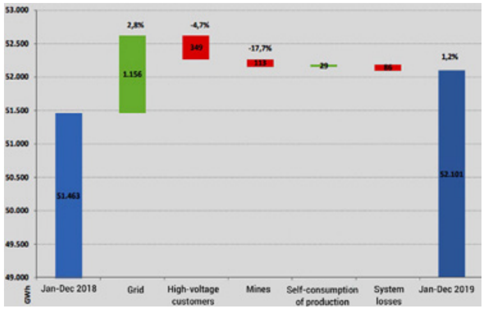
Note: The electricity balance at the interconnections is calculated as the difference ("Actual Import Flows" - "Actual Export Flows") for all interconnections.
Source: IPTO

Electricity Consumption

Electricity consumption in Greece increased steadily up to the peak of 58.8 TWh in 2008; followed by a 5-year period of decline, from 2009 to 2013, as a result of the prolonged financial crisis. The electricity consumption has recovered slightly in recent years, and in 2019 Greece consumed 52.1 TWh (see Figure 5.116) in the interconnected system (except of the islands, with 5.6 TWh).

Based on IEA data, the residential sector consumed the majority of electricity, accounting for 36% of total final electricity consumption in 2017, followed by the commercial (35.6%) and the industrial (22.7%) sectors. Other sectors (i.e. agriculture and transport) accounted for a smaller share of total final electricity consumption.

Figure 5.116 **Change in the Electricity Demand (GWh) in the Interconnected System of Greece, 2018-2019**



Source: IPTO

Non-Interconnected Islands

In Greece (mainly in the Aegean Sea), most islands currently obtain electricity from autonomous power generation plants, operating with diesel and fuel oil, and RES units (wind and photovoltaic). These islands have not yet been interconnected with the mainland grid, mainly due to technical and financial difficulties, since interconnections are capital-intensive projects. The electricity market of the Non-Interconnected Islands (NII) now consists of 29 autonomous systems, since Paros and Syros were interconnected in May 2018 and Mykonos in May 2019. Some of these systems comprise several islands (island clusters), and the operation and management of the NII market is undertaken by the Hellenic Electricity Distribution Network Operator (HEDNO) and more specifically by its Island Management Division. According to RAE data[21], peak demand varies among the 29 autonomous island clusters:

- peak demand in 19 "small" autonomous systems is up to 10 MW;
- peak demand in 8 "medium-sized" autonomous systems fluctuates from 10 MW to 100 MW; and
- peak demand in 2 "large" autonomous systems, namely Crete and Rhodes, is over 100 MW.

Electricity consumption in the NII varies correspondingly, from a few hundred MWh in the smaller islands (e.g. Antikythira, Agathonisi, etc.) to some TWh in the largest NII (Crete).

[21] http://www.rae.gr/site/categories_new/electricity/market/mdn.csp

As mentioned above, the NII are usually equipped with units that use diesel as fuel and are expensive, environment-unfriendly, and cannot benefit from the advantage of economies of scale. However, the NII feature excellent conditions for wind and solar energy utilisation.The operation of these types of energy in the islands is complicated by their variability and the need for back-up systems. Based on data provided by the HEDNO's Island Management Division, the total installed capacity of power generation units in the NII was approx. 2.2 GW in 2019, of which 79% concerned thermal stations (see Table 5.115), increased by 7.4% compared to 2018 levels (2,070.10 MW).

Table 5.115 **Installed Capacity (MW) of Power Generation Units on NII, 2019**

Categories	Installed Capacity (MW)	Percentage (%)
Thermal Stations*	1,756.97	79.0%
Wind Parks	306.15	13.8%
Photovoltaic**	129.75	5.8%

Hydro	0.3	0.0%
Total	**2,224.26**	**100.0%**

*Last available data is for 2018; **Installed capacity of Special Program P/V and net metering is not taken into account. Source: HEDNO

Similarly, power generation in the NII was at approx. 5.6 TWh in 2019, of which 83% concerned thermal stations (see Table 5.116), recording a very slight drop in the range of 0.3% as compared to levels in 2018 (5,572 GWh).

Table 5.116 **Power Generation (MWh) in NII, 2019**

Categories	Power Generation (MW)	Percentage (%)
Thermal Stations	4,594,664.4	82.7%

(b) Planned New Projects

Of great significance are the developments regarding the electricity interconnections of the islands with the power grid in mainland Greece, and improved cross-border interconnections that will enable the national electricity transmission system to cover the requirements of the new targets for RES penetration and the incorporation of energy storage systems by 2030.

Indicatively, Greece's power grid operator IPTO has already announced the inclusion in its ten-year plan for the years 2021-2030 of the electricity interconnection of the North Aegean islands, to be realised at the same time as the interconnection of the Dodecanese. With regard to the country's international interconnections, IPTO's ten-year plan includes the construction of the second interconnector between the Greek and Bulgarian power systems, an upgrade of existing lines, and the development of new interconnections with the neighbouring systems of North Macedonia and Turkey. As already analysed, Greece has electricity interconnections to Albania, North Macedonia, Bulgaria, Turkey and Italy through a 400KV connection. IPTO is now taking initiatives to upgrade Greece's interconnections with neighboring countries, acknowledging transboundary grid link insufficiencies are having a negative impact whose consequences include market functional disorders and higher electricity prices.

The operator has formed working groups with all of Greece's neighboring countries to examine the prospect of constructing or reinforcing existing interconnections. These associations include cooperation with Italian operator Terna. The two sides, prepared to consider both an upgrade of the existing system or the development of a new one, estimate that the Greek-Italian grid interconnection requires a capacity increase of between 500 and 1,000 MW. IPTO and Terna have agreed to proceed with related studies for an optimal solution as soon as possible. The operators intend to reach a decision within the next few months. Any selection will need to be approved by the Greek and Italian regulatory authorities of energy.

The existing Greek-Italian electricity grid interconnection, a 163 km subsea cable with a 500 MW capacity in operation since 2002, was used to facilitate the Target Model's next stage, market coupling, beginning on December 15, 2020, with the aim of harmonizing the energy markets of the two countries. Regarding Crete's electricity interconnections, IPTO has left unchanged its completion target for the Crete-Attica grid interconnection, keeping it at June, 2023, in its new 10-year development plan covering 2022 to 2031[22], an update on the 2021-2030 plan delivered last March. The Crete-Attica interconnection is a landmark project in Greece. It is the largest energy project under construction and the second largest overall and it will contribute significantly in the process for economic recovery with a special positive sign for the economy of Crete, one of the most important economic regions in Greece.

Preliminary work on the aforementioned project began last summer, while significant steps have been made for the project's environmental licensing requirements, a procedure expected to be completed by the end of 2021. Expropriation procedures, including property purchases, needed for the installation of converter stations and overhead cables, are also anticipated to have been completed by the end of this year. Sound progress has been reported along this front.

In July 2020, the subsidiary of IPTO "Ariadne Interconnection" and Eurobank announced the signing of a loan agreement up to €400 million to finance the project of "Crete-Attica electrical interconnection" with a total budget of €1 billion. The common bond loan has a repayment period of ten (10) years with a possibility of partial withdrawals according to the implementation course of the interconnection. In addition to bank lending, the project will be implemented using equity of €200 million, while the co-finance of Greece and the European Union under the operational program "Competitiveness, Entrepreneurship, Innovation 2014-2020" or/ and its following program, will be used for the remaining €400 million.

A small-scale grid interconnection to link Crete with the Peloponnese is scheduled for completion at the end of March 2021, according to IPTO's updated ten-year development plan. According to IPTO, Crete's grid interconnection with the mainland will require the development of a new, upgraded regional energy control center on the island. The new center will be needed to ensure effective management of new energy market data, not achievable through the existing center's means and infrastructure, as these would not be able to incorporate new technologies. Also, the existing energy control center's maintenance has become extremely difficult and costly due to the unavailability of spare parts and experienced technicians for its type of technologies.

SOLID FUELS

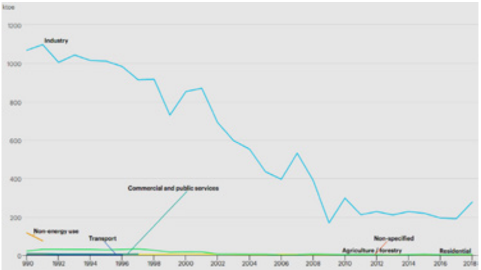
(a) Supply and Consumption

Historically, lignite has played a significant role in Greece's power generation and covered almost 20% of total electricity demand in the interconnected – except of the islands - system in 2019 and much higher share (more than 60%) in previous years. However, its dominance has been reduced in the last decade due to the fall in electricity consumption and the increased penetration of RES for power generation - mainly wind and solar - and natural gas. The contribution of lignite in power generation has declined considerably over the last two years, from 14.9 TWh in 2018 to 10.4 TWh in 2019.

In Greece, lignite accounted for 28.57% of total primary energy supply in 2009 and 14.85% in 2019, the third largest share after oil and natural gas. Lignite is Greece's only significant fossil fuel resource. Based on IEA's data, final lignite consumption in Greece stood at 6 ktoe in 2018.

[22] https://www.admie.gr/sites/default/files/nea-anakoinoseis/30-12-2020/%CE%A0%CF%81%CE%BF%CE%BA%CE%B1%CF%84%CE%B1%CF%81%CE%BA%CF%84%CE%B9%CE%BA%CF%8C%20%CE%A3%CF%87%CE%AD%CE%B4%CE%B9%CE%BF%20%CE%94%CE%A0%CE%91%202022-2031%20-%20%CE%9A%CF%8D%CF%81%CE%B9%CE%BF%20%CE%A4%CE%B5%CF%8D%CF%87%CE%BF%CF%82.pdf (in Greek)

Figure 5.117 **Final Lignite Consumption by Sector in Greece, 1990-2018**



Source: IEA (2020)

(b) Local Exploration and Production

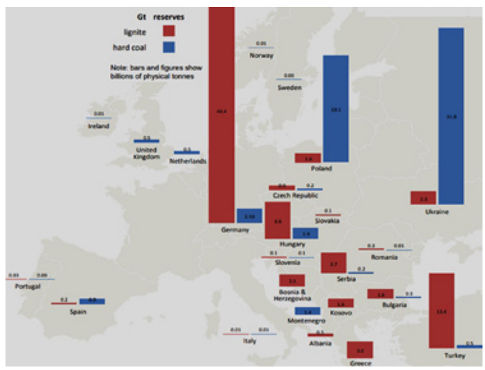
Based on data from the European Association for Coal and Lignite (EURACOAL)[23], lignite production in Greece amounted to 27.3 million tonnes in 2019. Based on IPTO's data, electricity produced from lignite declined considerably from 14.9 TWh in 2018 to 10.4 TWh in 2019, due to the increase in RES, lower total demand for electricity, and the high cost of emission rights, which makes power generation from lignite uneconomic.

Imported hard coal (approx. 0.4 million tonnes), almost all from Russia, is used in the cement industry.Total confirmed geological reserves of lignite in Greece amount to approx. 5 billion tonnes. These deposits are geographically dispersed across Greek territory[24]. Based on current technical-economic conditions, the deposits that are suitable for energy exploitation amount to approx. 3.2 billion tonnes and are equivalent to 450 million tonnes of oil. The main exploitable deposits are in the regions of Ptolemais, Amyntaio and Florina, with reserves estimated at 1.8 billion tonnes, in the area of Drama, with reserves of 900 million tonnes, and in the area of Elassona with 169 million tonnes.

There is also a lignite field with reserves of approx. 223 million tonnes in the area of Megalopolis, in the Peloponnese. Based on total exploitable lignite reserves in the country and the expected rate of consumption in future, it is estimated that these reserves are sufficient for more than 45 years. Up to now, mined quantities of lignite amount to 29% of total reserves. In addition to lignite, Greece has a large deposit of peat in the area of Philippi (eastern Macedonia). Exploitable reserves at this deposit are estimated at 4 billion cubic metres and are equivalent to approx. 125 million tonnes of oil.

In general, the quality of the Greek lignite is low. Thermogenic power is in the range of 975-1,380 kcal/kg in the areas of Megalopolis, Amyntaio and Drama, 1,261-1,615 kcal/kg in the Ptolemais area, and 1,927-2,257 kcal/kg in the areas of Philippi and Elassona. An important comparative advantage of lignite in Greece is the low sulphur content.

Map 5.37 **Exploitable Lignite Reserves in Europe**



Source: EURACOAL

Greece to Phase Out Lignite

According to the updated NECP of December 2019, all PPC's lignite-fired power plants are expected to be phased out by late 2023 (apart from the new one, Ptolemais 5, currently under construction, which is expected to be phased out in 2028), with a total capacity of approx. 4 GW, and all lignite mines in the regions of western Macedonia and Megalopolis are set to be closed.

The fuel that drove the country's electrification is gradually being phased out, in line with EU policy and the country's commitments. The first PPC's lignite units (i.e. Amyntaio and Kardia) were closed in 2020 and a Master Plan for the way ahead is now ready. The Master Plan includes strong tax and development

[23] EURACOAL (2020), "Market Report 2020 no. 1"
[24] https://www.dei.gr/el/oruxeia/apothemata-kai-poiotita

incentives and emphasis on manufacturing, tourism and green energy, to ensure a smooth transition to the post-lignite era for the regions of western Macedonia and Megalopolis.

In February 2020, the Inter-Ministerial Committee responsible for the lignite phase-out appointed Mr. Kostis Mousouroulis, a senior official of the European Commission, as Coordinator of the Just Transition Development Plan (SDAM) for the regions of western Macedonia and Megalopolis. More specifically, the Ministerial Council Act states that Mr. Mousouroulis will be the Chairman of the Coordination Committee, i.e. the Working Group, which, under the supervision of Inter-Ministerial Committee, will draw up and implement the Just Transition Plan and will coordinate the activities related thereto, starting in 2020. It is worth noting that IENE recently completed a special Report[25] on behalf of the SDAM Coordination Committee about the current situation and the prospects of regions in energy transition in Greece.

The proper transition of lignite regions into an era of clean energy, development and business growth requires financing in several sectors. What is sought is financial assistance for infrastructure projects and support for fast-track investments in RES, energy efficiency and electromobility, projects to support and strengthen the primary sector, and other projects that promote innovation and competitiveness.

Attaining these aims will require full and productive utilisation of all available financing means and sources for the transition into the post-lignite era. In particular, the investments under consideration will enable full utilisation of the resources of the three pillars of the Just Transition Mechanism (Just Transition Fund, Special InvestEU status, Public Sector Credit Facilities), while also advancing the financing of investments via the other sources, by mobilising considerable private capital (leverage).

Table 5.117 **Timeframe for Shutting Down Lignite-fired Plants in Greece**

Lignite-fired plant	Rated capacity	Year of shutdown
Kardia 1	275	2019
Kardia 2	275	2019
Kardia 3	280	2021
Kardia 4	280	2021
Agios Dimitrios 1	274	2022
Agios Dimitrios 2	274	2022
Agios Dimitrios 3	283	2022
Agios Dimitrios 4	283	2022
Agios Dimitrios 5	342	2023
Amyntaio 1	273	2020
Amyntaio 2	273	2020
Florina/Meliti	289	2023
Megalopolis 3	255	2022
Megalopolis 4	256	2023

Source: IEA (2020)

In this context, initiatives are being planned and developed to utilise all financing means and tools. At this point, it is worth noting that the aim is fast-track implementation of the investments, with a considerable part thereof being realised in 2022 and 2023. The total time allocation of the investment cost will depend on several parameters, such as approval of the incentives by the European Commission, land restoration, public investments and other supportive programs and projects, simplification of licencing procedures, etc. Prompt finalisation of the incentives will be significant for the unimpeded and timely implementation of the investment plans. At the same time, land restoration works impact directly the timing of the investments, due to both the financing costs they involve and the fact that they constitute a precondition for implementing some of the investments.

In addition, the realisation of public investments, especially on the level of infrastructure, will increase considerably the attractiveness of the areas and the capability to accommodate new investment plans, while the maturity of the project's studies in conjunction with the completion of Special Urban Planning and the acceleration of the licencing procedures will contribute decisively to fast-track implementation of the financing plan.

[25] IENE (2020), "Current Situation and Prospects for Areas in Energy Transition in Greece", IENE Study (M58)

It is worth noting that taking into consideration the investment plan as envisaged at this stage, which will obviously be enriched with new investments over time, the total capital cost of foreseen investments (which are initially estimated at more than €5 billion), the parameters of each financing source and the need to adopt the best possible financing scheme, the initial plan for the financing has as follows:

- 10% subsidies, by turning to account the first pillar of the Mechanism (Just Transition Fund)
- 30% loans on favourable terms, by using the other two pillars (Special InvestEU status, Public Sector Credit Facilities) and other financing tools
- 40% commercial loans, by drawing financing from domestic and international credit institutions
- 20% equity capital, by mobilising and attracting the private capital of candidate investors.

This financing scheme indicates that a considerable part of the investments will be realised through leverage of commercial (bank) loans and equity capital, since important investments that are already mature do not require further support.

In parallel, utilising the Just Transition Mechanism, not with the aim of exhausting immediately the subsidies (Just Transition Fund) but rather by making the fullest possible use of all three pillars, will allow the incorporation and implementation of an increasing number of investments. Indicatively, in July 2020, the state's Green Fund approved the first two calls for submitting proposals for financing "green" actions, with beneficiaries being the lignite-dependent municipalities of Amyntaio, Florina, Eordaia, Kozani and Megalopolis. The first call concerns the submission of Action Plans for Energy and the Climate and the second call concerns the financing of interventions for promoting the cyclical economy, with positive social and environmental impact, in the context of the National Strategy for the Cyclical Economy.

In August 2020, the Green Fund approved the third successive call for submitting proposals for financing "green" actions, in the context of its first-ever program for phasing out lignite. The call aims at the preparation of the related studies and planning and licencing procedures for the comprehensive management system for the pilot program of cyclical liquid waste management in these areas. The beneficiaries of the Program include the Region of western Macedonia and all First-Degree Local Authorities in the Kozani and Florina Regional Units. The total budget made available with this Call amounts to €1 million, with a minimum budget of €100,000 for each proposal. The ultimate goal is to promote a comprehensive model for the cyclical management of urban waste from towns and villages in the Kozani and Florina Regional Units of the western Macedonia Region. More specifically, there will be support for developing comprehensive systems for urban waste management, so that the waste sludge produced is processed towards converting it into an environment-friendly renewable fuel and/or a secondary material that is useful and safe for humans and the environment.

(c) Planned New Projects

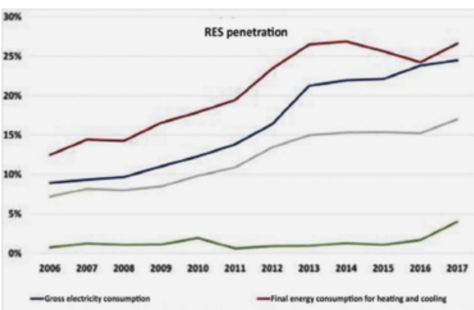
There is no planned new coal/lignite project in Greece. Ptolemaida V is the only lignite-fired power plant, operated by PPC, which is currently under construction. The plant, expected to be completed in 2022, is initially planned to operate as a lignite-fired power station for a six-year period before switching to another fuel or fuels. All options are being left open, meaning that, beyond 2028, Ptolemaida V could run on gas, biomass, waste-to-energy or a combination of these energy sources. Japan's Mitsubishi, providing the new facility's electromechanical equipment, was commissioned, some time ago, to conduct a study determining the optimal choice of fuel for Ptolemaida V beyond 2028. Continued use of lignite, after 2028, at Ptolemaida V has also been tabled as a possibility if carbon capture, utilization and storage (CCUS) technology is applied for a zero net carbon footprint.

RENEWABLES

(a) Overview of Sector's Development

The contribution of RES in energy consumption in Greece has shown a significant increase over the period 2006-2017, as their overall contribution in 2017 as a share of gross final energy consumption amounted to 17%, more than doubling the corresponding share in 2006 (see Figure 5.118), based on NECP's data. Apart from the transport sector, in which the share of RES recorded marginal variations and a stable increase only in 2016 and 2017, the contribution of RES in both gross electricity consumption and final energy consumption for heating in the period 2006-2016 increased considerably, at an average annual rate near 10%. It is worth noting that the variations observed in different periods in the share of RES in final energy consumption for heating are exclusively due to the use of solid biomass, which has fluctuated over recent years, following its sharp increase in the early 2010s and its peak in 2012.

Figure 5.118 **Total and Specific Shares of RES in the Greek Energy System on the Basis of EU Methodology, 2006-2017**



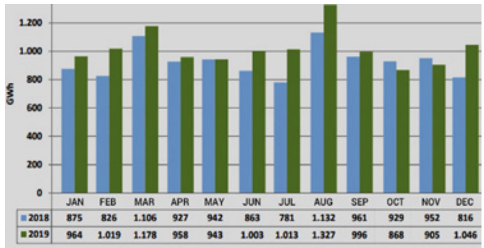
Source: NECP

Based on NECP's data, the share of RES in domestic gross electricity consumption in 2017 was 24.5%, a marked increase as compared to 2006, when the respective share was in the range of 9%. More specifically, regarding power generation from RES with non-controllable production features, i.e. power generation from photovoltaic and wind units, the percentage already amounts to over 15% in gross final electricity consumption.

Power Generation from RES

In Greece, power generation from RES in the interconnected system amounted to 12.2 TWh in 2019, up from 11.1 TWh in 2018, as a result of the fast growth of the installed capacity of wind and solar and the reduction in total electricity supply over the last decade.

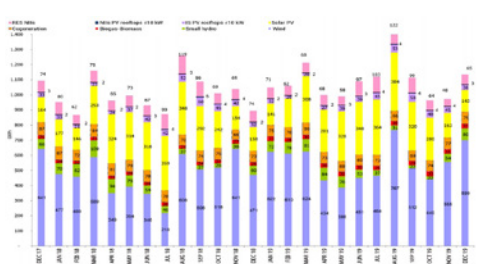
Figure 5.119 **Power Generation from RES in Greece, 2018-2019**



Source: IPTO

Total power generation in Greece from wind forms interconnected to the system amounted to approx. 6.6 TWh in 2019, and from small hydro units and biogas-biomass stood at 690 GWh and 362 GWh respectively. In addition, the total power generation from cogeneration units and assigned cogeneration interconnected system units stood at 186 GWh and 876 GWh respectively. The electricity generation from solar PV units in the interconnected system was almost 3.2 GWh in 2019 (see Figure 5.120).

Figure 5.120 **Power Generation of RES and Cogeneration (GWh) Units and Rooftop Photovoltaic Power Stations ≤10 kW, 2017-2019**



Source: LAGIE (Hellenic Electricity Market Operator)

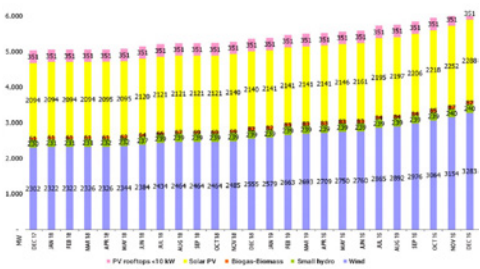
Greece has significant RES potential, which can contribute substantially to an environment-compatible restructuring of its energy system.

This potential mainly comprises solar, wind, hydro and geothermal energy as well as biomass. The ample wind potential is mainly found in the country's island regions (e.g. Crete, Aegean Sea, Evia, etc.), where most wind farms are currently located. The exploitation of Greece's wind potential, in conjunction with improvements in the technologies used in state-of-the-art wind turbines, is expected to contribute significantly towards sustainability.

Installed Capacity from RES

Based on data from the bulletin of the Renewable Energy Sources Operator & Guarantees of Origin (DAPEEP) of December 2019[26], the total installed capacity of RES units operating in the Greek interconnected system and of rooftop photovoltaic units smaller than 10 kW amounted to 6,249 MW in 2019 (see Figure 5.121), of which the majority is based on wind (52.5%) and photovoltaic (36.6%) units.

Figure 5.121 **Installed Capacity (MW) of RES Units Operating in the Greek Interconnected System and Rooftop Photovoltaic Units ≤10 kW, 2017-2019**



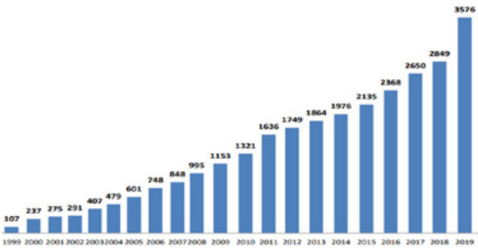
Source: LAGIE

During 2005-2019, the installed capacity of onshore wind farms increased almost six-fold, and more than 2.9 GW of new power capacity were added to existing plants in Greece (see Figure 5.122).

2019 - A Record Year for Wind Energy in Greece

2019 was a record year for wind energy in Greece, since 727 MW of new wind farms were connected to the network, almost four times the annual average during the previous decade (185 MW). In addition, the largest wind farm complex, with a capacity of 154.1 MW, was connected in South Evia (Kafireas) by Enel Green Power.

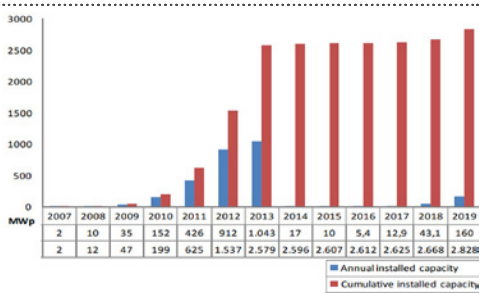
Figure 5.122 **Installed Capacity (MW) of Onshore Wind in Greece, 1999-2019**



Source: Hellenic Wind Energy Association

It is worth noting that the sharp increase of solar PV projects in Greece during the period 2011-2013 was due to the greater financial incentives for these type of investments. However, this short-lived increase resulted in a long-term and substantial rise in consumers' electricity bills, due to higher special taxes for RES levied on consumers. The entities shaping energy policy in Greece were concerned about this development and reacted by blocking new solar PV projects, even if they required only a small percentage of compensation compared to past projects. In 2019, the domestic solar PV market showed the first substantial indications of recovery, and the trend is towards an imminent return to figures in the range of hundreds of MW annually. In the past year, autoproduction systems increased by 3.1% compared to 2018, still at levels considerably lower than the country's potential. For another year, the solar PV market covered approx. 7% of Greece's electricity needs, placing the country in the fourth position globally (after Honduras, Italy and Germany) regarding the contribution of solar PV in total electricity demand.

Figure 5.123 **Installed Capacity (MW) of Photovoltaics in Greece, 2007-2019**



Source: HELAPCO

[26] http://www.lagie.gr/fileadmin/groups/EDRETH/RES/20200326_DELTIO_APE_DECEMBER.pdf

Table 5.118 **New Installed Capacity (MW) of Photovoltaics in Greece, 2019**

New installations that interconnected within 2019	Number of systems	Power (MWp)
Solar PV parks	246	150,29
Net Metering	362	9,57
Special Solar PV programme (expired 31.12.2019)	17	0,16
Total	625	160,02

Source: HELAPCO

Net-metering is one of the tools for promoting autogeneration and autoconsumption using RES. Net-metering allows the consumer to cover a substantial part of his autoconsumption, while also providing him with the capability to use the network for indirect storage of the green energy. However, the number of autoproduction projects remains small compared to the country's potential: the number of net-metering units was 362 in 2019, with a total installed capacity of 9.57 MW, while only approx. 10% of autoproduction systems has been installed in the residential sector, by the criterion of installed MW.

RES in Non-Interconnected Islands (NII)

As discussed earlier, there are currently in operation 29 autonomous island systems in Greece. In these NII, there must be a special focus on using RES for power generation, since there is high potential for their use and they are economically advantageous, since in most NNI both the final average power generation costs and the corresponding variable costs of oil use are very high. In addition, the European Directive 2015/2193/EU has come into force for limiting emissions of pollutants from medium-sized combustion plants for power generation, which will ultimately lead to their elimination from the NII.

However, the penetration of RES generation is subject to specific limitations, which are mainly determined by the technical minima of installed thermal units and the maximum permissible hourly penetration of non-controllable RES on the basis of load.

Total RES penetration in the NII is currently close to 21% of power generation, though without capability for further substantial penetration if the above limitations are not addressed, mainly through the application of innovative management technologies, utilising the technology of modern-day RES units with power electronics and/or with the installation and operation of storage systems. However, as a first step, HEDNO is in the process of readjusting its planning for developing state-of-the-art NII electricity systems, with higher RES penetration, modernisation and digitalisation of its infrastructure in the 29 non-interconnected island systems[27].

A special case are the many uninhabited islands and islets in Greek territory, which have very high wind potential and where wind and solar PV parks could be installed.

The promotion of the use of hybrid stations with RES, i.e. RES and storage, is another solution in cases where the electricity interconnection of the islands is not economically viable, but such stations will have to be assessed as to technical-economic factors and compared to the existing situation, and their installation and operation can be promoted only if it is ensured that power generation costs are reduced in total in the autonomous system involved each time and as compared to other mature solutions. Research concerning the operation of such stations at pilot application is necessary, and already several such projects are at an advanced stage of development. However, the framework for their support must be planned so that no stranded assets are created, demanding further support and subsidies from outside the electricity market, while the possibility of future interconnection of each island with the mainland grid and the impact on the operation and operational reinforcement of hybrid stations must also be taken into consideration. One parameter that will have to be taken into account in the country's energy planning is the ad-hoc studies for the final solution in each island system and the update of spatial planning for the RES in NII, so that any further

[27] http://dda.gr/pfiles/a58762e2c76300cedc96984520d1bb7512b13507.pdf

penetration of RES can be promoted without obstacles and additional regulatory and licencing-related delays.

(b) Latest RES Legislation

On May 5, 2020, the Greek Parliament passed a law modernising environmental legislation and harmonising Greek law with EU Directives 2018/844/EU (amending the directives on the energy performance of buildings and energy efficiency) and 2019/692/EU (amending EU Directive 2009/73/EC concerning common rules for the internal market in natural gas). This new Law 4685/2020 (OJ A' 92/2020) contains legislative measures which will significantly amend, standardise and simplify the current licensing procedure for renewable energy power plants – particularly the procedure for obtaining a renewable energy source (RES) production licence and an environmental approval.

New RES Production Certificate

One of the most important changes introduced is the replacement of the production licence with a certificate. The Regulatory Authority for Energy (RAE) is authorised to issue these certificates, but the law provides for the possibility of a future ministerial decision delegating this authorisation to another person or authority.

Applications for issuing a certificate must be submitted via the electronic register, which will be established according to the provisions of the new law. Each year there will be three application rounds, which will take place during the first 10 days of February, June or October. The new law envisages two different application procedures and subsequently two different types of certificate: one for special projects and one for all other RES projects.

Simplified Environmental Licensing Procedure

Furthermore, the new law introduces various provisions that aim to simplify and expedite the environmental licensing procedure (including the renewal and amendment of the environmental approvals), as experience has shown that the respective deadlines envisaged in the pre-existing legal framework are seldom met. Thus, the environmental approvals will be valid for 15 years, instead of 10, on the condition that the circumstances under which they were issued remain unchanged. The deadlines for completing the environmental licensing process, with the exception of the public consultation deadlines, are significantly reduced, and certain stages of the procedure have been merged. It is also noteworthy that a request on behalf of the authorities for the submission of supplementary data by the applying project operator does not constitute a reason for the authorities to delay the evaluation of the file submitted.

(c) Planned New Projects

The aforementioned simplification of the licensing procedure for RES projects will play an important role in their deployment over the next years. Energy infrastructure also plays a key role in the high penetration of RES plants for power generation, and therefore the design and development of new projects by the operators will incorporate the projections for the penetration of new RES plants and will lay down the necessary adjustments and actions to ensure that its implementation is as seamless and efficient as possible for the functioning of the energy system.

A large increase in installed capacity will be required to make possible a higher RES share in the energy mix. Distribution networks will have to be constructed also in a generation-oriented, not just consumer-oriented, manner from now on. The operators of both the transmission systems and of the distribution network should design the networks with due account taken of future RES development, increasing geographical coverage and strengthening and modernising technologically the high and ultra-high voltage transmission systems and distribution networks, provided that there is a clear-cut regulatory framework in place which can be used to determine the growth rate of RES, the operator's obligations, the cost recovery method, etc. The networks should, therefore, be developed in a way that ensures maximum RES penetration and minimizes potential cuts in energy generation.

In this context, the best technical and cost-effective enhancement and expansion of energy infrastructure in both the transmission system and the distribution network for tackling congestion that prevents further growth of RES plants in specific areas will also be, for the following period, a core measure for the optimal integration of RES in energy networks.

Moreover, the development of new financing models to speed up the development of this infrastructure will be launched, whereas management complexity and time lags due to external factors will be limited through more effective planning and transparent consultation procedures. In the above context, energy network operators will examine the interventions planned and identify the costs required for both the required infrastructure and the balancing needs for the operation of these plants.

According to Greece's NECP, RES investments are expected to reach a total of €9 billion by 2030, not including new grid interconnection projects. The share of RES in Greece's energy mix is anticipated to reach 65.7% in 2030 from 32.6% in 2019, in terms of overall electricity production, primarily through new investments in wind and solar energy.

Installed wind energy capacity is projected to reach 7 GW in 2030 from 3.6 GW at present. This category's total is seen increasing to 4.2 GW by 2022, 5.2 GW by 2025, and 6 GW by 2027 before hitting the projected level of 7 GW in 2030. Similarly, installed solar energy capacity is seen rising to 7.7 GW from 3 GW at present. The total solar capacity is expected to reach 3.9 GW by 2022, 5.3 GW by 2025, 6.3 GW by 2027 and 7.7 GW by 2030.

ENERGY EFFICIENCY AND COGENERATION

(a) Energy Efficiency

Greece has applied a wide range of energy efficiency policies in recent years, most of which are based on adapting the requirements of the European Commission Directive on Energy Efficiency to the Greek legislation. The policy measures applied in the past did not result in substantial energy savings as envisaged initially, due to the economic and financial crisis, low public awareness, inadequate data and lack of financing.

In recent years, Greece has made substantial progress in promoting energy efficiency in buildings, which can be summarised as follows:

- The Greek Regulation for the Energy Efficiency of Buildings (KENAK), which determines the minimum energy efficiency requirements for buildings
- Designating buildings as being of almost zero energy consumption
- Introducing a system of Energy Inspections and the issue of Energy Certificates
- Planning a long-term strategy for renewing building stock
- The "Saving at Home" publicly financed program
- The energy upgrade of public buildings through specific actions, such as the first Energy Saving program for Local Authorities, etc.

Improving energy efficiency in all fields of consumption is the biggest challenge for the public policies to be implemented in the following decade. Therefore, it is an absolute and horizontal priority that should cover the entire scope and mix of policies and measures to be adopted. Energy savings achieved through improved energy efficiency have a direct impact on how energy is consumed, on the technologies used and on meeting consumer energy needs, also making a substantial contribution towards improving the competitiveness of all industrial activities.

According to the NECP, the objective is to improve energy efficiency in final energy consumption by at least 38% in relation to the foreseen evolution of final energy consumption by 2030, as estimated in 2007 in the context of the EU energy policies; thus, resulting in final energy consumption levels of not more than 16.5 Mtoe in 2030. There is also satisfactory performance in terms of the relevant evaluation indicators concerning the rate of reduction both with regard to final energy consumption for 2017 (16.8 Mtoe) and the energy savings target for 2020 (18.4 Mtoe), taking into account the increase in final energy consumption in order to reverse the impact of the economic recession of the previous years.

This rate of reduction is even higher if adjusted to primary energy consumption, in which case it stands at more than 43%. This demonstrates that the overall objective is to achieve an improvement in energy efficiency across the entire energy system, attaining a particularly high level of improvement in terms of how energy is made available for consumption, always in the most cost-effective way. An additional objective is set in respect of the cumulative amount of energy savings to be attained over the period 2021-2030 in accordance with Article 7 of Directive 2012/27/EU on energy savings obligations. According to the available final energy consumption figures, cumulative energy savings of at least 7.3 Mtoe should be achieved over the period 2021-2030. However, the objective will be re-calculated on the basis of the final energy consumption figures for the years 2016-2018. In addition, an objective is set for the annual energy renovation of a total floor area of the thermal zone of central public administration buildings equal to 5,400 square meters, representing just 3% of the total floor area.

The need to renovate the existing building stock is indisputable, as this will result in significant energy savings and in cost savings for citizens, and will also improve the comfort, safety and health conditions in the use of these buildings. To that end, it is necessary to establish a central quantitative objective for the renovation and replacement of residential buildings with new nearly zero-energy buildings, which could in aggregate amount to 12%-15% of all residential buildings by 2030. The objective is to have an average of 60,000 buildings or building units upgraded each year in terms of energy and/or replaced with new more energy-efficient ones. This particular objective will contribute significantly to the major upgrading of the ageing building stock, while at the same time providing a substantial boost to the construction industry through high added value technologies and essentially ensuring increased financial and operating benefits for households in Greece, also enabling them to cover their energy needs. Moreover, in respect of this dimension as well as other dimensions of the NECP, the aim is also to increase the use of natural gas in final consumption. More specifically, natural gas is expected to be the intermediate fuel for switching to a low GHG emissions model in all final consumption sectors, and may also lead to both improved energy efficiency and lower energy costs compared to other conventional technologies. A key aim is to achieve a higher gas share in all final consumption sectors and, essentially, to ensure that its increased use replaces part of the current consumption of petroleum products in these sectors.The development of the necessary transmission and distribution infrastructure to allow access to natural gas for higher percentages of end users in the building sector and the further increase in its use in industry and transport are priorities for the forthcoming period. The quantitative objective for this priority is to increase the direct use of natural gas in the final consumption sectors by at least 50% compared to 2017.

Finally, the implementation of all the necessary investments in final energy consumption sectors with a view to improving energy efficiency requires that more effective financing mechanisms are planned in order to increase and maximise the current levels of private capital leverage. The active involvement of the financial sector and the promotion of innovative financing mechanisms and market mechanisms, including energy performance contracts, are critical parameters for attaining this objective.

Energy Efficiency in Buildings

Since buildings are currently responsible for approximately 40% of energy consumption, there is a need to promote the improvement of the energy efficiency of buildings through renovation and modernisation, as well as to adopt corresponding measures for renewing the stock of end-of-lifecycle buildings, while at the same time using construction and demolition waste in conformity to the principles of circular economy. Reducing the energy consumption of buildings requires the increased use of energy-efficient and low-emission heating systems and the renovation or construction of smarter buildings, with improved insulation materials, inter alia, in full conformity to the principles of circular economy. The Energy Performance of Buildings Directive contributes to improved quality of life and makes a significant contribution towards the reduction in GHG emissions by 2050.

Another highly important policy is the optimal use of RES technologies to cover heating and cooling needs and of RES autoproduction systems to cover the needs of buildings for electricity, also by strengthening the role of consumers. These actions will also ensure a lower cost of living. However, the necessary methods and means must be provided, to help people make this transition. Improving energy efficiency in buildings has much potential for speeding up energy savings and contributing to the recovery of the economy after the Covid-19 pandemic.

Building on the momentum of the Renovation Wave initiative[28], there is scope for Greece to intensify efforts to improve the energy performance of the building stock with specific measures, targets and actions, while giving due attention to energy poverty. Further support for the renovation of public and private buildings could be provided through increased public funding and by leveraging EU and national budgets with private money, combining grants, lending, guarantees and loan subsidies. Greece is expected to provide a robust and comprehensive long-term renovation strategy, in accordance with Article 2a of the Energy Performance of Buildings Directive, which can contribute to the energy efficiency target and the recovery of the Greek economy following the Covid-19 pandemic.

The long-term renovation strategy is due to define a roadmap for decarbonisation by 2050 with ambitious milestones for 2030, 2040 and 2050, measurable progress indicators, expected energy and wider benefits, measures and actions to renovate the building stock, and a solid finance component with mechanisms to mobilise public and private investment.

Energy Efficiency in Transport

In the transport sector, the use of vehicles powered by alternative fuels and electricity, the sharp drop in unit energy consumption per type of vehicle, the use of second-generation biofuels, the complete electrification of railway infrastructure and the increase in the share of track-based modes of transport in the overall transport work will, by the end of the next decade, totally transform the technological structure and fuel mix used in the transport sector, thus impacting the national economy as a whole. Finally, given that Greece is a leader in shipping, it is important to promote emission reduction technologies in shipping in compliance with the decision of the International Maritime Organisation (IMO) of April 2018 for a 50% reduction in emissions by 2050, compared to 2008, and totally eliminating emissions by 2100.

(b) Cogeneration

Cogeneration is defined as the simultaneous production of power and heat (and/or cooling) from the same initial energy source. In general, cogeneration systems can cover all final energy uses (electricity, heating, steam production, cooling) and thus, they are used across a broad range of applications (e.g. greenhouses, residential complexes, manufacturing facilities, etc.). In addition, these systems allow for the dispersal of power generation units so that they reflect the needs of local consumption, offering high performance, avoiding losses in transport and increasing the flexibility of an area's power system.

The fuel most commonly used in cogeneration systems is natural gas, which, compared to other fossil fuels, has lower greenhouse gas emissions. In specific applications, as in agriculture companies, biomass may also be used. Greece has one of the lowest rates of cogeneration among the EU-28 member

[28] European Commission (2020), "A Renovation Wave for Europe – greening our buildings, creating jobs, improving lives", COM(2020)662 and SWD(2020)550, https://eur-lex.europa.eu/legal-content/EN/TXT/?qid=1603122220757&uri=CELEX:52020DC0662

states, even though it has a 40-year related tradition, initially in the industrial sector. In 2019, the total installed cogeneration capacity and distributed cogeneration units throughout the country was 233.4 MW, based on DAPEEP's data, which covers mostly the industrial sector, the primary and tertiary sectors as well as the district heating of towns. An appropriate legal framework can promote cogeneration, in conjunction with support of mechanisms for autoproduction, but Greece is lagging in long-term stability.

Also, the related legislation is characterised by complexity (e.g. frequent changes in energy laws, amendments, etc.), while the bureaucracy in licencing procedures is an obstacle for any investor wishing to become active in the sector.

Table 5.119 **Annual Electricity Generation from Cogeneration and RES in Greece, 2010-2019**

Year	Annual Electricity Generation from Cogeneration Units	Annual Electricity Generation from Distributed Cogeneration Units	Total Electricity Generation from RES and Cogeneration	CHP % of the Total
	GWh	GWh	GWh	%
2010	115	0	3,256.5	3.53
2011	142	0	3,959.5	3.59
2012	149	0	5,406.5	2.76
2013	119	943	9,156.0	1.30
2014	159	1,116	9,091.0	1.75
2015	188	1,121	10,051.0	1.87
2016	185	1,112	10,469.0	1.77
2017	195	984	11,552.0	1.69
2018	183.5	918	12,211.5	1.50
2019	186.5	876	13,357.5	1.40

Source: Hellenic Association for the Cogeneration of Heat and Power (HACHP)

According to studies undertaken before the financial crisis, there are significant prospects for cogeneration in several sectors of the Greek economy, e.g. in industry, in district heating from cogeneration units, in the primary and tertiary sector (hospitals, hotels, etc.) that can be financed by EU funds (e.g. via the Structural Funds and Cohesion Fund), but also for very small cogeneration for buildings. According to the Cogeneration Observatory and Dissemination Europe, the potential of Greece is estimated at 11.1 TWh/year of primary energy saving, as per the methodology of the Directive on Energy Saving (27/2012/EC). Considering the implementation of the aforementioned actions possible, the Observatory estimates the potential at 24 TWh/year of primary energy saving and the reduction of CO_2 emissions at 14 million tons.

Table 5.120 **Electricity Cost from Cogeneration and RES in Greece, 2010-2019**

Year	Cost for Cogenerated Electricity from Cogeneration Units and Distributed Cogeneration Unit, million €	Total Cost of Electricity from RES and Cogeneration, million €	CHP % of Total Cost
2013	67.1	1,747.5	3.84
2014	56.6	1,638.4	3.45
2015	56.2	1,476.4	3.81
2016	41.1	1,329.0	3.09
2017	38.5	1,691.4	2.28
2018	37.3	1,719.5	2.17
2019	42.6	1,848.8	2.30

(c) Planned New Projects

Launched in November 2020, the "saving-autonomous" programme (old "Saving at Home" programme) is currently seeing strong interest from homeowners. The programme has an €850 million budget and is intended at enabling around 600,000 homeowners to make their houses more energy efficient by 2030. The scheme enables homeowners to include the installation of a rooftop PV system, a residential battery, a smart power management system, and a charger for electric vehicles.

These and other interventions, such as thermal insulation, windows replacement, and the use of thermal solar collectors, are intended at reducing the energy consumption of all interested houses by around 9%. The funds for the programme are being provided by the EU's National Strategic Reference Framework (NSRF) for 2021-2027. Another important energy efficiency programme is the "Elektra programme", which strengthens the energy upgrading of public buildings by financing part of the required investments through investment loans, which will be repaid by the programme. It also provides for the participation of energy service companies, whereas payments to them, in the context of energy performance contracts, are guaranteed through securities.

Energy Investment Outlook

Taking into account large- and medium-sized energy projects already under development, but also assessing the dynamics of implementing planned projects, Greece appears to have a substantial energy related investment potential. This is currently estimated at above €45 billion over the next decade or about €4.5 billion on an annual basis.

As analysed in IENE's 2020 Annual Report on Greece's Energy Sector[29]. Table 5.121 summarises the anticipated energy investments in Greece over the next decade (2020-2030). These estimates are based on several assumptions, including that from 2021 and onwards the country will record growth, not recession, with an annual growth rate of 1.5%. More details about Table 5.121 are available at iene.eu.

Table 5.121 **Anticipated Energy Investments in Greece, 2020-2030**

	Expected Investments in million €
Oil	7,700
Natural Gas	2,800
Electricity	21,200
Energy Efficiency	11,000
Residential and Commercial Solar Power Applications	1,500
Research & Innovation	1,000
Total	**45,200**

Source: IENE

[29] IENE (2020), "The Greek Energy Sector – Annual Report 2020", https://www.iene.eu/articlefiles/greek%20energy%20sector%20study%202020_eng%201.pdf

HUNGARY

Hungary

Economic and Political Background

A second GDP release confirmed that the pace of economic contraction in Hungary moderated considerably in the fourth quarter of 2020, with GDP falling 3.6% year-on-year (previously reported: -3.7% y-o-y), following the 4.6% drop recorded in the previous quarter. Meanwhile, GDP expanded 1.4% on a seasonally-adjusted quarter-on-quarter basis in Q4 (previously reported: +1.1% q-o-q), following Q3's 11.0% rebound, which had marked the strongest expansion on record. Looking at the year as a whole, the economy shrank a heavy 5.0%, strongly contrasting 2019's 4.6% expansion.

Looking at the details of the release, while the external sector benefited from an improved international trade environment, the performance of the domestic economy was more mixed. Household consumption dropped 4.2% in annual terms following Q3's softer 2.1% decrease, amid downbeat consumer sentiment and tighter Covid-19 containment measures. However, fixed investment rebounded and grew 1.2% in the fourth quarter (Q3: -13.7% y-o-y), reflecting increasing investment in construction and in machinery and equipment. Meanwhile, public spending soared 6.2% (Q3: -2.6% y-o-y) amid the government's efforts to boost the economy.

On the external front, exports of goods and services expanded 1.7% in Q4 (Q3: -4.8% y-o-y), as easing lockdowns abroad supported foreign demand. Similarly, imports of goods and services increased 0.9% in Q4, following Q3's 4.5% plunge. Looking ahead, the economy is set to rebound markedly in 2021 following last year's pandemic-induced downturn. Domestic and foreign demand should strengthen amid loose fiscal and monetary policy stances, incoming EU funding and the gradual reopening of the global economy. Uncertainty regarding the availability of vaccines poses a downside risk, however.

IMF estimates that Hungary's GDP will expand by 3.9% in 2021, significantly higher than -6.1% in 2020.

In recent weeks, a new challenge has emerged in the continuing fight against Covid-19. A significant portion of Hungarians are not convinced of the importance of vaccination or are afraid of the alleged side effects of the vaccines. The first part of the task has been completed by the government, as it had been able to secure the supply of vaccines from various sources. However, if the vaccination rate cannot be accelerated due to public reluctance, the government would risk a second year of lockdowns. This would further deteriorate the business environment and affect the overall assessment of the government's performance, which of course could be reflected in the 2022 general elections.

In other words, the opposition camp has a political stake in the mismanagement of the Covid 19 crisis now. This is why political debates in Hungary still revolve around the details of the vaccination, including the origin of the vaccines, their reliability and safety. This briefing first focuses on to the details of these debates (vaccination readiness, the origin of vaccines) and the details of a new round of lockdown, then moves on the analysis of the latest polling data.

Energy Policy

(a) National Energy Policy

A series of documents, such as the National Energy and Climate Plan in line with the requirements of the EU or the Report on the Impact of Climate Change on the Carpathian Basin, along with the National Climate Change Strategy and the derived National Action Plan Addressing Climate Change in line with the requirements of the UNFCC, provide the strategic basis for Hungary's climate mitigation actions. The National Energy Strategy 2030 with an Outlook to 2040 document, approved in 2020, replacing the previous document of 2011, provides the strategic basis and defines the energy- and climate policy priorities of the country.

The strategy is laid with the binding EU 2030 goals in mind, and among others is designed to attain a number of policy goals while ensuring energy sovereignty, decarbonization of energy production through the utilization of nuclear and renewable technologies and maintaining sustainable energy prices. These policy goals can be described as follows:

- The final energy consumption of Hungary -in parallel with strong economic growth- should not exceed the 18,7 Mtoe of 2005, further increase beyond 2030 should only be supplied by carbon neutral energy sources;
- The GHG emissions of the country should be at least 40% below that of 1990 in 2030.
- Decrease the need for energy imports in general and decrease the share of electricity imports in the final electricity consumption from 32% (2013-2017 average) to below 20% by 2040;
- Increase the use of renewable energy sources to reach 21% in the gross final energy consumption by 2030 from 13,3% in 2017;
- 90% CO_2 emission free electricity generation by 2030 based on nuclear and solar technologies;
- Increase the share of the local RES production in the electricity consumption to 20% by 2030 and to close to 30% by 2040;
- The installed total solar capacity should exceed 6,0 GW by 2030 and approach 12,0 GW by 2040;
- Incentivize the use of smart meters in order to increase the flexibility of the grid - install ca. 1 million smart meters;
- Enhance the utilization of the country's geothermal potential;
- The local lignite assets should be considered strategic reserves and current lignite capacity at Mátrai Erőmű should be converted to low-carbon technologies;
- The energy and climate goals shall be met by keeping the energy costs low.

The strategy estimates that the costs of reaching the 2030 climate and energy goals are in the range of 14.700 billion HUF (44.5 bn EUR current prices).

(b) Governmental Institutions

The key institutions and their role in policy making include the following entities.

The Ministry for Innovation and Technology is, among others, responsible for formulating and implementing the economic, energy, climate, and transport policies of Hungary. Within these capacities the ministry also prepares and implements the strategic and policy documents to comply with Hungary's climate policy obligations originating from the European Union membership.

Ministry of Finance is, among others, responsible for setting and implementing the fiscal policies of Hungary, along with the preparation and monitoring of the budgetary processes. The ministry is also responsible for the administration of the European Union funds. In those capacities the Ministry of Finance has strong influence over the establishment and realization of economic, energy, climate, and transport policies.

Hungarian Energy and Public Utility Regulatory Authority (HEA), is the regulatory body of the energy and public utility market, supervising the national economy sectors of strategic importance.

HEA, as an independent regulatory authority entrusted with provision making power was established under Act XXII of 2013 as the successor of the Hungarian Energy Office (HEO) that was set up under Act XLI of 1994 on Gas Supply. The Authority's responsibility covers licensing, supervision, price regulation, tariff-and fee preparatory tasks in the fields of electricity, natural gas, district heating as well as in water utility supply, besides pricing of public waste management services.

As the official statistical body, HEA also performs standard national energy-statistics related tasks and complies with the data reporting obligations to various national and international bodies and organizations. As part of the National Statistical Data Collection Program, HEA liaises with roughly 5700 data suppliers. In cooperation with partners, maintaining security of supply and protecting retail, public and industrial consumers are also among HEA's key activities.

Keeping consumer interests in mind, HEA continuously supervises the license holders' billing, contract management and customer service activities.

The Act LVII of 2015 on Energy Efficiency has entrusted HEA with numerous regulatory, supervisory, energy-statistics and related communication tasks. HEA - among others - defines the methodology for the assessment of expenditures and revenues related to the power plants' use of waste heat and that of cogeneration as well as the requirements for the preparation of cost-benefit analysis. In view of the above, HEA enhances the reduction of energy consumption costs and the conservation of environmental resources for future generations.

HEA maintains close international relations at European, regional, and bilateral levels, its experts participate in the activities of the highest forums and organizations. Legal basis includes: Act 22 of 2013 on the Hungarian Energy and Public Utility Regulatory Authority, Act 86 of 2007 on Electricity, Act 40 of 2008 on Natural Gas Supply, Act 18 of 2005 on District Heating, Act 209 of 2011 on Water Public Utility Service and Act 185 of 2012 on Waste management.

Hungarian Atomic Energy Authority (HAEA) as a government office, is responsible for the regulatory tasks in connection with the use of atomic energy exclusively for peaceful purposes, the safety of nuclear facilities and transport containers, as well as for the security of nuclear and other radioactive material and associated facilities.

One of the most important international expectations on the safe and secure use of atomic energy is that the supervisory authority shall be independent of the interests of producers, owners, service providers, as well as of the state organizations having role in the promotion of the use of atomic energy. In Hungary, several stipulations of the Atomic Act and its implementation decrees guarantee the enforcement of the international expectations on independence.

The Hungarian Atomic Energy Authority, during its regulatory oversight activity, conducts comprehensive, targeted, regular and occasional inspections, during which it verifies the compliance with the requirements set forth in relevant laws and in the nuclear safety code, the accomplishment of the measures ordered by the Authority, as well as the safety and security of the various use of atomic energy.

FGSZ Földgázszállító Ltd. On the basis of the certification included in the Resolution of the HEA, as of 7 February 2012 is the natural gas Transmission System Operator (TSO), operates in accordance with the Independent Transmission Operator (ITO) model and as such is the owner and operator of the Hungarian high-pressure natural gas pipeline system servicing gas distribution companies, power plants and large industrial consumers. FGSZ focuses on contributing to the regional-level connection of the high-pressure long-distance pipeline systems of the surrounding countries, thereby facilitating the improvement of the security of supply, the availability and diversification of sources and the market conditions of the region. FGSZ prepares and upon approval by HEA carries out the natural gas transmission network development strategy. FGSZ is a member of the European Network of Transmission System Operators for Gas - ENTSOG.

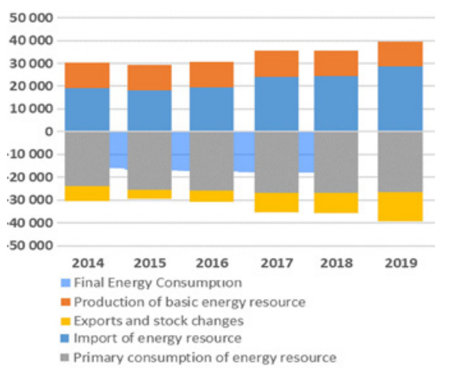
MAVIR Hungarian Independent Transmission Operator Company Ltd. On the basis of the certification included in the Resolution of the HEA as of 13 March 2012, MAVIR is operating in accordance with the ITO model, thereby MAVIR is the owner and operator of the transmission network within a vertically integrated electricity corporation. MAVIR, among others, is responsible for maintaining the capacity balance of the national electricity system and for balancing deviations of the balancing groups from planned targets, it provides for the reliable, efficient and secure operation of the Hungarian electricity system including required reserve capacities of generation and transmission, controls and augments the assets of the transmission system, performs all renewal, maintenance and development required for a proper and reliable supply, ensures an undisturbed operation and further extension of the electricity market and of the balancing group system supporting the market, and ensures access for system users on equal terms, synchronizes the operation of the Hungarian electricity system with the neighboring systems, coordinates professional international cooperation activities (among others as a member of the European Network of Transmission System Operators for Electricity - ENTSO-E), prepares the network development strategy and puts forward proposals for the development of the generation pool.

Energy Demand and Supply

Primary consumption of energy resources remained stable in Hungary in the last couple of years, with 26,9 Mtoe in 2017 and 26,4 Mtoe in 2019. Production of basic energy resource was slightly decreasing, with 11,3 Mtoe in 2017 and 10,7 Mtoe in 2019. In parallel, however, the import of energy resource has increase significantly from 24,1 Mtoe to 28,8 Mtoe.

The growth of the combined production and import compared to the stagnating demand resulted in increased energy export (mostly transit) (ca. 7,5 Mtoe in 2017 and 10,4 Mtoe in 2019[1]).

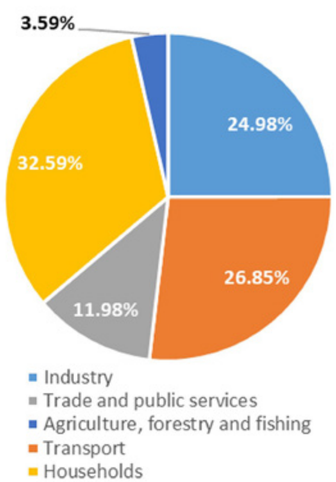
Figure 5.127 **Consolidated primary energy balance of Hungary (ktoe)**



Source: KSH/HCSO 3.8.1. Primary energy balance (1990-) [petajoule] and 5.7.1. Final energy consumption (1995-)* (ktoe); own elaboration

In 2017 the final energy consumption was 17.337 ktoe, which grew to 17.833 ktoe in 2018. The largest consumer sector was one for the households with 32,6%, followed by transport and industry sectors representing ca. one-fourth of the final energy consumption.

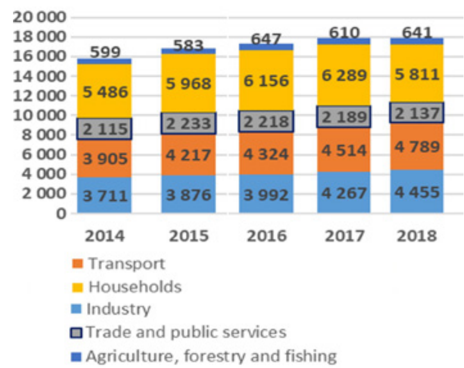
Figure 5.128 **Final Energy Consumption by sector 2018 (%)**



Source: KSH/HCSO 5.7.1. Final energy consumption (1995)* (ktoe); own elaboration

This sectoral breakdown stayed roughly the same in the previous years as well.

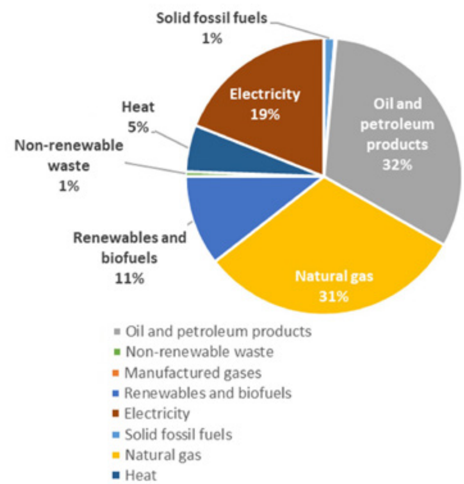
Figure 5.129 **Final Energy Consumption by Sector (ktoe)**



Source: KSH/HCSO 5.7.1. Final energy consumption (1995)* (ktoe); own elaboration

Natural gas and oil and petroleum products represent ca. one-third of the final energy consumption, with electricity representing ca 20%. The remaining ca. 20% is shared among renewables and biofuels, non-renewable waste, heat, and solid fossil fuels.

Figure 5.130 **Final Energy Consumption by Fuel 2018 (%)**



Source: HEA - National detailed Energy Balance - Eurostat format, 2018; own elaboration

In the years following up to 2018 the share of oil and petroleum products has slightly increased, whereas the share of renewables and biofuels has decreased. The share of natural gas and electricity stayed practically the same.

Figure 5.131 **Final Energy Consumption Breakdown 2014-2018 (ktoe)**

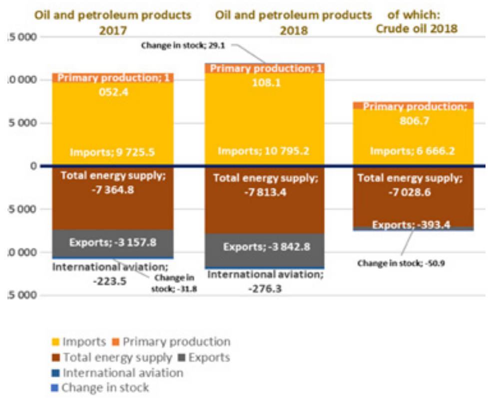
Figure 5.132 **Total Oil and Petroleum Products Balance 2017-2018 of which Crude Oil 2018 (ktoe)**



Source: HEA 7.4 National detailed Energy Balance - Eurostat format, 2018; own elaboration

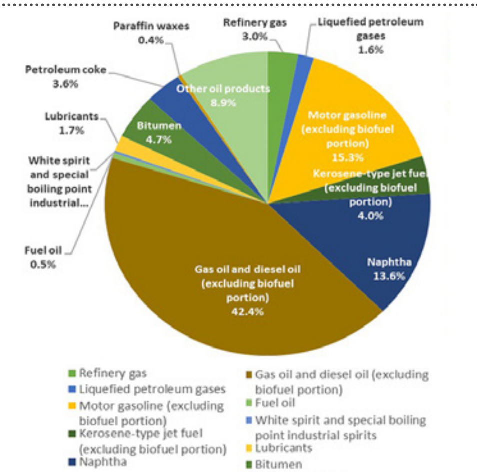
The Energy Market

(a) Oil and Petroleum Products

In 2018, the gross inland consumption of oil and petroleum products[2] was 8089,6 ktoe (7588,3 ktoe in 2017, a 6.6 % increase) or 162,457 barrels/day, out of which 7028,6 ktoe was crude oil. The import share of the gross inland consumption of oil and petroleum products was 133.44%[3] in 2018 (5.3 % higher than in 2017). The reason for the above 100% value is that most exported products are produced from import feedstock. The primary production of oil and oil products' share in the gross inland consumption was 13,7% in 2018 (13,9% in 2017). The share of the primary production of crude oil in the gross inland consumption of crude was 11,5% in 2018. According to HEA, the annual production of crude oil in Hungary in 2018 was 0.000808 thousand million tons (808 kt/y) or 16.226 barrels/day. This means that indigenous production covers approximately 13.6% of total oil consumption, whereas the production of other primary oil in 2018 was 0,000295 thousand million tons per year (295 kt/y), meaning that the total supply of crude and other primary oil was 0,001103 thousand million tons per year (1.103 kt/y) or 22.150 barrels/per day.

Refineries and petrochemical industry's transformation input was 8.426,7 ktoe in 2018 (6,9% increase on 2017), whereas transformation output thereof was 8.364,7 ktoe (6,9% increase on 2017). The product with the highest share in refinery output was gas oil and diesel oil with 42,4%, followed by motor gasoline 15,3%; naphtha had the third largest share with 13,6%.

Figure 5.133 **Refinery output 2018 (%)**



Source: HEA 7.4 National detailed Energy Balance - Eurostat format, 2018; own elaboration

2 Total Energy Supply + International Aviation

3 It is above 100%, as most product export is transformed from import feedstock. Gross Inland Consumption = Primary Production + Imports -Exports +/- Stock Change (Eurostat format Energy Balance)

According to the Mining and Geological Survey of Hungary (MBFSZ/MGSH), Registry on Mineral Raw Materials and Geothermal Resources, the contingent reserves of crude oil (1) oil on 1 January 2019, were 5.103 thousand million bbl (811,83 Mm3), thereof 1.725 thousand million bbl conventional and 3.378 thousand million bbl unconventional; whereas the proven reserves (2) were 0,517 thousand million bbl (82,12 Mm3), thereof 0,148 thousand million bbl conventional and 0.368 thousand million bbl unconventional. According to their records, there were 325 crude oil and natural gas mining plots in the country on 1 January 2019.

Within the framework of the mining concession system launched by the Government in 2013, the Ministry of Innovation and Technology issues public invitations to tender the prospecting, exploration, and production of hydrocarbons in the designated concession areas (blocks). Participation in the tendering process is open to any Hungarian or foreign natural person or entities with the capacity to act, and any transparent organization as defined by Act CXCVI of 2011 on National Assets. Additional legislation concerning prospection, exploration and production of hydrocarbons are the following: Act XVI of 1991 on concessions ('the Concessions Act') and Act XLVIII of 1993 on mining ('the Mining Act'). The following maps provide an overview of oil and oil-associated gas fields.

MOL Hungary Plc, member of the MOL Group is the owner and operator of the Danube Refinery in Százhalombatta, with a capacity of 165.000 bpd of crude oil and a Nelson Complexity Index (NCI) of 10,6. It is one of the largest refineries in CEE. "The Danube Refinery is operated as a hub in co-ordination with the MOL-owned 124 kb/d refinery (NCI 11,5) in Bratislava (Slovak Republic) and a significant amount of intermediate products are exchanged between the two." (IEA)

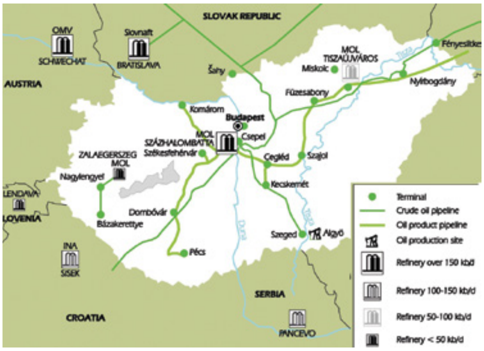
There are also two smaller MOL Plc. refineries in Tiszaújvaros (60 kb/d) and Zalaegerszeg (10 kb/d) which do not process crude oil at present. "There is no oil port in Hungary, but there is the option to export and import refined products by barge from Komárom and Százhalombatta. A large proportion of product exports from the MOL refineries are transported by barge on the Danube River." (IEA)

Crude oil is supplied to Hungary through pipelines. The Southern Friendship (Druzhba) pipeline system, originating in Russia and transiting Belarus and Ukraine, is Hungary's main crude oil supply channel. The section of the older Druzhba I pipeline (built in 1961) between Százhalombatta and Sahy has recently been fully renovated and increased its capacity from 70 kb/d (3,5 Mt/year) to 120 kb/day (6.0 Mt/ear). It enables supplies to Hungary from its northern border with the Slovak

Republic. The Druzhba II (built in 1971) has a capacity of 160 kb/d (7,9 Mt/year) and supplies Hungary from its eastern border with Ukraine. The pipeline terminates at the Duna refinery at Százhalombatta (via the Tisza refinery). Domestic oil production is transported via an internal pipeline between Algyő, where oil is produced, and the Százhalombatta refinery." (IEA)

The Adria oil pipeline section between Sisek and Százhalombatta has also undergone recent renovation and increased its capacity from 200 kb/d (10 Mt/yr) to 280 kb/d (14 Mt/yr), roughly equal to the total processing capacity of the Bratislava and Duna refineries combined. This pipeline links the Duna refinery to the Croatian port of Omišalj. This pipeline was originally intended for the delivery of crude oil imports from the Middle East or Africa to Hungary but was mainly used for transporting Russian crude oil in the opposite direction, transiting to the Sisek refinery in Croatia. In recent years, its use for transporting cargoes from Omišalj (the pipeline's original purpose) has increased. Hungary is also linked to the Eastern oil product pipeline that transports product from Russia's refining centers via Ukraine. This enables MOL to purchase gasoil feedstock from Russia for further processing. (IEA) According to the IEA total storage capacity in Hungary in 2015 was 3,1 mcm (19,5 mb): 1,1 mcm of this capacity is for crude oil storage and 1,9 mcm for product storage. There has been no substantial change since then.

Map 5.40 **Hungary's Oil Facilities**



Source: IEA - Energy Policies of IEA Countries - Hungary 2017 Review

The Hungarian wholesale and retail oil markets are fully liberalized. The largest market player in Hungary is MOL, which is an integrated international oil and gas group. The group has also extensive upstream and downstream interests in other countries. It is active in all downstream activities, including refining, pipelines, and retail. The wholesale market is dominated by MOL and OMV, the main regional refiners.

At the end of 2017 there were 2.077 filling stations in Hungary. Based on the website of the companies, there are currently 472 MOL, 194 OMV, ca 170 Shell, ca 75 Normbenz (under Lukoil brand) (2020 May) and ca. 850 are independently owned. "There have been a number of mergers and acquisitions in the retail market over [the recent years]. For example, in 2014, Normbenz acquired the Lukoil stations in Hungary (and in Slovak Republic) but kept the Lukoil brand. In 2016, MOL acquired all ENI stations in Hungary, which officially became MOL property from 1 August 2016." (IEA)

(b) Natural Gas

Infrastructure

TSO FGSZ operates 5.874 km of gas transmission network with a diameter of 80-1400 mm. Eight compressor stations (Beregdaróc, Nemesbikk, Hajdúszoboszló, Városföld, Csanádpalota, Szada, Báta, Mosonmagyaróvár) provide the pressure for the operation of the system at 40-75 bar. The Natural Gas is delivered at ca 400 delivery stations to the Distribution System Operators (DSO) and to industrial consumers. There are also 17 main junctions (hubs) of the long-distance pipelines. FGSZ also operates the gas interconnectors to all neighboring countries, except Slovenia, which is in planning phase. The system is operated via six territorial control centers and a national headquarter: the dispatching center in Siófok. The task is carried out by the National Telemechanical System (NTS), whereas the data transmission belongs to the Supervisory Control and Data Acquisition (SCADA) function.

Map 5.41 **Hungary's Gas Transmission Network** [4]

Source: HEA-FGSZ - Data of the Hungarian Natural Gas System 2018

Currently there is a network of ca. 84.100 km of distribution pipeline Network operated by ten licensed DSOs, with ca. 3,26 million distribution pipeline gas meters. There are ca. 3,47 million consumers connected to the natural gas system, out of which 3,26 million are household consumers.

Table 5.122 **Technical Data of Natural Gas Transmission and Distribution Pipelines as well as Storage Facilities**

[4] On October 4, 2019 at 6 a.m., FGSZ took over the operation of the 92 km long natural gas transmission pipeline from MGT Ltd. connecting Hungary to Slovakia thus, the entire, nearly 6000 km long high-pressure natural gas transmission pipeline system of Hungary is now operated by FGSZ. - FGSZ Press Release - 04 October 2019.

There are 5 underground gas storage facilities in Hungary, with a combined working gas volume of 6,33 bcm; withdrawal capacity of 78 mcm/d; injection capacity of 45,3 mcm/d.

Map 5.42 **Gas storage facilities in Hungary**

Source: GIE Storage Map 2018

Gas Consumption

Domestic gas consumption[5] in 2019 was 10,08 bcm. The average domestic gas consumption in the 2017-2019 period amounted to 10,12 bcm/y, with a slightly increasing trend. The average y-o-y increase in annual domestic gas consumption was 3,94% in the 2014-2019 period. However, it must be noted that gas consumption is strongly influenced by the number of heating days occurring each year. The domestic production[6] in 2019 amounted to 2,13 bcm vs 2,46 in 2014. The trend of production was slightly decreasing -2,4% in the period of 2014-2019. The difference between domestic consumption and production corresponds to imports. The share of imports in the domestic consumption reached 78,8% in 2019 vs 70,5% in 2014. The share of natural gas imports in primary energy import reached 44,29% in 2018 vs. 32,4% in 2015. The natural gas intensity of the economy however has decreased significantly to ca. 60% of the value in year 2000.

The Gas Market

"The imported and domestically produced natural gas is sold to domestic users by traders and universal service providers. Natural gas distribution systems are operated by 10 regional distributor companies. Most of the regional distribution activity is carried out by five large companies which are geographically divided. Since market opening in 2004 the retail market has been characterized by a dual structure. In the free market segment, the prices are formed by the market. Consumers eligible for universal service can get natural gas on a regulated (maximized) price.

[5] Does not include the production directly delivered to consumers, associated gas from thermal water production, domestic CH4 production and the auto consumption of producers.

[6] Certified quantity delivered to the natural gas grid from the producers. Does not include production delivered to island networks, directly to consumers or auto consumption of the producers.

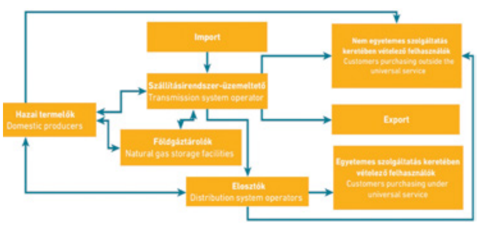
The customers eligible for universal service are the household consumers, other customers with purchased capacity below 20 m3/hour, and the local governments up to the capacity to supply consumers living in rented apartments provided by local governments.

Non-eligible customers either purchase natural gas from the competitive market as earlier, or entered the free market upon termination of their eligibility to universal service (customers with medium and low consumption and district heating generators)." (HEA)

In 2018, 3,7 bcm of natural gas has was sold within the universal service for eligible customers (3,35 bcm household customers and 0,36 bcm other) and 4,8 bcm was sold to non-eligible customers in the wholesale market (99,9% non-household customers).

The universal supplier is the NKM Energia Zrt, a subsidiary of the NKM Nemzeti Közművek Zrt, a subsidiary of the state owned, MVM Group. The HHI competition index of the sales to household end users was 9984 in 2018. In 2018, there were 43 companies active in the wholesale market and the HHI competition index of the sales in the wholesale market was 1987 in 2018. The model of the domestic natural gas sector is presented in Figure 5.136.

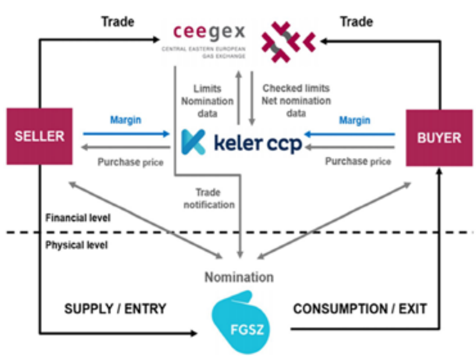
Figure 5.136 **Current operational model of Hungary's domestic Natural Gas sector**



Source: Source: HEA-FGSZ - Data of the Hungarian Natural Gas System 2018

The Central Eastern European Gas Exchange CEEGEX Ltd[7] is the organized gas market providing physical within-day and day-ahead market trading on the Hungarian Virtual Point (MGP) and on locational points. Total spot volume reached 34.338 GWh in 2019, a four-fold increase compared to 8405 GWh volume of 2018. There are 37 exchange members and two market makers. In 2019, the premium over the CEGH price was between 0,2 – 2,5 EUR/MWh and 0,2 - 4 EUR/MWh over TTF.

Figure 5.137 **Nomination/position netting Limit check**



Source: HUPX Group Brochure 2020 - Energy Business Motion

Gas future contracts[8] are available on the Hungarian Derivative Energy Exchange - HUDEX Energy Exchange Ltd., member of the HUPX Group., through Currently, there are two market makers, RWE and MFGK on this market.

(c) Solid Fuels

Balance

In 2018, the gross inland consumption of solid fossil fuels was 2.120,3 ktoe (2.234,7 ktoe in 2017, a 5,1% decrease), out of which 1.235,7 ktoe was lignite. In 2018, the import share of the gross inland consumption of solid fossil fuels was 58,63% (2,3% higher than in 2017).

[7] Part of the HUPX Group, a subsidiary of the electricity TSO MAVIR, a subsidiary of the state owned MVM Group
[8] Balance of Month, Seasonal, Yearly contracts

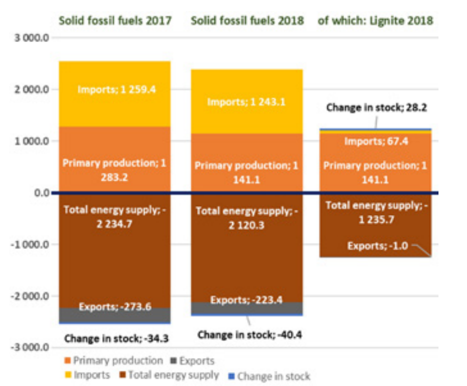
The primary production of solid fossil fuels compared to the gross inland consumption was 53,8% in 2018 (3,6% lower than in 2017). 100% of primary production was lignite.

Lignite represented 58,3% (1.235,7 ktoe) of the gross inland consumption in 2018, 92,.3% of which was from primary production. 92,1% of the lignite was used in electricity and heat generation, the remaining was used by households and industry.

In 2018, coking coal represented 80,8% of the solid fossil fuel imports. After correction with stock changes and statistical differences, 100% of the imported coking coal was used in coke ovens (977,2 ktoe) to produce coke (668,7 ktoe) for steel production.

As far as electricity production is concerned, Hungary is self-sufficient in terms of indigenous solid fuel resources (lignite) whereas the import supplies are exclusively destined for coking coal which is used in steel production (ISD Dunaferr Zrt.). In 2018, 80,9% of the solid fossil fuel exports was for coke oven coke (re-export) and 18,7% was coal tar. There were also marginal lignite exports as well.

Figure 5.138 **Solid Fossil Fuels Balance 2017-2018 and of Lignite 2018 (ktoe)**

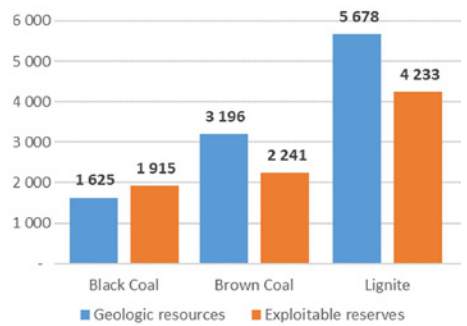


Source: HEA - 7.4 National detailed Energy Balance - Eurostat format, 2018; own elaboration

Resources

According to the Mining and Geological Survey of Hungary (MBFSZ/MGSH) and the Registry on Mineral Raw Materials and Geothermal Resources, the geological resources of lignite on 1 January 2019, were 5,678 million tons (mt), whereas the exploitable reserves were 4,233 mt. The geological resources and exploitable reserves of black[10] - and brown coal are highlighted in Figure 5.139.

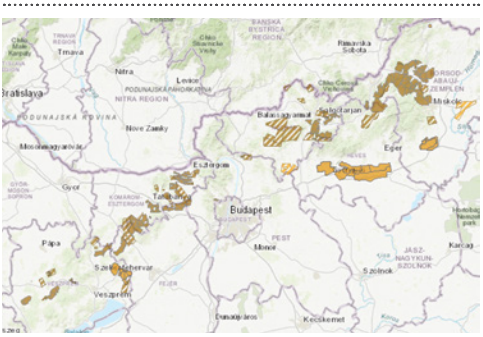
Figure 5.139 **Geological Resources Inventory of Solid Fuels in Hungary in 2019 (mt)**



Source: Mining and Geological Survey of Hungary - Inventory of Mineral Resources as of 1 January 2019; own elaboration

The following map (Map 5.43) provides an overview of the current and prospective black coal, brown coal, and lignite deposits.

Map 5.43 **Current and prospective black coal, brown coal, and lignite deposits in Hungary**



Source: Mining and Geological Survey of Hungary - Cadaster of Mineral Raw Materials - Online Map

9 Import share of gross inland consumption + primary production of solid fossil fuels combined are higher than 100% due to export.

10 Attenuation is higher than loss (Geologic reserve + attenuation - loss - pillar = Exploitable reserve) /quantity of exploitable coal + interim waste rock may exceed the registered geologic reserve!

The following map (Map 5.44) provides an overview of operative, suspended, and closed coal and lignite mining plots and ongoing prospecting activities.

Map 5.44 **Operative, suspended, and closed coal and lignite mining plots and ongoing prospecting activities in Hungary**

Source: Mining and Geological Survey of Hungary - Cadaster of Mineral Raw Materials - Online Map

Lignite is mined in Visonta and Bükkábrány through strip mining. The mines supply the Mátra power plant, the local population and also cover domestic demand in industry.

Strategy and Investments

With regard to future divestments, the operating permit of the last lignite block at the Mátra PPT expires in 2029, while other permits expire by 2025. The power plant is the second largest PPT in Hungary (896,3 MW installed capacity and ca. 17% of produced electricity), thus plays an important supply security role, therefore the National Energy Strategy 2030 document foresees the replacement of its lignite power generation capacities with low(er) GHG intensity technologies. According to NES a new CCGT plant (potentially 500 MW) is foreseen, along with additional solar capacities and the potential utilization of municipal-waste for power generation on this site. NES foresees keeping the more modern lignite plants as strategic reserve, due to the existing, significant lignite deposits, while completely shutting down the others. The Mátra PPT currently emits ca 50% of the CO_2 emissions in the power sector which constitutes 14% of total emissions.

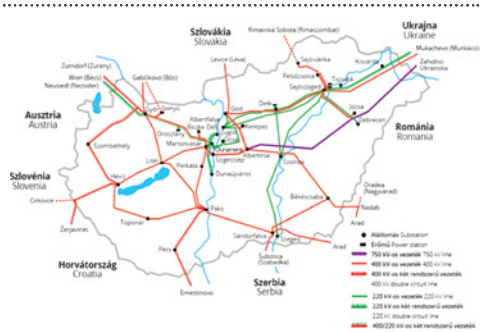
Apart from the Visonta strip mine site, there are no more operative prospecting permits, so no investments are foreseen in this sector. Additionally, although public discussion is taking place for years, the current energy strategy document does not foresee the application of clean coal technologies.

(d) Electricity

Infrastructure

In 2018, the TSO MAVIR operated 4861 km of high-voltage overhead lines and cables (with a route length of 3813 km) in the voltage range of 132 kV to 750kV. The TSO also operated 33 substations throughout the country, along with the interconnectors with all neighboring countries, except for Slovenia where the project is in permitting phase in Slovenia according to ELES, the Slovenian TSO; according to MAVIR the project does not require significant CAPEX in Hungary. MAVIR also operates the market of ancillary services and the balance group system as well as allocates the cross-border capacities.

Map 5.45 **Hungarian Electricity Transmission Network on 31 December 2018**



Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018

The route length of the distribution network operated by the six licensed DSOs was 161.578 km in 2018, out of which 6.377 km was high-voltage, 67.202 medium-voltage and 87.999 km low-voltage overhead lines and cables.

[11] Dr. László Palkovics, Minister of Innovation and Technology - https://www.kormany.hu/hu/innovacios-es-technologiai-miniszterium/hirek/korszerusitve-mukodhet-tovabb-a-matrai-eromu

Balance

The domestic electricity consumption increased from 40,12 TWh in 2017 to 41,2 TWh in 2019. The average annual growth of domestic consumption from 2014 until 2019 was 2,2%. The exports showed high fluctuations in the previous 3 years and ranged between 4,27 TWh per year in 2018 and 7,27 TWh in 2019, whereas the import share of the total consumption[12] remained high at around 37%. The import share in the electricity consumption has historically been high, although fluctuated between almost 40% and 8,1% since 1990. With the better access to cheaper electricity prices in neighboring markets and also thanks to the day-ahead market coupling of the CZ-SK-HU markets since September 2012 and the RO market in November 2014, the import share increased and remained high.

Also, the different installed the capacity mixes and the lower Marginal Cost of these countries compared to Hungary can explain the high import share.

An additional reason for the increased import share is the fact that domestic production has decreased by ca. 10% since 2010 -37,371 TWh in 2010 vs 33,936 TWh in 2019- whereas the total consumption has increased by 13,8% (export by almost 55% and domestic consumption by 14%).

Figure 5.140 **Hungary's Electricity Generation and Consumption, 2018 (GWh)**

[12] Domestic Consumption + Export

Maximum gross peak system load in 2018 was 6.869 MW on 19 December (1,29% increase from previous year and 6,3% increase since 2014). Minimum gross peak load was 4.502 MW on 20 May. Maximum gross domestic generation was 5.196 MW on 20 December. Daily summer peak load occurred on 21 June with 6.358 MW (6.357 MW in previous year on 28 June 2017).

Figure 5.143 **Annual Duration curve of the Hungarian Electricity System**

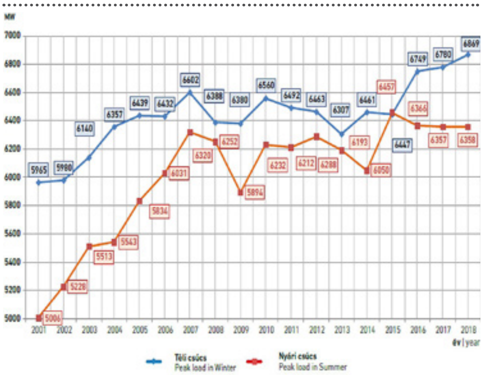
Figure 5.144 **Winter and Summer peak loads, 2001-2018**

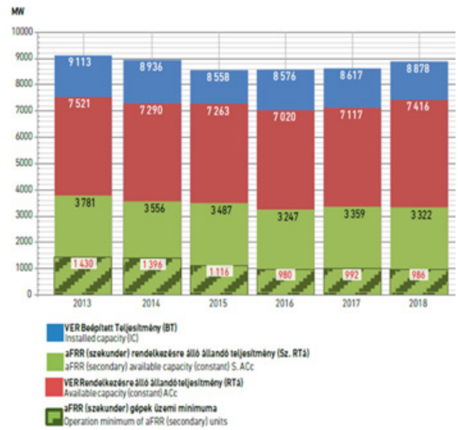


Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018

Power Plants and Generation

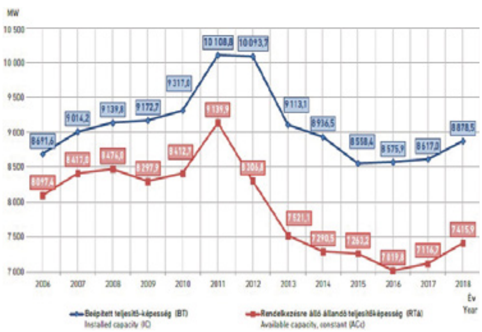
Hungary's total installed capacity at the end of 2018 was 8.878 MW which represents a 3% increase compared to the end of 2017. Out of this installed capacity, 6.923 MW were large power plants, whereas 1.955,5 MW were small power plants.

Figure 5.145 **Installed and available capacities in the Hungarian Electricity System**



Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018

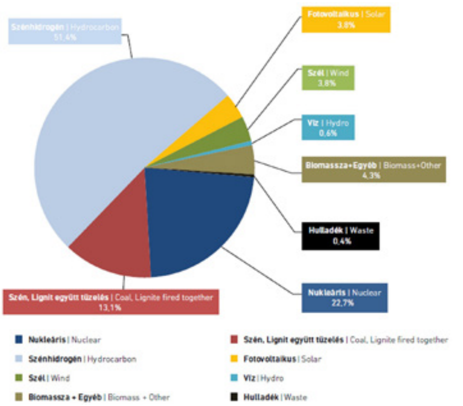
Figure 5.146 **Development of the capacity of the Electricity System on 31 December**



Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018

The highest share of the installed capacity, based on the primary energy sources was hydrocarbon-based power plants representing 51,4% of the installed capacity, followed by nuclear 22,7% and coal-lignite with 13,1%. Renewables (solar, wind, hydro, biomass + other) represented ca. 12,4% of the installed capacities. Although the data was not available at the close of editing, thanks to significant increase in solar installed capacities, the share of renewables is set to increase by 2020 and beyond.

Figure 5.147 **Primary Energy Sources of Domestic Power Plants on 31 December 2018**

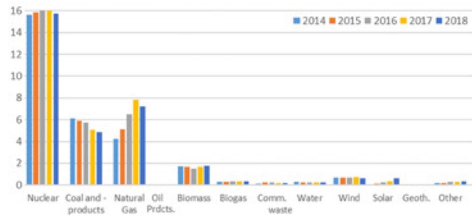


Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018

Figure 5.147 shows the power plants which are subject to license. There was also 333,7 MW of installed capacity corresponding to small-scale household power plants at the end of 2018, a significant, 38,5% jump compared to 2017 and more than 100 times than in 2011 (3,17 MW). According to HEA, the installed capacity of small-scale household power plants reached 462,36 MW by the end of 2019, 99,6% of which is solar.

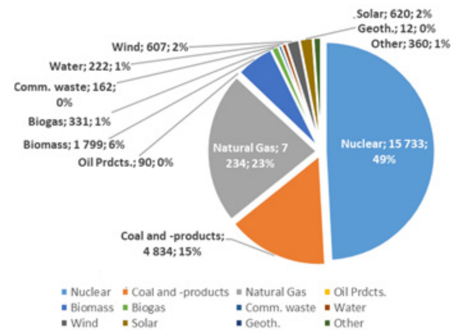
Nuclear power dominates the power generation with ca. 50%. Natural gas represents 23%, whereas coal and coal products (lignite) based power plants produce 15% of the electricity generated in Hungary. If biogas and biomass-based generation are considered carbon neutral, then 60,38% of the power generation was carbon free in 2018[13]. A slight decrease from the 63,5% of 2014.

Figure 5.148 **Gross Electricity Production by Source 2014-2018 (TWh)**



Source: HEA - 4.2 Gross Annual Power Generation 2014-2018; own elaboration

Figure 5.149 **Gross Electricity Production by Source 2018 (GWh,%)**



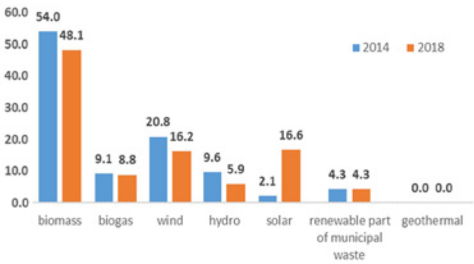
Source: HEA - 4.2 Gross Annual Power Generation 2014-2018; own elaboration

The share of renewable resources and waste in electricity consumption increased slightly between 2014 - 7,4% and 2018 - 8,1%.

Biomass dominates the renewable power generation in Hungary corresponding to almost half of the RES generation in 2018. However, the share of solar generation was already increased significantly, reaching 16,6% of RES generation in 2018. This increase is expected to continue due to the newly installed solar capacities (ca. 330MW end of 2017 vs. ca. 1.400 MW end of 2019 including household and commercial plants) which is expected to increase the share of RES generation as well.

[13] Carbon-free at the moment of generation, but not on a life-cycle basis.

Figure 5.150 **Share of renewable resources and waste in electricity consumption (2014 vs 2018) [%]**



Source: HEA - 4.2 Gross Annual Power Generation 2014-2018; own elaboration

With regard to investments, the National Energy and Climate Plan foresees a large increase of installed solar capacities to 6.500 MW by 2030 and potentially to 10.000 MW by 2040. By the end of 2016, HEA had issued permits for ca. 2.000 MW of small solar (not household) PPTs in the so call Compulsory Feed In regime (Kötelező Átvétel - KÁT). Estimates vary between 60-90% on how many of these permits will result in actual installations. Hence, the validity of the permits was prolonged until the end of 2021.

During the first, auction-based support scheme tender, known as the Renewable Energy Support System (Megújuló Támogatási Rendszer - METÁR), HEA awarded a total of 157,54 MW capacities. The winners obtained a weighted average price of 24,81 HUF/kWh in the small solar PPT category and 21,69 HUF/kWh in the large solar PPT category.

The other pillar of the policy for a 90% target of CO_2 emission free electricity generation by 2030 is the retention of the existing nuclear generation capacities, currently 2012,8 MW (4 reactor blocks) which were planned to be shut down between 2032 and 2037 despite their extended lifetime. On 14 January 2014, the Hungarian Government signed an inter-governmental agreement with the Russian Federation[14] for the construction of two new VVER nuclear blocks with at least 1000MW capacity each.

Additionally, on 28 March 2014 the Hungarian Government and the Russian Federation signed an inter-governmental loan agreement to finance the construction of the power plant with a maximum EUR 10 bn credit. The EPC Contract has been signed between MVM Paks 2 Ltd[15] and JSC NIAEP [16]. Currently there is no official commissioning date for the project but expert opinions name the early 2030s as the possible startup date of operation.

Market

"The power plants sell the generated electricity to traders and universal service providers, who resell it on the wholesale market or supply the customers directly. Electricity flows from the generators to customers through transmission and distribution networks. The transmission and distribution activities are to be performed by unbundled companies in line with the provisions of EU 3rd Energy Package.. The current structure of the Hungarian electricity market essentially took shape around 1995, when most, large power plants, the public utility suppliers and the distribution networks were privatized. Presently, domestic power plants sell most of their power generation through agreements concluded with the Hungarian Electricity Ltd. (MVM): through framework contracts to the universal service providers and through either bilateral contracts or public capacity auctions to the traders. A significant part of primary purchases of traders goes through a secondary trade within the trading sector before reaching final customers or export markets." (HEA)

In 2018, 11.597 TWh electricity has been sold within the universal service for eligible customers (10,97 TWh household customers and 0,627 TWh other) and 26.925 TWh was sold on the free market (99,8% non-household customers). There have been in total 5.324.618 customers in the universal service (thereof 5.108.411 household customers) and 259.533 customers on the free market (thereof 15.401 household customers).

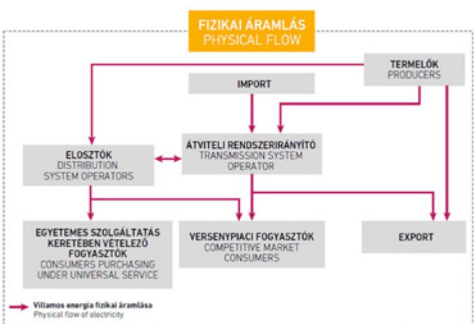
[15] MVM Paks II. Nuclear Power Plant Development Private Company Limited by Shares
[16] Joint-Stock Company Nizhny Novgorod Engineering Company Atomenergoproekt

The universal suppliers of the Hungarian electricity market are E.ON Energiakereskedelmi Kft., (a subsidiary of E.On Group) ELMŰ-ÉMÁSZ Energiaszolgáltató Zrt. (a subsidiary of Innogy) and NKM Áramszolgáltató Zrt. (a subsidiary of the NKM Nemzeti Közművek Zrt, a subsidiary of the state owned MVM Group). These universal suppliers (and DSOs) operate at different, non-overlapping geographic areas of the country. In 2018, there were 150 licensed traders in Hungary, out of which 99 were active. The HHI competition index of the sales on the free market was 1357 in 2018.

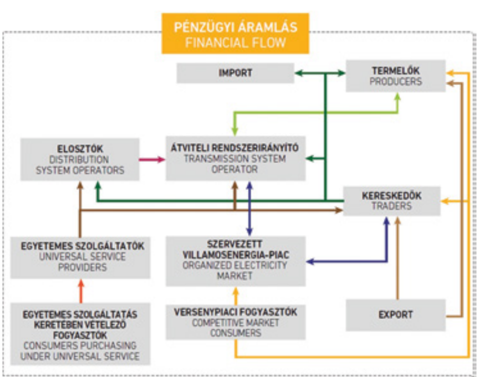
The model of the Hungarian electricity market is presented in Figures 5.151, 5.152, 5.153.

Figure 5.151 **Operating Model of the Hungarian Electricity Market**



Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018)

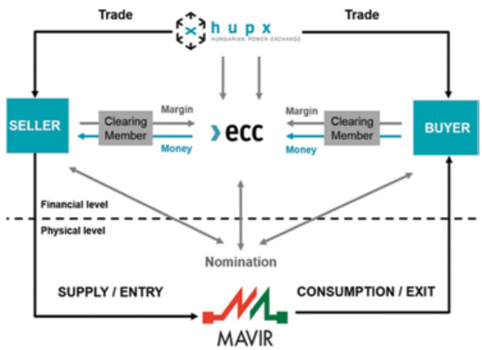
Figure 5.152 **Financial Flow of the Hungarian Electricity Market**



Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018)

The Hungarian Power Exchange HUPX Ltd is the organized electricity market providing trading with day-ahead and intraday contracts. Total traded volume on the day-ahead market reached 22.243 TWh in 2019, an 11,7% increase compared to the 19,98 TWh traded in 2018. The total traded volume on the intraday market reached 0,156 TWh, which is nearly three times higher compared to the 0,055TWh traded in 2018. Currently, there are 59 day-ahead market members and 36 intraday market members.

Figure 5.153 **Model of the Hungarian Electricity Market**



Source: HUPX Group Brochure 2020 - Energy Business Motion

The Hungarian Derivative Energy Exchange - HUDEX Energy Exchange Ltd., is a member of the HUPX Group and electricity futures contracts are available, with a market maker.

MAVIR prepares each year the National Ten-Year Network Development Plan (NDP), where it summarizes the necessary grid developments under different future load scenarios until 2034 (2019 edition) in the following categories: development of the transmission system; connection of power plants; development of the distribution system.

There are also three Projects of Common Interest (PCI) selected in line with the TEN-E Regulation in Hungary, which are the 3.17 Interconnection Hungary - Slovakia between Sajóivánka (HU) and Rimavská Sobota (SK); the 3.16.1 Interconnection Hungary - Slovakia between Gabcikovo (SK) and Gönyű (HU) and Velký Dur (SK) and the 10.7 Danube InGrid project (Hungary, Slovakia) -enhancing cross-border coordination of electricity network management, with focus on smart data collection and exchange.

(e) Renewables

"The trade of electricity generated from renewable resources and waste falls in a special trading category. This kind of electricity has to be purchased from generators by the transmission system operator (MAVIR Zrt.) under the feed-in tariff (FiT) scheme (at a price specified in the respective legislation and in volumes and during a period defined by HEA). MAVIR Zrt. sells the electricity purchased in the framework of FiT and the corresponding balancing energy to the traders, and another part in the organized electricity market." (HEA) Most of the currently installed renewable generation capacity is supported under a Feed-in Tariff (FiT) regime (Kötelező Átvétel - KÁT).

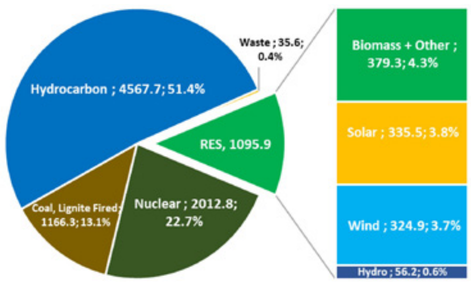
This system supports power plants with an installed capacity of 50-500 kW. "The FiT system was replaced by the so-called METÁR [Megujuló Támogatási Rendszer - Renewable Support System] system as of 1 January 2017 (i.e. applications can no longer be submitted, but the already granted FiT entitlements remain in force), which includes a new feed-in tariff system (METAR-FiT) up to 0.5 MW installed capacity, a "green premium without tendering" system for installed capacity between 0.5-1 MW and a "green premium granted through tendering" system for installed capacity over 1 MW." (Wolff Theiss)

"Under the FiT system, the generated electricity is sold to the TSO at a fixed price, whereas under the new METAR system the electricity is sold directly to traders or on the stock market with price correction. The HEA is the central agency for the FiT and METAR systems.

The FiT price, the supported quantity, and the support period, as well as the margin of METAR price correction are all defined by the HEA. The results of the solar boom in 2016, generated by the highly favorable and easily accessible FiT system, became visible in 2018, as the electricity generated by solar power plants increased by seventy-five percent (75%) compared to the previous year. Until the end of 2018 [2019], approximately 726 MW [958 MW] of solar power plants were put into operation." (Wolff Theiss)

In 2018, renewable-based generation capacities represented 12,34% of the total domestic installed electricity capacity. Due to the differences in the load factors of -especially weather-dependent- renewables, renewable technologies represented a slightly lower, 11,7% of gross annual power generation in 2018 (10,9% in 2017).

Figure 5.154 **Hungary's Power Generation Mix in terms of installed capacity (MW;%)**



Source: HEA - MAVIR - Data of the Hungarian Electricity System 2018

Solar Energy

The National Energy and Climate Plan (NECP) foresees increasing the installed solar capacities to 6.500 MW by 2030[17] and potentially to 10.000 MW by 2040.

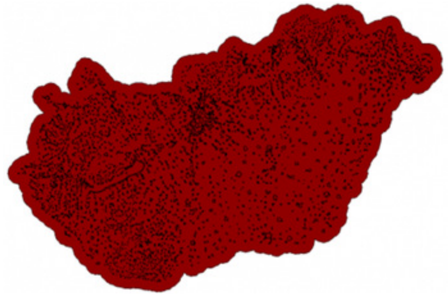
Wind Energy

Installing non-residential wind power plants is not outright forbidden, but such PPTs cannot be built inside or within 12 km from land for construction purposes[18].

17 The National Energy Strategy 2030 document foresees 6,000 MW
18 253/1997. (XII. 20.) - Government Decree

The following map illustrates (white area), where wind power plants can be constructed.

Map 5.46 **Designated areas for wind farm installations**



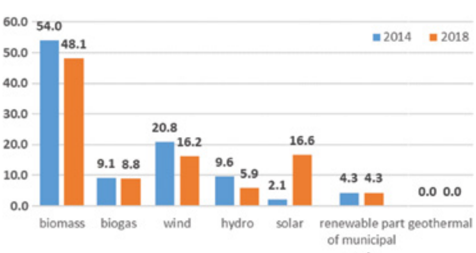
Source: Energiaklub - Szabad, csak nem lehet article [19]

Biomass and Waste

The share of renewable energy sources and waste in electricity consumption increased slightly (+ 0,7%) between 2014 and 2018.

Biomass dominates the renewable power generation in Hungary with almost half of the RES generation in 2018, however the share of solar generation already increased significantly, reaching 16,6% of RES generation in 2018; this increase is expected to continue due to the newly installed solar capacities (ca. 330MW end of 2017 vs. ca. 1.400 MW end of 2019 including household and commercial plants) which is expected to increase the share of RES generation as well.

Figure 5.155 **Share of renewable resources and waste in electricity consumption (2014 vs 2018) [%]**



Source: KSH/CSOH 5.7.3. Share of renewable resources and waste in electricity consumption (2000-) [%]; own elaboration

Geothermal Energy

Hungary has above average geothermal energy potential. The average geothermal gradient in Europe is 30-33°C/km, in Hungary it is 42-45°C/km, but can also reach 100°C/km at specific locations. The Hungarian geology is better suited for heat generation instead of electricity generation. In Iceland, the value can reach above 300°C/km in certain locations[20]. which is better suited for electricity generation. In 2018, primary production of geothermal heat was 140,1 ktoe: 54,69% of this heat (76,6 ktoe) is used for electricity (10,1 ktoe) and heat generation (66,5 ktoe) as transformation input. 28,3% (39,6 ktoe) was directly used by the agricultural and forestry sectors, whereas 15,58% (21,8 ktoe) was used by the commercial and public services sectors.

In 2018 15,57% of Hungary's housing stock was connected to district heating. The total number of consumers (households and others) were 679.187. In 2018, geothermal energy represented ca. 6,7% (54,7 ktoe) of total district heat production (811,5 ktoe)

The first geothermal power plant to produce electricity is a CHPP that produces 3 MWs of clean electricity and 7 MWth of geothermal heat for house heating and is located in Tura. The Energy Strategy foresees a higher utilization of the geothermal potential.

Hydroelectricity

There are two run-off river hydro power plants in Hungary on the river Tisza with a combined capacity of 41,7 MW. Additionally, there are some micro hydro power plants, which add up in total to 56,2 MW. There is additional hydro potential in Hungary, especially on the Danube and Drava rivers. However, since the stoppage of construction works of the Gabčíkovo-Nagymaros barrage system on the Hungarian side in 1989 due to environmental concerns and following termination of the contract with Czechoslovakia about the joint construction project in 1992, the unilateral commissioning

of the existing version on the Czechoslovak (today Slovakia) side, and the ensuing years of litigation, the topic has been politically charged and has not been widely discussed.

(f) Energy Efficiency and Cogeneration

Energy Efficiency

The goals for energy efficiency improvements in the National Energy 2030 document include decarbonization and decrease of import needs - along with keeping competitive end-user prices. One of the most important practical actions of the energy policy making is the application of "energy-efficiency first" principle[21] in infrastructure planning, policy making and investment decision making.

According to the Eurostat's energy balance, the primary energy consumption in 2018 was 24.489 ktoe. After transformation, transfer, and distribution losses, disregarding non-energy use, 18.543 ktoe got to the final consumers - final energy consumption, representing 75,72% of primary energy consumption. Primary energy consumption was 23.298 ktoe in 2015, (implicating a 5,1% increase in three years), whereas the final energy consumption was 17.400 ktoe (implicating a 6,5% increase in three years), represented 74,7% of the primary energy consumption. The above numbers imply increasing energy consumption, but also faster energy-efficiency improvements.

The goal of the Energy Strategy is that final energy consumption in 2030 shall not exceed the 2005 value of 18,7 Mtoe and any increase beyond 2030 shall be supplied from carbon neutral energy sources. The cumulated final energy consumption saving goal for the 2021-2030 period[22] is 7,9 Mtoe which would be a linear 0,8% saving, meaning an additional 167 ktoe per year.

The energy efficiency programs introduced between 2014-2020 would result in 72-96 ktoe baseline savings each year, thus, to achieve the target, it is necessary to increase the annual savings by approximately 300%. The strategy aims to achieve this goal via the energy efficiency obligation scheme[23], where energy distributors and retail energy sales companies are obliged to achieve cumulative end-use energy savings. In comparison with the neighboring countries, the household energy use, especially energy used for heating and cooling is relatively high. Presumably, the obligated parties can achieve energy savings the easiest in this area. The European Union goal[24] of having a highly energy efficient and CO_2 neutral building stock by 2050 shall also be observed.

The Széchenyi 2020 Program coordinates the allocation of funds[25] available from the Europe 2020 Program for Hungary between the 2014-2020 period. Each country prepares the so-called Operative Programs[26], which define the thematic areas where the funds can be utilized, in line with the pre-defined policy goals[27].

[21] In line with REGULATION (EU) 2018/1999 OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 11 December [21] 2018 on the Governance of the Energy Union and Climate Action
[22] in line with the Eurostat 2020-2030 SDG indicators methodology.
[23] Art.7. of the DIRECTIVE 2012/27/EU OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 25 October 2012 on energy efficiency, amending Directives 2009/125/EC and 2010/30/EU and repealing Directives 2004/8/EC and 2006/32/EC
[24] Energy Performance of Buildings Directive 2010/31/EU (EPBD) and the Energy Efficiency Directive 2012/27/EU

[26] https://ec.europa.eu/regional_policy/en/atlas/programmes/
[27] https://ec.europa.eu/eu2020/pdf/COMPLET%20EN%20BARROSO%20%20%20007%20-%20Europe%202020%20-%20EN%20version.pdf

Programs for energy efficiency are available among different operative programs, but most of the dedicated funds are assigned via the Environmental and Energy Efficiency OP[28](KEHOP), the Economic Development and Innovation Operational Program (GINOP)[29] Territorial and settlement development OP (TOP) and the Competitive Central-Hungary OP (VEKOP).

Each Operative Program defines priorities, within which tenders are published for actions to be supported.Such actions within the KEHOP include: *Building energetics development of public buildings*[30] or the Energy efficiency investments of budgetary institutions[31]; while through the GINOP another program concerns: *Credit aiming at increasing of energy efficiency and renewable energy use of residential buildings*[32] or *Support for building energetics developments aiming at increasing renewable energy use and energy efficiency*[33] [for SMEs].

The government's "Warmth of Home" program, aiming at supporting physical persons has, in recent years, featured programs for improving the energy performance of buildings and related renovation of condominiums and household appliance swap campaigns or heating modernization. Additionally, based on the corporate tax law[34], there is tax reduction available for companies' investments aiming at increasing the energy efficiency of their operations.

Apart from the above described support schemes the government aims at introducing more stringent building regulations. As of 1 January 2021[35], all new buildings (with specific exceptions and certain new public buildings even earlier) and various large renovations shall comply with the BB - Nearly zero-energy buildings (NZEB) standard[36].

Cogeneration

The work environment for cogeneration operators fundamentally changed in 2011, when the FiT scheme to support energy-efficient CHP introduced in 2002- was abolished, to re-focus on the support system for renewable technologies. After this energy policy shift, CHP producers had to re-evaluate their business models in order to compensate for the lost cashflow; some have closed or paused operations, others have formed regulatory centers, where they offer their flexibility to the TSO as a virtual power plant. On the output side, the heat has a regulated price, set each year before the heating season by HEA.

In 2018, according to the Eurostat energy balance, 16,6% of the gross electricity production was generated by main activity producer CHPs and autoproducer CHPs (ca[37]. 19,8% in 2010). If corrected by the autoproducers and the heat produced by the nuclear power plant, the share is 13,9% (18.8% in 2010).

[33] GINOP4.1.4-19 - Megújuló energia használatát, energiahatékonyság növelését célzó épületenergetikai fejlesztések támogatása - ca. 60m EUR
[34] Para. 22/E 1996. évi LXXXI. törvény a társasági adóról és az osztalékadóról
[35] 7/2006. (V. 24.) TNM rendelet az épületek energetikai jellemzőinek meghatározásáról
[36] Directive 2010/31/EU of the European Parliament and of the Council of 19 May 2010 on the energy performance of buildings
[37] NPP was considered as Main activity produced CHP in the statistics until 2016. Since 2017, a minor share of the generated electricity is registered as Main activity produced CHP, whereas most of the electricity production is registered as Main activity producer electricity only.

The National Energy Strategy 2030 foresees potential investment support for CHP generators which are integrated into the district heating system, especially since the increased winter production optimally supplements the higher photovoltaic production during the summer. Providing heat storage subvention, or eventually FiT-type support during the heating season to very efficiently operating CHP generators is also being considered.

Energy Investment Outlook

The ongoing energy investments have been partially described in the sectoral overviews. In this section, the expected and probable investments are summarized, where reference data and estimated costs are available.

Energy Infrastructure

In the power generation sector three major areas are expected where investments are already happening or are expected until 2030.
The Paks II Nuclear Power Plant is currently under permitting, nevertheless the construction of some service facilities has been tendered, awarded and started to. The cost of the project is estimated by the National Energy Strategy 2030 document to be around 12 bn EUR (4,000 bn HUF). The project will possibly be commissioned by the early 2030s, although no official target date has been published. The CAPEX estimates for the different proposed investments in the power grid under various scenarios of the National Ten-Year Network Development Plan are not published.

Nevertheless, a summary of necessary transmission system developments has been prepared by Energiaklub[38] in 2017, based on the scenarios of the previous energy strategy document.

The paper examines the grid development needs until 2030 in four categories:

• developments necessary to ensure security of supply to consumers	200-220 mEUR
• developments necessary to connect new power plants	45-130[39] mEUR
• cross-border developments[40]	61[41] mEUR
• developments necessary on the distribution system	2,250[42] mEUR

According to the energy strategy, the installed solar photometric capacities should reach 6 GW by 2030. Knowing that the installed capacity of commercial and household PVs reached 1,400 MW by the end of 2019, and assuming that 500MW more will have been built by the end of 2020, some 4,100 MW of new solar capacity can be expected to be installed until 2030. Assuming that the household to commercial share will be 20 to 80, and 0,5 MW[43]PPT's turnkey CAPEX[44] is 450,000 EUR (153 mHUF), and a household system's turnkey CAPEX is 1 EUR/Wp, the anticipated total investment until 2030 is ca. 3,8 bn EUR (840 mEUR household + 2,952 mEUR commercial PPT). Proposed projects on the gas transmission grid are available in the TSO's national TYNDP 2019 consultation document[45] without estimated CAPEX.

[38] Grid Development Needs in Hungary - Hálózatfejlesztési igények Magyarországon https://www.energiaklub.hu/files/study/Energiaklub_Bixpert_H%C3%A1l%C3%B3zatfejleszt%C3%A9si%20tanulm%C3%A1ny.pdf
[39] Included power plant projects have partially changed but other project ideas have emerged
[40] 750/400KV transformation and expansion of SK interconnection capacity
[41] ENTSO-E TYNDP references 81.63 mEUR for the HU-SK project CAPEX. Assuming 50% for Hungary and keeping the cost of the 750/400KV transformation at 20m EUR.
[42] Corrected compared to the figure in the text. Based on the analysis of annual DSO CAPEX/yr being 250 mill EUR/yr referenced in the text, extrapolated for the 2021-2030 period
[43] 600kWp nominal DC capacity with 500kW AC connection capacity, without the cost of the land including project development costs and assuming "close" connection possibility to DSO network
[44] Nominal, constant price with 340 HUF/EUR exchange rate
[45] https://fgsz.hu/file/documents/1/1528/2019_12_03_10_eves_fj_nyilvanos_konzultacio.pdf

Some of the cross-border projects are also available in the ENTSOG TYNDP 2020[46] document, with alternative CAPEX estimates. Capacity Auction and Open Season rulebook documents of FGSZ do provide CAPEX estimates or Present Value conditions to be met.

The projects which can potentially be realized by 2030 include:

- Enhancement and Development of the HU-SK interconnector (58,6 mEUR)[47]
- Hungary-Slovenia Interconnection (205 mEUR) [48]
- Compressor Station at Városföld town (20 mEUR) [49]
- Hungary-Ukraine development from interruptible to firm capacity [50] (N/A; max 10 mEUR)
- New Serbia-Hungary Interconnector [51] two versions (48/164 mEUR)
- Romanian-Hungarian reverse flow Hungarian section 2nd stage[52] (235 mEUR)
- Hungary-Austria Reverse Flow [53] (233,6 mEUR)

FGSZ has recently spent annually some 10-20 mEUR CAPEX per year, do without major project implementation[54]. The uncertainty at this stage is very high as to which projects will actually materialize, consequently, the final investment in the gas transmission system could potentially be anywhere between 158 mEUR[55] and 1154 mEUR[56] in the 2021-2030 time horizon.

The National Energy Strategy 2030 document foresees the entrance of new gas-based power generation capacities until 2030, partially to replace the lignite-based generation of the Mátra PPT. Additionally, existing CCGT capacities should be refurbished to increase their operational efficiency and prolong their life-span. For simplicity, two scenarios are considered; one where 500 MW new CCGT capacity enters the market, and another one where 1,000 MW new CCGT capacity enters the market. CAPEX of 1 MW of CCGT capacity is assumed to be 1,076 EUR/kW[57] . With these assumptions, the potential CAPEX is between 538 mEUR and 1,076 mEUR.

Energy Efficiency

With regards to energy efficiency investments, the new Green Bond Framework of Hungary referenced 23 bnHUF (ca 68 mEUR) state expenditure for Energy Efficiency in the 2018-2021 timeframe[58].Assuming doubling the annual expenditure for the 2022-2030 period, in total ca. 320 mEUR (109.25 bn HUF) state expenditure is expected in the 2021-2030 horizon for energy efficiency improvements and green buildings[59].

[47] ENTSOG estimate alternative CAPEX
[48] ENTSOG estimate alternative CAPEX
[49] ENTSOG estimate alternative CAPEX
[50] no CAPEX available but the necessary investments represent relatively low CAPEX of maximum 10 mEUR
[51] Prolongation of TurkStream and Gastrans (Serbia) pipeline projects to Hungary
[52] O/S failed, a successful O/S for the project would be needed, in case the Romanian Black See gas potential is developed
[53] Successful O/S for the HU>AT project and
[54] Based on Annual Reports of FGSZ - https://fgsz.hu/en/transparency-information/reports-and-announcement
[55] Assuming that the Városföld CS, SR-HU stage I and HU-UA firm projects will at least be realized until 2030, along with the 10 mEUR CAPEX/yr.
[56] All projects are realized along with 20 mEUR CAPEX from 2021 to 2030 which is highly improbable.
[57] Projected Cost of Generating Electricity - 2015, IEA Table 3.2 Hungary - adjusted for 2025 prices. Exchange rate is assumed at 1,1 USD/EUR
[58] https://www.akk.hu/en/page/green-bond
[59] Subsidies to purchase energy-efficient electrical appliances (Home Warming Program) - Public building renovation - Support to farm owners and local institutions to implement energy efficiency measures - Subsidies to SMEs focusing on energy efficiency solutions

Simply assuming a 100% multiplicator (50% support intensity), the total, nation/wide energy efficiency investment generated by this state expenditure would be ca. 640 mEUR until 2030. This figure does not include private investments independent from the above state program. An Electric Vehicle support scheme was introduced in 2016.

Currently 5 bnHUF (14.1 mEUR) is available for fully electric vehicles, electric taxis, and electric mopeds within the ongoing scheme. Maximum support intensity is 2.5 mHUF (ca. 7350 EUR per vehicle)[60].

Assuming that the annual 14.1 mEUR remains available each year through 2021-2030, a total of 141 mEUR can be handed out between 2021 and 2030, realising ca. 560 mEUR investment in electric vehicles (ca. 19,000 cars).

The Climate and Nature Protection Action Plan 2020[61] document foresees the installation of one million electric smart meters by 2030. Assuming 100 EUR wholesale cost per meter, this plan results in a country/wide investment of 100 mEUR.

The Green Bus Program in the Action Plan foresees that only electric buses can be procured in cities with a population over 25.000 from 2022 onwards. The proposed budget for this program is ca 105 mEUR until 2030.

The National Energy Strategy 2030 Document estimates that, in order to reach the 2030 energy and climate goals, additional investments should reach 44.5 bn EUR until 2030, without the Paks II NPP.

[60] For vehicles costing max 11 mHUF ca 32,350 EUR.

ISRAEL

Israel

Economic and Political Background

Activity softened in the fourth quarter of 2020, with GDP expanding 6.3% in seasonally-adjusted annualized rate (SAAR) terms (Q3: +41.5% SAAR). However, the economy performed fairly well relative to other developed economies in the period and shrank a mere 2.3% over 2020 as a whole (2019: +3.4% y-o-y). Resilience in Q4 was likely due to firms being better adapted to restrictions and more able to shift their activity online, as well as citizens' reduced compliance with measures.

Private consumption increased 18.2% in the fourth quarter, which was below the third quarter's 42.2% expansion, likely weighed on by the second lockdown early in the quarter. Government spending grew at the fastest rate on record, expanding 26.0% (Q3: +8.5% SAAR). Meanwhile, fixed investment growth improved to 66.1% in Q4, up from the 17.4% expansion in the prior quarter and driven by surging industrial investment.

Exports of goods and services fell 4.9% on a SAAR basis in the fourth quarter, which contrasted the third quarter's 67.6% expansion. Conversely, imports of goods and services bounced back, growing 88.5% in Q4 (Q3: -1.3% SAAR). The reading was driven by surging car imports amid frontloading ahead of tax hikes at the start of 2021.

On an annual basis, GDP declined 1.3% in Q4, down from the previous quarter's 1.2% decrease.

Looking ahead, activity in the early part of Q1 will likely be held back by the third lockdown. However, the country's record-beating vaccination pace has allowed a relaxation of restrictions from early February, which, coupled with recoveries abroad, should spur momentum through the rest of the year. IMF estimates that Israel's GDP will expand by 4.9% in 2021, significantly higher than -5.9% in 2020. On April 20, 2021, Prime Minister Benjamin Netanyahu called for direct polls to choose Israel's next leader, as he struggles to form a coalition following four general elections in less than two years. Netanyahu's rightwing Likud won 30 seats in elections held in March, making his party the largest in Israel's 120-seat parliament. He has support from ultra-Orthodox parties and an alliance of hardline nationalist factions, but has not been able to cobble together a 61-seat majority. Challengers to Netanyahu, including Yair Lapid of the centrist Yesh Atid party, are waiting in the wings to form a government to replace Israel's longest-serving leader, who has been in office for 12 consecutive years.

Energy Policy

National Energy Policy - Country's energy policy, its objectives and strategy

Over the last two years, Israel's energy policy has been focused mainly on reducing the emissions of pollution and GHG in the power sector, because this is the sector which is the easiest to have the greatest impact. A second goal has been to increase competition, in both the power and natural gas markets through the introduction of the private sector, as well as to reduce prices in both these markets.

Since Israel has large volumes of natural gas (1,000 bcm discovered to date in a market which consumes 11.5 bcm a year in 2019), the government's goal is to reach more than 80% natural gas and 17% renewable energy in the power sector by 2030 and minimum coal usage. In November 2019, the Ministry of Energy, under pressure, stated that the renewable target will be revised and may increase to 25%-30% by 2030 and zero coal generation already by 2025. These targets however are ambitious and not yet backed by a government decision.
Thus, a strong trend in Israel with special emphasis at the end of 2019 is to increase renewable energy, with special focus on solar PV (with two existing thermal power station, at the Ashalim station).

The transition to natural gas in the Israeli economy between 2013-2018 has led to a 62% reduction in SOX and 50% reduction in NOX emissions. Between 2013 and 2018, the emission of these pollutants declined by 62% and 50% respectively. The decline in emission of sulphur oxide and nitrogen dioxide has saved the Israeli economy $4 billion during this period (Gas Forum).

On the transportation front, statements have been made by which as of 2030 only new electric or gas operated vehicles (CNG) will be able to be imported into Israel. Yet again, although the country is making the first initial steps to establish CNG refueling stations and electricity recharging points, this infrastructure is still in the initial stages of development. The barriers to electric vehicles stem from the fact that the state does not have a detailed master plan for the energy market, only sporadic decisions whose validity is unclear. As a result, Israel lacks comprehensive regulation for automakers, charging station owners and consumers, as well as specific assignments for IEC so it can expand its systems to deal with the sharp spikes in electricity demands. Another issue will be the need for the treasury to find alternative source of revenue for the 18 billion NIS in annual revenues from the gasoline excise tax (over $5 billion).

Competition in the natural gas market will break-through as of January 2020, as the 610 bcm Leviathan gas field starts commercial production (1st gas flowed on 31.12.2019) and will increase to three independent gas suppliers by by mid-2022 as the Greek-British company's Energean's Karish field comes online. In this respect, Israel will have 3 independent and separate gas pipelines coming onshore into Israel with a capacity to supply c-30 bcm a year, by mid-2021, plus an FSRU to import LNG in case of emergency or for spot needs. Aw a result of the competition, the Israel;i IPP's and industrial consumers enjoy longterm contracts with stable prices around $4/mmbtu even during the peak of the energy crisis while European countries pay even 10 times higher.
In the power sector, competition is increasing also, with private power producers generating over 30% of the electricity generation by the end of 2018, with this figure growing fast as the state-owned utility (IEC) is to sell 5 power stations containing 19 power generation units over the next 5 years to the private sector. The main sector, however, is indeed the country's natural gas market and between 2013 (when the Tamar field came on line) and until the end of 2018, natural gas has saved over $17 billion in energy costs.

Governmental institutions

Key institutions and their role in policy making.

The main governmental institutions that relate to energy are the Ministry of Energy which now includes also the two main regulators – The

Natural Gas Authority as the gas regulator – and the Public Utility Authority (Electricity) which is the electricity regulator; the Ministry of Finance and the Ministry of Environmental Protection. Two other important government owned companies are Israel Electric Corporation (IEC) which is the main electricity utility company and Israel Natural Gas Lines (INGL) which is the monopoly natural gas transmission system operator.

Ministry of Energy – The Ministry of Energy is responsible for all of Israel's energy sectors and its natural resources, including electricity, fuel, LPG, natural gas, conservation of energy, water, sewage, petroleum explorations, minerals, earth science, marine research and more. The Ministry supervises the public and private bodies operating in these fields, while regulating the market, protecting the consumer, and protecting the environment.

Ministry of Finance – The Ministry of Finance is, inter alia, responsible for determining and implementing economic policy in Israel. In this respect it is the entity that greatly determines and provides budgets for energy related issues that range from reform in the electricity sector, to grants for the deployment of natural gas distribution pipelines, as well as for R&D in energy novelty.

Public Utility Authority (PUA) – In 1996, the Israeli Electricity Market Regulatory Authority was established, with the objective to, inter alia, balance between maintenance of a fair rate framework to be imposed upon electricity consumers, and support of private power plants, as well as determining electricity tariffs in a competitive and equitable manner.

Natural Gas Authority (NGA) – Was established in 2004 by virtue of the Natural Gas Sector Law 2002, and is the regulator that promotes long-term strategic planning, grants licenses and supervises the licensees in the natural gas mid- downstream segments, sets tariffs and standards for the provision of services, clarifies disagreements and determines arrangements between the players in the market, and handles consumers' complaints.

Ministry of Environmental Protection – Insofar as energy is concerned, its focus is on the reduction of greenhouse gas emissions, financial incentives that encourage greenhouse gas reduction and promoting the decreasing consumption of electricity and the use of renewable energies.

Israel Electricity Corporation (IEC) – IEC is owned by the State of Israel (99.8%). Its activities include the generation, transmission and transformation, distribution, supply and sale of electricity. IEC owns and operates 17 power stations with 61 generating units.

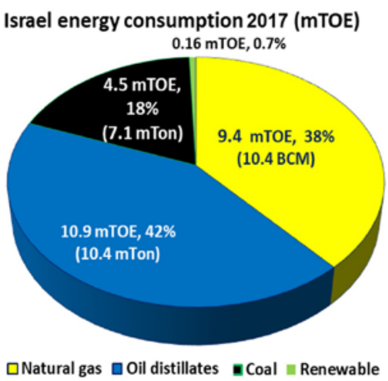
Israel Natural Gas Transmission (INGL) – The national transmission network of Israel Natural Gas Lines is the main artery for natural gas transmission in Israel. The network includes the western, central, northern and southern trunk lines, totaling 750 km and there are plans underway to further develop and expand the network.

Energy Demand and Supply

Israel's energy (2018) is based 42% on oil, 38% on natural gas, 18% on coal and only 1% renewable generation (2.9% actual renewable generation in power sector). These figures, however, are due to change as coal becomes phased out and is replaced gradually by natural gas and renewables. In terms of renewables, the main real source of supply is solar with minimum wind facility, although one hurdles has been removed recently in the form of opposition from the Ministry of Defence. Israel has no hydro or geothermal power. Israel also has no nuclear power and no plans to construct any nuclear power stations in the near future.

In terms of natural gas consumption, demand for gas has hitherto been restricted by the lack of availability of supplies to grow in line with demand, so that consumption will reach 11.2 bcm a year in 2019 (full year), comprised mainly of gas from the local Tamar field and c-0.7 bcm of LNG imports. As of 2020, however, with the start of commercial production from the Leviathan field, consumption will be able to grow organically based on demand (see graphs below). In addition to the electricity sector, natural gas is the primary energy source for Israeli industry connected to gas transmission infrastructure. For now, the use of natural gas in small- and medium-sized industrial plants is still in its early stages, whilst residential, commercial and gas in transportation has not yet really taken off, partially due to the still limited scope of development of the low-pressure, privately owned, distribution networks, albeit CNG is starting to be used in transportation in Israel. The first inroads of natural gas and electricity in the transportation sector, was facilitated thanks to supportive governmental regulations and policies, directed towards ceasing to use oil and to transition to natural gas and electricity for transportation. The government's goal is that in the industrial sector, 95% of the energy and steam required will be generated from natural gas as of 2030. Although Israel has a lot of energy in the form of natural gas, Israel has hitherto only achieved just over 40% energy independence. The objective in the next few years is that more than 50% of the energy will be locally produced (increase use of natural gas and renewables and reduced coal imports and use in power generation and liquid fuels in transportation).

Figure 5.159 **Israel's total Energy Consumption and Electricity Generation in 2017**



Electricity Generation - 2017	
Total:	68,309 million KW/h
Gas:	43,837 million KW/h
Of that IPP (mostly gas):	17,735 million KW/h
Coal:	22,052 million KW/h
Renewables:	1,786 million KW/h

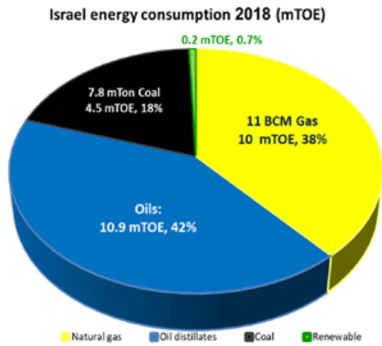
Figure 5.160 **Israel's total Energy Consumption and Electricity Generation in 2018**



Electricity Generation - 2018	
Total:	69,644 million KW/h
Gas:	46,767 million KW/h
Of that IPP (mostly gas):	19,701 million KW/h
Coal:	22,599 million KW/h
Renewables:	2,038 million KW/h

Source: Israel's Ministry of Energy

Oil and Petroleum Productions

In 2018, Israel imported about 100 million barrels of oil, out of which it consumed 79 million barrels. The remainder was re-exported mostly as heavy fuel oil. Most of the oil is imported from Azerbaijan via the BTC pipeline, plus some spot supplies from other countries. Most of the exports are to the Mediterreanan region and Africa.

Israel is 98% dependent on imports for its crude oil, with the remaining 2% stemming from condensates produced from the natural gas fields and a small onshore oil field. Insofar as distilliates are concerned, Israel is mostly independent, with some imports of LPG.

Israel is mostly dependent on imports of oil since it has minimal reserves and exploration in this respect. The country however preserves emergency reserves of crude oil and distillates

Table 5.123 **Distillates consumption 2015-2018**

consumptions of distillates in thousands of tons

Source: Israel's Ministry of Energy

Israel has two oil refineries, the biggest one being the Bazan refinery in Haifa with a 9.8mn t/y capacity (197,000 b/d) and the Paz Baza refinery in Ashdod with a 5mn t/y capacity (100,000 b/d). The main new projects planned in this respect relate to the closure of the main Haifa refinery and the establishment of a more modern facility in a more remote area of the country. This is a long-term plan which if realized will take at least a decade to accomplish.

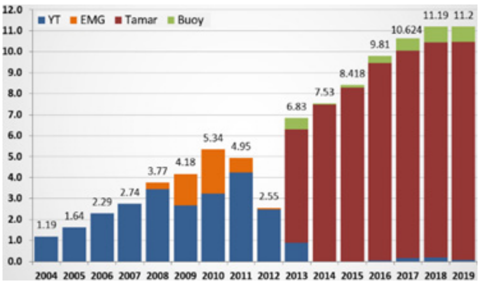
Natural Gas

- Gas consumption in 2018 (including exports) totalled 11.11 BCM – a 7% increase from 2017; the volume is anticipated to be the same in 2019.
- 95% of the gas (10.44 BCM) was supplied by Tamar and the remaining 0.67 BCM was imported as LNG via an FSRU.
- Gas consumption by the industry rose by 12% compared with 2017 to 2.02 BCM, following the connection of new consumers to the distribution network.
- Since April 2013, with the start of supply from Tamar and construction of the LNG buoy, gas consumption in Israel has grown by 63%.
- As of the end of 2018, five large conventional IPPs and five factories (cogeneration facilities) are connected to the gas transmission system in addition to IEC's stations.
- 15 large industrial consumers have been connected to the transmission system, 69 consumers have been connected to the distribution network (11 in 2018) and 7 consumers consume CNG supplied by trucks.
- Distribution network and LPG consumers consumed a total of 0.24 BCM in 2018, a 21% increase from 0.2 BCM in 2017. In 2019, distribution network and LPG consumers are due to consume more than 0.3 BCM. 90% of these consumers are located in the south.
- As of end 2018, INGL (high pressure transmission system) has constructed about 750 km of transmission lines whilst the low pressure distribution pipelines total 350 km.
- The total saving for the market from the transition to gas between 2004 and the end of 2018 is estimated at 63.7 billion NIS, 49 billion of which is in the electricity sector; Gas consumption has saved the Israeli industry 14.7 billion NIS.
- Between 2004 and the end of 2018, 83 BCM of gas were supplied in place of coal and distillates.
- The highest daily consumption rate in 2018 was recorded on 15.7.2018 and totalled 37,202 CM; An hourly record of 1,762 CM (63,395 MMBTU) was on 28.1.2018. The maximum hourly supply from Tamar in 2018 was on 9.7.2018 at 9:00 and reached 1,353 MCM (48,684 MMBTU). The maximum hourly supply capacity from Tamar is 49,500 MMBTU.
- The average hourly and daily flow rates were 9 MCM and 28.6 MCM, respectively.
- 0.67 BCM were supplied from the LNG buoy in 2018 compared with 0.52 BCM in 2017, mainly during the summer.
- The Ministry of Energy collected 860 million NIS in royalties on gas during 2018.
- Leviathan's development has been completed and is in full commercial operation since 1.1.2020.
- Energean remains on track to deliver first gas from the 1.4 TCF Karish development project in mid-2022. At 30 September 2021, the project was approximately 91.8% complete. The "Energean Power" FPSO will be the first gas FPSO ever to have operated in the Mediterranean, and is expected to leave the yard in Singapore for Israel in 1Q 2022. This journey will take around 35 days. Hook-up and pre-first gas commissioning will then take approximately three months.
- In May 2018, the Ministry of Energy published a tender to accelerate the deployment of the distribution network which includes three parts: long-term loans for building lines;

long-term loans for increasing throughput; and long-term loans for building pressure reduction stations. The budget for the first round is 200 million NIS.

- The Ministry published a tender for CNG fuelling stations in the amount of 100 million NIS; and a tender for connecting distant gas consumers in the amount of 50 million NIS.

Figure 5.161 **Gas Supply 2004-2019**



Source: Delek Drilling

Solid Fuels

The only use of solid fuels in Israel is of coal for electricity generation. Israel, however, does not have any coal production or deposits and all coal consumed is thus importer by Israel Electric Company (IEC). The main suppliers of coal are from south Africa, Colombia and Russia.

The use of coal has been sharply decreasing in Israel over the last few years, with the latest government goal to stop using coal on a regular basis by 2025-2026 and just preserve the coal stations' ability to generate with coal in case of emergency (preserve the use of dual fuel generation stations).

In 2018 (same figures anticipated for 2019), the consumption of coal was 7.8 million tons, producing 20.5 TW/h, 29.6% of total electricity generation. Coal consumption in 2017 was 8.2 million tons, in 2016: 9.1 million tons and in 2015: 10.7 million tons. All this compares to 14 million tons consumed in 2012 (63.4% of total electricity generation) prior to the commercial production of the Tamar field. Coal facilities today consist of 10 coal units (at 2 power station sites in Hadera and Ashkelon) with a total generation capacity of 4,840 MW, operating at an average load of 49%. The first phase target is to shut down 1,440 MW (4 out of the units) by June 2022, whilst the remaining 3,400 MW will be converted to dual-fuel with natural gas as the main fuel by 2025-26.

Electricity

In 2018, State owned Israel Electric Corporation (IEC) generated 68.7% of the electricity in the market (71% in 2017, 72% in 2016), IPPs thus generated 31.3%.

The total electricity consumption in Israel (including the Palestinian Territories) was 69,644 MW.

In 2018, IPPs were 26% of the installed capacity but generated 31% of the electricity (in 2017, IPPs were 24% of installed capacity and generated 29% of the electricity). Out of the IPPs, natural gas amounted to an installed capacity of 19%, whilst generating 28% of the market's electricity amounting to 19,700 MW. IEC has a total installed capacity of 13,335 MW. All of the electricity consumed in Israel is generated locally with no imports from oversees. In addition, Israel does not export any electricity to neighbouring countries. Thus, there are no cross-border interconnections and nothing in this respect is planned.

Israel has no nuclear or hydro power generation plants and nothing is planned in the near future in this respect. In terms of future plans, about 800 MWs of new CCGT and cogeneration (natural gas operated) power stations are due to come online within the next 18 months. In addition, 300 MW of pumped storage facilities are due to start operating in the next year.

The annual growth in electricity consumption in Israel has historically been over the last 20 years about 3%/p.a. However, since 2012 growth was reduced to 2.23%/p.a. and it is expected to remain at this level over the next few years. This is on a par with population growth of 2% per annum, but lower than the growth in GDP per capita which is about 3.5% per annum.

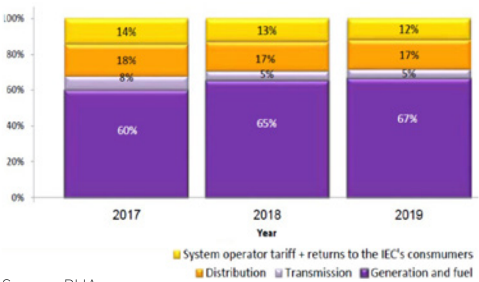
Electricity tariffs

All the various elements of the electricity tariffs (generation, connections, T&D, supply) are determined by the electricity regulator (PUA). Israeli electricity is priced in two ways: residential consumers ordinarily pay a "uniform tariff," which is currently 47 agorot/kWh (Dec 2019). Businesses and factories often pay a tariff that varies according to the season and hour, known as "time of use".

In January 2020, the domestic electricity tariff fell by 4.1% to 45.05 agorot/KWH (about $0.13). The main reasons for the fall is due to lower fuel prices (international coal prices, natural gas in the form of spot purchases from the Leviathan field), as well as revenues from the sale of the first IEC power station sold to the private sector as part of the reform in the electricity market.

Figure 5.163 **Tariff structure**



Source: PUA

Renewables

During 1926-1932 a renewable/hydro station (18 MW) was built on the Jordan river in the land of Israel (under the British mandate) and was the main power source for the country. The station was destroyed during the War of Independence (1948) and never renewed its operations.

In the 1950's, Israel was among the pioneer's countries to use thermo-solar panels to heat water, mainly for domestic use. To this day, most residential premises in the country are obliged to install thermo-solar panels.

Starting in 2009, the government initiated several programs to promote renewable energy: solar, wind and biomass, mainly by issuing tenders and setting attractive feed-in-tariffs.

Renewable capacity at the end of 2018 was 1,303 MW or 7.2%; in 2017 the renewable capacity was 946 MW, 5.3%. The Ministry of Environmental Protection and the Electricity Authority within the Ministry of Energy stated that by the end of 2019, renewable capacity would reach more than 2,000 MW and was expected to double again by the end of 2020.

In 2018, renewable energy generation amounted to 2,038 MW/h or only 2.9% of de facto total electricity generation. In 2017 the figure was 1,786 MW/h or 2.6% of total generation. The Ministry of Environmental Protection and the Electricity Authority stated that by the end of 2020 renewable energy generation would reach 10% of total generation.

The government targets in this respect were set in 2015, following the "Paris Climate Summit".

The government stated that "Renewable energy will supply 10% of electricity generation by 2020 and 17% of electricity generation by 2030". In November 2019, the Minister of Energy stated that the government is considering revising these national targets for 2030 to be 25-30% of electricity generation.
Renewable energy sources:

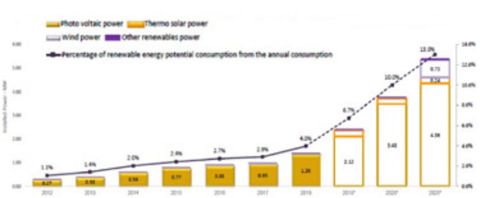
- Photovoltaic - Most of the existing (1,500 MW) and future renewable energy is solar PV.
- Thermo-solar - 2 existing power plants, 110 MW and 121 MW, operate at the Ashalim station.
- Wind – a 120 MW station is under construction in the Golan Heights and a number of other projects are being discussed. These encounter opposition from local citizens (NIMBY), environmentalist (destructive to birds) and the Ministry of Defence (impedes the air force's ability to manoeuvre).

- Hydro - Presently, Israel does not have classical hydro plants; however it is in advanced stages of constructing two pumped storage facilities for 300 MW and 340 MW respectively. A third such project is being discussed.
- Geothermal - Israel does not have geothermal energy.

The focus for the future expansion is on PV. Until 2-3 years ago, the high cost of such technology was the main obstacle for further expansion of PV. As the price of PV systems dropped sharply the main drawback for solar plants in Israel is now the amount of land it requires, an acute issue in a country of extreme high population density as is Israel. To reach a renewable/solar rate of 30% (and lacking most other renewable options besides PV), Israel needs to attain a PV capacity of 18,000 MWs. Such a scope requires a footprint of 180,000 dunams. Israel suffers from a shortage of open spaces, with such land only available in the far south, which would in turn require huge investment (and losses) to transmit the power to the main centres of demand in the centre and north of the country.

The combination of these two barriers means that it will be extremely difficult to attain the new target set for 2030, until and unless new break-through technology and/or storage is developed.

Figure 5.164 **Electricity from renewables**



Source: PUA

Energy Efficiency

A new program based on the "Guidance for Energy Efficiency Action Plans under Directive 2012/27/EU", was approved by Israeli government decision #3269 dated 17.12.2017.

This reduces the government's 2030 electricity consumption target to 80 TW/h compared to the "business as usual" scenario, by which electricity generation in Israel would reach 96 TW/h in 2030.

The government program consists of several supportive tools:

- Financial: grants, and subsidies in the form of loans and tax benefits
- Regulation: energy labelling and minimum energy performance standard (MEPS)
- Public awareness

As far as loans are concerned, a specialized fund has been established with $145 million for qualified energy saving projects to be distributed via a tender process. Total energy consumption was divided as per the relevant consumption sectors: residential, commercial and public, industrial and water, transportation, agriculture and the Palestinian Authority, with each sector being examined for its inherent potential for energy savings, suitable policy tools, costs and expected savings.

The building sector is split between residential, commercial & public. The main targets for conservation and efficiency measures in Israel are: air-conditioner systems, lighting (including street lighting), general appliances' efficiency and solar water heaters.

Cogeneration: In 2018 (IEC report), 6 big co-generation power plants with a total capacity of 761 MW were connected to the grid and became operational. An additional 3 co-generation power plants, with a total capacity of 218 MW are in the commissioning stage (as of end 2019). Several small size systems are also operating.

The regulatory framework under which the co-generation projects were established states that the heat and steam generated can be used for either self-use or for onward sale to other end-consumers. The surplus power can be sold to any power consumer via IEC's national grid, whilst the steam can be provided to industrial consumers in the close vicinity of the co-gen station. The prices of both these products are not controlled by regulators, but for commercial reasons have been set by the owners at a discount to the IEC controlled tariff.

Due to a relatively high degree of surplus electricity generation capacity in the market (over 20%), during those hours when the IPPs are unable to sell their surplus output to end-consumers, they are compensated in the form of a commitment by the electricity system manager to buy the energy set at a tariff that has been pre-determined on a project-by-project basis. In times of electricity shortage or emergency, the plants will be dispatched by the electricity system manager.

In 2018, the co-generation regulations were amended so that going forward bilateral sale of electricity will no longer be possible for new co-generation projects and all electricity, other than for self-consumption, must be sold to the "electricity system manager on a half-hourly basis". In addition, the ministry is promoting small size cogeneration projects (3-16 MW). In this respect, a quota of up to 750 MW was published for tendering.

Energy Investment Outlook

Natural Gas

In 2020, the Leviathan gas field came on line with a total investment of $3.75 billion.
In mid. 2022, the Karish gas field will come on line with a total investment of $2.1 billion.

Insofar as natural gas transmission and distribution is concerned, it is expected that the government owned Israel Natural Gas Transmission Company will invest $100 million every year over at least the next 5 years to expand the already 750 km long high pressure transmission system. In the low pressure distribution sector, the 6 private companies with local regional distribution monopolies have an accumulated commitment to invest the same kind of sum (i.e. $100 million per year over the next half a decade).

Oil and Gas Exploration

In terms of gas exploration, there are 18 offshore gas exploration permits which have been granted between 2017 and 2019. In 2019, Energean discovered (April) and successfully appraised (November) the 1.2 TCF Karish North Field, which is expected to come on stream in 2H 2021. Over the next 5 years, the holders of these permits will be conducting a variety of activities ranging from seismic surveys and interpretation with little commitment to drill any new wells during this initial period. Investment in this sector will thus be limited over the next few years.

Electricity

However, Energean has planned to start in 1Q 2022 a drilling campaign, consisting of 3 firm wells and 2 optional, targeting 1 billion of oil equivalent resources (more than 80% in gas). If discovered, this gas could be used also for export purposes.

By 2022, IEC will construct a new 1,200 MW CCGT station at a cost of about $1.2 billion.
IPPs, cogeneration and pumped storage facilities will be investing about $2 billion. In addition to this, as stated in the report, the privatization process of selling 5 power stations over the next 5 years by IEC to the private sector is ongoing. The sale of the first station was finalized at the end of 2019 for 1.9 billion shekels ($550 million).

The second station, which is double the size of the one sold, is at the time of writing this report under the process of being sold. As part of the privatization process, a new government grid management company will also be established, with an estimated start-up capital equity of 1 billion shekels ($288 million). On 1st January 2020, the government gave the green light to invest NIS 250 million ($72.4m.) in wind farm technologies to ensure that the construction of the wind turbine farms will not impact security considerations, and thus circumvent hurdles imposed by the security establishment.

Transportation

There are conflicting figures as to future investment and penetration of electric cars in Israel by 2030. These range from Israel Electric's estimate of 50,000 electric vehicles in use in 2030, the Ministry of Energy's figure of double this number and research firm BDO, predicting that Israel would have 300,000 electric vehicles in 2025 and 1.5 million in 2030. An important turning point will likely take place at the middle of the decade, when electric car prices balance out with the price gasoline-powered vehicles.

Research and Development

In December 2019, the U.S. Department of Energy (DOE) and Israel's Ministry of Energy along with the Israel Innovation Authority have selected seven clean energy projects to receive $6.4 million under the Binational Industrial Research and Development (BIRD) Energy program. The total value of the projects is $15.4 million, which includes $9 million of cost share from the companies selected for funding. The seven approved projects include a project to develop boosting EV charging through energy storage system, a project to optimize energy efficiency, technology for more efficient power supply for grid connected electronic devices, a study to develop a low cost and high efficiency solid biomass and solid waste fuelled electricity generation system.

Nuclear

No nuclear facilities are planned to be constructed.

KOSOVO*

* Throughout this Study, this designation is without prejudice to positions on status, and is in line with UNSCR 1244 and the ICJ Opinion on the Kosovo declaration of independence.

Kosovo*

Economic and Political Background

Kosovo's GDP declined by about 4.14% in 2020, based on preliminary estimates the country's statistical office released on April 2, 2021. In the fourth quarter alone, GDP grew by 0.72% year-on-year. Measured at current prices, Kosovo's GDP totaled €1.9 billion in the October-December period.

The sectors with the highest positive contribution to Kosovo's economic growth in the fourth quarter of 2020 were mining and quarrying, manufacturing, electricity, water supply, information and communication, real estate activities, arts, entertainment and recreation and other services as well as public administration, education and health, professional and administrative activities.

The government implemented the Economic Recovery Programme immediately after the outbreak of the pandemic, allocating €365 million of funds to support businesses, create jobs and stimulate aggregate demand. The Kosovo Assembly approved the additional fiscal stimulus of €200 million (or about 3% of GDP) for the Economic Recovery Programme in early December 2020. Public debt is expected to be 25.9% in 2021 and reach 28% in 2022. Inflation has slowed to 0.8 % in 2020, but is expected to rise to 1.2 % in 2021 and 1.7 % in 2022, according to the latest IMF World Economic Outlook (October 2020). Kosovo has come a long way since declaring its independence in 2008. It is recognised by more than 100 countries as an independent state, has established its first contractual agreement with the EU-the Stabilisation and Association Agreement-has its own international dialing code, and has become a member of several international organisations, amongst much else. Despite these achievements, however, its EU membership remains uncertain. Kosovo is still waiting for visa-liberalisation and the prospect of a final agreement with Serbia has waned.

Energy Policy

The energy strategy of Kosovo 2017-2026 sets out the basic objectives of the Government of Kosovo in energy sector development, taking into account sustainable economic development, environmental protection, sustainable and reliable energy supply to final customers, efficient use of energy, development of new conventional and renewable generation capacities, creation of a competitive market, development of the gas system, and creation of new jobs in the energy sector. This energy strategy, based on a detailed energy sector analysis, has defined five strategic objectives:

1. Security of a sustainable, high-quality, safe, and reliable electricity supply with adequate capacities for stable power system operation;
2. Integration in the Regional Energy Market;
3. Enhancement of existing thermal system capacities and construction of new capacities;

* Throughout this Study, this designation is without prejudice to positions on status, and is in line with UNSCR 1244 and the ICJ Opinion on the Kosovo declaration of independence.

4. Development of natural gas infrastructure;
5. Fulfillment of targets and obligations in energy efficiency, renewable energy sources, and environmental protection

Implementation of this «energy strategy» is of the utmost importance not only for sustainable, high quality, safe, and reliable energy supply in Kosovo, but for the overall economic development of the country, as well as for national security. In view of the various challenges faced in Kosovo's energy sector, it is crucial to have a strong contribution by all stakeholders, including the relevant international institutions, in order to achieve this target.

The key measures to achieve the strategy objectives are:

- Construction of new electricity generation capacities as replacement for the old ones in order to cover growing electricity demand and system reserve requirements, along with integration of the electricity market with that of Albania as a first step towards regional integration;
- Improvement of the operation of the distribution network by increasing efficiency and reducing costs;
- Fulfilment of the conditions for Kosovo's full integration in the common regional energy market and market opening obligations arising from the Energy Community Treaty and SAA;
- Expansion of the existing thermal power systems' capacities and preparation of the necessary conditions for the construction of new thermal systems;
- Preparation of the necessary conditions for natural gas infrastructure development;
- Improvement of overall energy efficiency and fulfilment of energy efficiency obligations arising from Kosovo's participation in the Energy Community Treaty and SAA;
- Greater use of other available energy sources, mainly renewable energy sources, as well as fulfilment of RES obligations from the Energy Community Treaty and SAA;
- Improvement of environmental conditions through the rehabilitation of Thermal Power Plant (TPP) Kosovo B and replacement of TPP Kosovo A with TPP Kosova e RE in line with Directive 2010/75/EC;
- Upon adoption of this Strategy, development of a set of supporting long-term energy sector development studies up to 2050 (as defined in new EU energy policy documents) according to the decarbonisation platform.

Governmental institutions

The Energy Regulatory Office (ERO) is an independent agency established by the Assembly of the Republic of Kosovo in accordance with Articles 119.5 and 142 of the Constitution of the Republic of Kosovo, responsible for economic regulation of energy sector. The duties and functions of ERO are set forth in the Law No. 05/L-084 on the Energy Regulator, among which are the following: creating and operating an efficient, transparent and non-discriminatory energy market; determining criteria and conditions for issuing licenses for the conduct of energy activities; determining criteria and requirements for granting authorizations for the construction of new generating capacities; monitoring and enhancing security of electricity supply; setting reasonable criteria and conditions for energy activities pursuant to tariff methodology.

Ministry of Economic Development (MED) is among others, responsible for energy sector strategy and policy (preparation and implementation), development of secondary legislation, renewable energy sources and rational use of energy, coordination of donors and attraction of investments; Independent Commission for Mines and Minerals (ICMM); is an independent agency pursuant to the Articles 119, paragraph 5, and 142 of the Constitution of the Republic of Kosovo.

ICMM regulates mining activities in Kosovo in accordance with the present law, the sub-normative acts issued pursuant to the Law on Mines and Minerals, and the Mining Strategy. Kosovo Competition Commission (KCC); was established by the Assembly of Kosovo based on the Competition Law no. 2004/36. Kosovo Competition Commission is an independent body and has responsibility for promoting competition among undertakers and protection of costumers in Kosovo.

Transmission System Operator (TSO) and Market Operator (MO)-KOSTT; was established on 1 July 2006, as a result of the restructuring of the energy sector and are responsible for planning, development, maintenance and operation of the electricity transmission system in Kosovo; ensuring an open and non-discriminatory access for third parties; functioning of the new electricity market; providing conditions that encourage competition in Kosovo; and cooperating with neighbouring Transmission System Operators (TSO). KOSTT operates as the Transmission System Operator (TSO) and Market Operator (MO).

Kosovo Energy Corporation J.S.C (KEK) is the electricity utility of Kosovo that covers coal mining and power generation that includes about 97% of electricity produced in the country.

Kosovo Electricity Distribution Company (KEDS): is a private company owned by the Consortium LimakÇalik that performs activities of electricity distribution, maintenance of medium and low voltage network, including metering devices.

Kosovo Electricity Supply Company (KESCO) J.S.C; is a company which was created in 2014, as a result of legal unbundling between distribution operator and supplier.

Kosovo Energy Efficiency Fund (KEEF) is an independent, autonomous and sustainable entity which was established through Law No. 06/L-079 on Energy Efficiency, to achieve the objectives of the Republic of Kosovo in the Energy Efficiency by promoting, supporting and implementing Energy Efficiency measures, as well as attracting and managing financial resources in order to finance and implement investment projects in the area of Energy Efficiency in a sustainable manner.

New Kosovo Electric Corporation (NKEC) J.S.C; is a Publicly Owned Enterprise, fully owned by the Government of Kosovo. NKEC was established as a Joint Stock Company in 2018 for the purpose of taking all electricity generated by the New Kosovo Power Plant (KRPP) based on the requirement deriving from the Agreement between Government of Kosovo and private investor. The KRPP Project Agreements includes the development, design, construction, financing, ownership, operation, and maintenance of KRPP Facility, and rehabilitation of the Site by the GenCo.

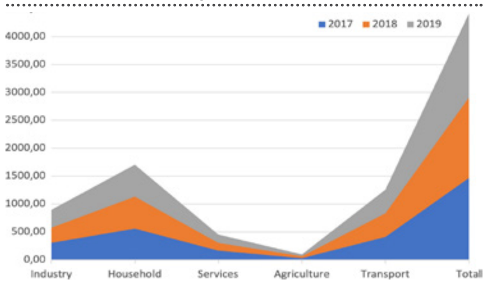
Energy Demand and Supply

Kosovo has the prerequisites for electricity production, not only to cover its own needs, but also to export it. Kosovo's power system is designed to produce lignite-based energy. Nonetheless, in spite of an increase in production in recent years, the domestic production is not sufficient to meet growing consumption and therefore part of Kosovo's electricity consumption is now covered by imports during different time periods especially in peak hours. However, in specific periods, mostly at night – where low tariffs of electricity apply- there is an excess of electricity which is exported.

National energy demand

In 2019, the total final consumption (TFC) reached 1.5 Mtoe, an increase of 15% compared to the 1.3 Mtoe consumed in 2013. The biggest share of consumption pertains to the household and transport sectors, with 575 Mtoe and 422 Mtoe, consumed respectively in 2019.

Figure 5.167 **Share of energy consumption (Ktoe) by economic sector and year**



Source: Kosovo Agency of Statistics – Energy Report 2020

National energy supply

In 2019, Kosovo's Total Primary Energy Supply (TPES) reached 2.7 Mtoe. This is an increase of 74% over the year 2000 when supply was 1.55 Mtoe. The dominant energy source is coal, accounting for 58% (1.55 Mtoe) of the country's TPEs in 2019, increased by 60% compared to 0.97 Mtoe in 2000. The available quantity of coal has increased by 13.84%, compared to 2018. There has also been an increase in the available quantity of oil products by 2.28%, compared to 2018.

Table 5.126 **Overview of primary energy supply in Kosovo (in ktoe)**

	2016	2017	2018	2019
Coal	1684,57	1447,85	1367,49	1556,38
Oil products	660,37	729,63	740,71	753,69
Biomass	368,50	365,16	370,16	361,03
Hydropower	18,36	15,34	28,84	22,26
Solar energy	0,39	0,42	0,44	1,34
Wind energy	0,06	0,05	2,56	7,80
Electrical energy	-43,63	-24,61	14,13	4,60
Total	**2688,62**	**2533,84**	**2524,32**	**2707,11**

Source: Kosovo Agency of Statistics

Energy balance

Based on the long-term energy balance for 2019-2028 approved by ERO, the following are the projections of GDP growth over the next 10 years that are in line with the «Energy Strategy», which were used to forecast the electricity demand.

Table 5.127 **Projections of GDP growth**

Annual growth [%]	2018	2019	2020-2028
GDP Low Growth Scenario	2.2%	2.2%	2.2%
GDP Base Growth Scenario	4.3%	4.3%	4.3%
GDP High Growth Scenario	5.4%	5.4%	5.4%

Source: Statement of Security of Supply for Kosovo

The basic demand scenario for electricity (BDS) foresees a slight increase in demand in the household sector, while it foresees a high increase in the services sector and the industrial sector.

Based on these forecasts, the energy demand (base scenario) in 2019 was forecasted to be 5,814 GWh, whereas in 2028 the demand is expected to reach 6,170 GWh[1].

The respective peak loads for these years are expected to be around 1,177 MW and 1,270 MW[2].

Energy mix

The structure of the primary energy consumed in Kosovo in 2019 consisted of coal, petroleum products (gasoline, diesel, fuel oil, kerosene and LPG), biomass, hydro, wind, solar and biofuels. Electricity is treated as a primary source just for the amount of import and export.

Lignite is the dominant product with a share of 99.97% in total coal, as the primary source available, followed by bituminous coal and other 0.03%. No oil is extracted in Kosovo, including refining raw crude oil, and therefore all oil needs are covered by imports. Imports of oil products in 2019 have been 753.69 ktoe and compared to 2018 there was an increase of about 2.28%. Benzine and Diesel oil account for about 66% of the total amount of oil products available; followed by oil coke, 12%; gasoline with 8%; GLN 4%; etc.[3].

The quantity of consumed firewood in 2019 was 361.03 ktoe. Compared to 2018 there was a decrease of about 2.43%. (Basic data on wood consumption for 2015 are taken from the survey on energy consumption by households).

The amount of hydropower produced in hydropower plants in 2019 was 22.426 ktoe, while the amount of wind-generated electricity was 7.8 ktoe. The amount of solar energy utilized in 2019 corresponded to 1.78 ktoe. According to a government survey, energy consumption in households reached 0.44 ktoe. In 2019 there was no evidence of any biofuel imports. Figure 5.168 shows the energy sources (in percentage terms) as a part of the total energy supply in Kosovo for the year 2019.

1 ERO - Statement of Security of Supply for Kosovo (Electricity, Natural Gas and Oil), 2019

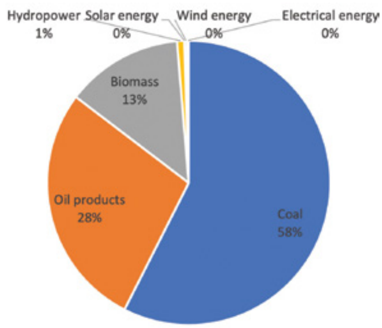
3 Kosovo Agency of Statistics – Annual Energy Balance in the Republic of Kosovo in 2019

Figure 5.168 **Kosovo's energy supply**



Source: ERO Annual Report 2019

The Energy Market

Oil and Petroleum Products

(a) Oil supply and demand

Kosovo has neither domestic reserves of crude oil, nor the capacity for refining it and therefore does not import any crude oil. Kosovo is a net importer of petroleum products, and produces only heavy fuel oil for heating from imported raw materials amounting approximately to 30% of the consumption of heavy fuel oil for heating[4]. There are four licensed production plants, which currently produce heavy fuel oil with less than 1% of sulphur content. Heavy fuel oil with less than 1% sulphur content is produced by mixing heavy fuel oil containing over 1% sulphur with light oils such as gasoline and kerosene.

(b) Oil imports/dependence

Kosovo is a net importer of oil products. Since there are negligible amounts of domestic production and exports, almost all consumption within the country is covered by imports. In recent years the total imports of oil products did not have a significant upward trend, but only slight variations. In Table 5.128 and Figure 5.169 data is presented on consumption, import and export figures (negligible amounts).

[4] ERO – Security of Supply Report 2019

Table 5.128 **Imports – Exports of petroleum products in Kosovo**

Petroleum Products - 2018 [in tons]			
Type	Imports	Exports	Consumption
Benzine	58,881.9	0	58,881.9
Biodizel	0.0	0	0.0
Bitumen	46,408.9	214.3	46,194.6
Dizel	494,247.6	0	494,247.6
Bottled natural gas	687.1	2	685.1
Gazoilet	5,506.4	0	5,506.4
LPG	30,537.1	0	30,537.1

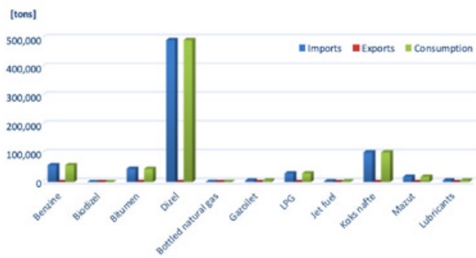
Koks nafte	103,954.9	0	103,954.9
Mazut	18,701.6	0	18,701.6
Lubricants	5,780.1	177.3	5,602.8
Total	767,693.8	393.6	767,300.2

Source: Kosovo Statistics Agency

Figure 5.169 **Petroleum products in Kosovo, 2018**



Source: Kosovo Statistics Agency

Kosovo is almost 100% dependent on imports of oil products with the majority of them originating from neighboring countries. The pattern of imported oil products in 2018 is presented in Table 5.129.

Table 5.129 **Origin of oil product imports in Kosovo, 2019**

ORIGIN OF OIL PRODUCTS IMPORTS [%]		
Country	Petroleum	Diesel
Albania	0.00%	17.90%
Bosnia & Hercegovina	0.00%	0.00%
Montenegro	0.00%	0.00%
Greece	56.28%	45.65%
Serbia	39.60%	20.62%
Macedonia	3.82%	15.70%
Croatia	0.30%	0.13%
Total	100%	100%

Source: ERO – Statement of Security of Supply for Kosovo 2019

Kosovo does not possess any pipelines for crude oil or for oil products transportation. Oil products are imported 75% by road transportation and 25% by railroad.

The law on trade with petroleum and petroleum products[5] obliges all companies dealing with petroleum and petroleum products to maintain storage facilities and sale points and to maintain reserves of at least 5% of their storage capacity at any time for emergency purposes. Currently licensed at storage tanks have approximately 80,000 m3 and approximately 40,000 m3 capacities for retail sale of fuels, while 5% of this capacity equals to 3-4 days of average daily net import. There is additional 50,000 m3 of storage capacity that is not being used and is not licensed for fuel storage. Currently there are 12 storage facilities that are licensed for fuel wholesale (diesel, petrol, LPG)[6].

Kosovo has an open market for oil products including imports and exports, and prices are set freely by the market. With regard to a 10% customs duty, this issue is addressed by the respective legislation in force, which fulfils obligations arising from international agreements (CEFTA, Energy Community Treaty) for the oil sector. More specifically, Law 04/L-163 and Administrative Instruction no.05/2015, amended by Administrative Instruction no.07/2016 for commodities, for which the customs duty isn't charged, specifies that oil products which are exempted from customs duty include: fuel oils, lubricants, bitumen, and calcinated and decalcinated petrol coke.

According to the Law on Trade with relevance to petroleum and petroleum products, the responsible authority for Kosovo's Oil sector is the Department for Regulation of the Oil Sector of Ministry of Trade and Industry. This department has the competences for licensing commercial entities and for undertaking the activities in the oil sector. Price regulation isn't implemented since the market is very competitive with over 40 importers for transport fuels and many other importers of other petroleum products. The wholesale and retail prices are freely set by market forces.

Security of supply[7]

Kosovo's electricity fulfills over 90% of demand from domestic generation, while as far as natural gas is concerned, it should be noted that there is no network developed, whereas all oil and oil products come from imports.

With respect to electricity, the sector is advancing regarding its generation capacities, transmission, distribution and supply of customers in general.
Since Kosovo's energy system is modelled for basic energy production, balancing the system remains one of the key issues. Energy required for the peak period, in addition to local production, is accomplished through imports, and in the case of the generating unit's failure is realized through emergency imports, or sometimes with the application of load shedding as the last measure to keep the system in balance.

Based on the Law on Energy, Article 25 *"the Government may, as an emergency measure, impose restrictions on energy supply for customers…".*

There have been investments in new network equipment as well as maintenance, but also in electricity generation, particularly regarding Renewable Energy Sources.

The transmission network is in good conditions, following the investments in the infrastructure. Kosovo's power transmission network meets the domestic transmission needs as well as the N-1 criterion, except for the Prizren 2 - Rahovec line, which remains in radial supply.
The important issues remain:

- The implementation of the agreement for connection of KOSTT at ENTSO-E;
- Commencement of commercial operation of the line 400kV Kosovo-Albania;
- The allocation of cross-border transmission capacities, which continues to be carried out by EMS and not by KOSTT as a legitimate owner.

[5] Law No. 03/L-138 on Amendment and Supplementation of Law No. 2004/5 on Trade of Petroleum and Petroleum Products in Kosovo
[6] ERO - Statement of Security of Supply for Kosovo (Electricity, Natural Gas and Oil). 2019.
[7] Ibid.

The distribution network still remains in unsatisfactory conditions and investments are required to ensure quality and sustainable supply for consumers.

Reduction of energy to customers due to energy shortages has decreased considerably. The current situation of electricity supply to costumers can be considered acceptable but in order to have better quality of electricity supply to customers, continuous investments are required, especially in the distribution network as well as in production. The issue of balancing the system remains problematic as there is insufficient generation capacity, especially flexible one, which could be activated in cases of power shortages or falls of a larger unit. Thus, in order to cover consumption during peak time, electricity imports are required, whereas for off-peak period, especially at night, there are electricity surpluses which could be exported.

With respect to natural gas, Kosovo does not have domestic natural gas production and is not connected to any natural gas supply operational network. Important issue remains:

- A connection to natural gas supply would be an important option for the introduction of natural gas in Kosovo;
- It is expected that following the finalization of the TAP project, Kosovo will be connected to the natural gas network through the ALKOGAP project, which is in study phase.
- As for oil sector it should be noted that Kosovo does not have sources of unrefined oil or capacities to carry out its processing, therefore Kosovo is a full importer of oil products.
- Currently there are 12 storage facilities which are licensed for wholesale (diesel, gasoline, LPG).
- Wholesale and retail prices are freely set from the market and there is a considerable competition.

Natural Gas

Kosovo has no domestic production of natural gas and it is not linked to any operational natural gas supply networks. A connection to natural gas supply would be an important option for the introduction of natural gas in Kosovo, which would impact diversification of fuel supply and help increase security of supply. Gas supply and consumption in Kosovo is therefore limited to bottled LPG (liquefied petroleum gas).

The official policy of the Kosovo Government is to promote and support the inclusion of Kosovo in the regional natural gas projects. The Trans Adriatic Pipeline (TAP) project could offer great opportunities to Kosovo to connect to the international natural gas network. In this regard, depending on the regional developments of gas projects in Southeastern Europe, the Government of Kosovo remains committed to use all opportunities to get involved in joint natural gas projects as coordinated by the Energy Community.

In order to create the prospect for the development of the natural gas sector and fulfillment of the obligations that Kosovo has as a full member in Energy Community Treaty, the Kosovo Assembly in June 2016, adopted Law no. 05/L-082 on Natural Gas, as part of the package of energy laws.

Following this Law, the transposition of the European third package legislation was carried out, which was relevant for natural gas, mainly:

- Directive No. 2009/73/EC concerning common rules for the internal market in natural gas; and
- Regulation No. 715/2009/EC on conditions for access to the natural gas transmission networks.

The law on natural gas lays out the foundation of the legal and regulatory framework for the transmission, distribution, storage and supply of natural gas and the operation of gas transmission and distribution systems. Consequently, this law determines the organization and functioning of the natural gas sector and access to networks and gas markets. Important interconnection projects between or within Member States – currently in the study phase is the project: ALKOGAP – Albania-Kosovo Gas Pipeline, which is regarded as a favorable option for the connection of Kosovo through Albania with TAP and respectively with the IAP Projects. This project is included in the List of Projects of Energy Community Interest ('PECI' List).

During 2018, the pre-feasibility study for the ALKOGAP project was prepared, and financed through the WBIF platform – EBRD being lead IFI for this project. The main objective of this study was to undertake an initial assessment on the feasibility for the construction of the ALKOGAP pipeline, as an option for supply with natural gas originating from the Caspian region. Connection is envisaged through the proposed regional TAP/IAP gas pipeline network connecting Albania and Kosovo in the first phase and potentially, in the future, to continue to other western Balkans countries. This study has included the following main components:

- A preliminary survey and determination of pipeline trench in Albania and Kosovo;
- Determination of the technical parameters of the pipeline and related stations and equipment, as well as pipeline hydraulic analysis and system configuration and optimization;
- Evaluation of the natural gas demand in Kosovo – namely: estimated consumption of the residential sector, services and industry, district heating including cogeneration of heat and electricity;
- Economic and financial analysis including estimation of the investment costs and O&M, and Cost benefit analysis; - Review and assessment of legal & regulatory and institutional framework, and elaboration of organization of natural gas market in Kosovo;
- Preliminary environmental and social impact assessment.

The pre-feasibility study has further recommended other project implementation phases, emphasizing the preparation of a Gas Master Plan for Kosovo and preparation of a Feasibility Study for this project, which would provide detailed assessment of feasibility and sustainability of the ALKOGAP project, as the main precondition for developing natural gas markets in Kosovo and Albania.

Map 5.47 **Regional gas infrastructure projects and options for the connection of Kosovo**

Source: ERO

The US MCC Programme ("Millennium Challenge Corporation") is carrying out a feasibility study exploring another entry to the gas market through North Macedonia. As part of its Energy Strategy for 2017-2026, Kosovo is also aiming to establish a Gas Transport System Operator and Gas Distribution Operator and invest in natural gas infrastructure[8].

Solid Fuels

Kosovo has large reserves of lignite which ensure long-term electricity generation. However, the problem is the impact on the environment due to emission of greenhouse gas and other polluters. Around 89.23% of Kosovo's installed electricity generation capacities involves power plants that operate with lignite as the primary source of supply[9]. Lignite production in 2018 was 7.17 mton, whereas consumption reached 7.48 mton, with these quantities being smaller compared to 2017. Production and consumption of lignite on a monthly basis, for 2018, is presented in Table 5.130. Concerning imports of solid fuels, it must be clarified that there are not any import of coal or lignite.

Table 5.130 **Production and Consumption of Lignite in 2018**

Lignite Generation/Production	Totali	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Lignite Production (t*1000)	7,170	648	606	727	636	451	549	421	647	558	692	632	605

Electricity

(a) Electricity supply and demand

Kosovo possesses the prerequisites for electricity generation not only to meet local demand but also for export. The electrical power system is mainly designed to generate electricity from conventional lignite sources, therefore maximum load coverage and system balancing remain a major challenge for all stakeholders[10]. Although lignite-generating units that are in operation are very old, over the last few years there has been an increase in electricity production. However, domestic power generation is not sufficient to cover the continuous increase of consumption, hence, part of the electricity consumption in Kosovo is covered by imports over different time periods, especially at peak times. Despite this at certain times, especially during the night (at low tariff period), there are surpluses of electricity that are exported.

The electricity generation capacity in Kosovo is dominated by lignite fired plants Kosovo A and Kosovo B. These two power plants together have an installed total capacity of 1,478 MW. Due to aging and the non-operation of two Kosovo A units, the available capacity of the two TPPs is much lower than the installed capacity. Together, the total available capacity of these units is about 960 MW. Currently, generation of electricity from these power plants covers almost 94% of total generation in Kosovo[11]. In addition, TPP-s, generation is also supported by hydro power plants: HPP Ujmani with an installed capacity of 35 MW, the cascade of Lumbardhi River with a capacity of about 26 MW. In addition there is the AirEnergy – KITKA wind farm with a capacity of about 32.4 MW, as well as some small power plants connected to the distribution system with an overall installed capacity of 25.19 MW.

Table 5.132 shows the installed electricity capacity of Kosovo per plant at operating unit.

Table 5.132 **Installed electricity capacity in Kosovo**

Generator units	Units capacity (MW)			Entry into operation	Life expectancy

Electricity generation in Kosovo has increased over the years. Figure 5.171 shows the overall generation in Kosovo during 2008-2018, where we notice a continuous increase until 2018, with a slight decrease of electricity production in 2014 and 2017.

[10] ERO – Annual Report 2019
[11] ERO – Annual Report 2019

5

The annual generation of electricity in TPPs is planned in line with optimum utilization of generation capacities. Electricity provided at the entry of transmission at TPP Kosova A and TPP Kosova B is planned for **4,495** GWh, where:

- TPP Kosova A = **1,956.7** GWh, at the entry of transmission.
- TPP Kosova B = **2,538.2** GWh, at the entry of transmission.

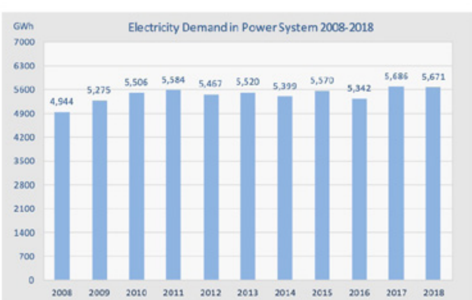
Whereas, the entire national generation, including HPPs connected to the distribution network including wind generators as well as solar panels is planned for an amount of **5,051.1**GWh[12].

Figure 5.171 **Electricity generation in Kosovo (2008-2018)**

Source: ERO Annual Report 2018

The overall electricity demand in Kosovo for 2020, including the supply for consumption in North of Kosovo, is estimated at 6,404 GWh. Fig. 5.172 includes only data until 2018, which shows that there has been an increase of 12% in consumption since 2018.

Figure 5.172 **Electricity Demand in Kosovo's Power System (2008-2018)**



Source: ERO Annual Report 2018

Electricity demand for 2017 was 5,686 GWh, while peak load during winter was 1,161 MW, whereas in 2018 total demand was 5,671 GWh, and peak load during winter reached 1,203 MW.

As stated above, electricity production in most of the years has been lower than the overall demand, but generation has increased at the same time as demand, as presented in Figure 5.173, which shows the balance between electricity generation and demand for 2000-2018.

Figure 5.173 **Balance between total production and gross consumption (200-2018)**

Source: ERO Annual Report 2018

Throughout the years 2000-2018 the overall demand for electricity has increased by an average of about 5.56% per year. During this period the generation units did not cover the electricity demand, which as a result was offset by the import of electricity (except in the years 2013 and 2016 when the generation exceeded the demand, and Kosovo was a net exporter of electricity). The figure above shows the level of net imports, which are used to supply electricity customers. The import towards total demand in the period 2000 - 2018 was 13.8% in the Republic of Kosovo[13] .

(b) Planned new capacity – investments

In recent years, some investments have been made in order to upgrade the electricity system. Such investments provided a safer and qualitative supply to customers. They have increased the security of supply and have resulted in considerable decrease of losses. Kosovo B power plant units will soon reach the end of their forecasted lifespan, so investments and significant rehabilitation measures are planned to be implemented during 2023/2024, in order to adjust these two units to the standards

[12] ERO – Annual Report 2018
[13] ERO - Statement of Security of Supply for Kosovo (Electricity, Natural Gas and Oil), 2019

required for operation, thereby achieving the required level of environmental standards and extending their lifespan beyond 2039.According to the «Energy Strategy», investments in new generation capacity are required in order to safeguard security of energy supply. In this regard, the government of Kosovo has carried out an open and competitive tender, in which case an investor was selected for the construction for a new thermal generating plant, using lignite, with a capacity of 450 MW. In order to facilitate the market integration of the new plant, the Government has established the New Kosovo Electricity Company ('NKEC') to take over the risk of purchasing the generated electricity. The energy purchased by NKEC shall be traded in a transparent, non-discriminatory and market-based market, in accordance with Kosovo's laws and applicable competition rules, including the requirements of the Energy Community. The forecast for electricity generation for the period 2019-2028 is based on electricity generation from the following: TPP Kosovo A, TPP Kosova B, HPP Ujmani, HPPs in Lumbardhi, the KITKA wind power plant, small existing hydropower plants, other renewable energy sources, the power plant Kosova e Re, as well as flexible HPPs. Table 5.133 shows the new generation capacity over the coming years.

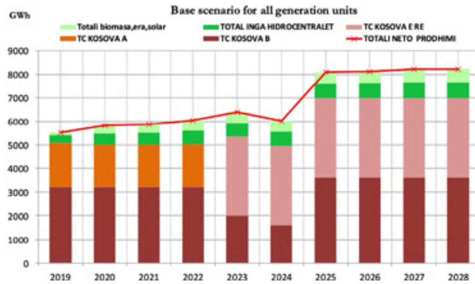
Table 5.133 **New generation capacity in Kosovo**

		Install capacity	In operation	Life
New TPP's	TPP New Kosova			
	G1	P=450 MW	2023	>2050
	TPP Fleksibile			
	G1	P=200 MW	2023	>2050
Renewable Energy Sources	Small HPP			
		P_{2028}=101 MW	2019 - 2028	>2050
	Wind turbines			
		P_{2028}=180 MW	2019 - 2028	2035 - 2045
	Biomass			
		P_{2028}=16 MW	2019 - 2028	>2050
	Solar			
		P_{2028}=85 MW	2019 - 2028	2035 - 2045

Source: The data is taken from the KOSTT document Long-term Balance Sheet 2019 - 2028 approved by ERO

Figure 5.174 presents a forecast of electricity generation in Kosovo until 2028.

Figure 5.174 **Anticipated electricity generation in Kosovo (2019-2028)**



Source: The data is taken from the KOSTT document Long-term Balance Sheet 2019 - 2028 approved by ERO.

(c) Electricity imports - exports

Kosovo's electricity demand is covered by domestic generation and imports realized through cross-border transmission lines. The country's total electricity demand was covered by imports at the level of 14.55%, which represents a decrease of about 7.3 percentage points from the previous year, being about 21.85%. In 2019 2,683,390 MWh entered the country through Kosovo's international electricity interconnections, while 2,322,325 MWh were actually delivered, of which 361,063 MWh for internal consumption, while the rest was in transit. Table 5.134 shows the electricity flows through electricity interconnection lines with neighbouring countries.

The net imports realized in 2018 were 928,492 MWh, with which the energy deficiencies were met, especially at peak times in winter season when demand could not be met only with domestic generation.

Table 5.134 **Electricity flows through Kosovo**

Interconnection flow MWh	400 kV Received	400 kV Delivered	220 kV Received	220 kV Delivered	110 kV Received	110 kV Delivered	Total Received	Total Delivered
Albania			279,079	195,874			279,079	195,874
N. Macedonia	84,457	1,400,701					84,457	1,400,701
Montenegro	600,799	362,143					600,799	362,143
Serbia	1,390,934	59,663	108,958	61,211	16,902	117,563	1,516,795	1238,436
Total	**2,076,191**	**1,822,506**	**388,038**	**257,085**	**16,902**	**117,563**	**2,481,130**	**2,197,154**

Source: ERO Annual Report 2018

5

This amount included electricity imported for both regulated and unregulated customers, the losses in the transmission network and the losses in the distribution network, which is provided through commercial contracts and through the exchange of energy between KEK and KESH. Total electricity imports for 2019 was 13 percent higher than in 2018, which was 825,182 MWh.

Electricity imported through commercial contracts during 2019 was 894,062MWh and corresponded to 50,132,368 € with an average price of 56.07 €/MWh. Although in HUPX the average price of 2019 compared to the average price of 2018 was lower by only 0.64 € / MWh, in Kosovo compared to last year, the average import price was lower by 10.27 € / MWh. Figure 5.175 shows the net electricity import and export of Kosovo.

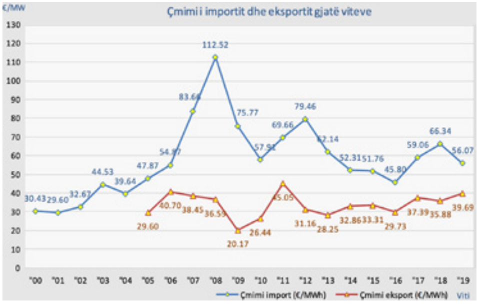
The Energy Regulatory Office mentions that considering the curve line of consumption and non-flexibility of generation units in addition to the lack of electricity, there is often excess in the system, and, in many cases, this occurs on the same day. Therefore, on a single day, and in certain hours, electricity is imported, while in others, there is electricity excess, which must be exported.

Figure 5.175 **Net electricity import and export in Kosovo**

Source: ERO Annual Report 2019

There has been an increase and decrease of electricity prices for imports and exports through the years 2000 – 2019. Figure 5.176 shows the import and export prices between 2000 and 2019.

Figure 5.176 **Import and export electricity prices in Kosovo, 2000-2018**



Source: ERO Annual Report 2019

(d) Tariffs

ERO has jurisdiction for setting tariffs for all energy services. The regulated retail tariffs, applied as from April 2020, for the regulated customers, are shown in Table 5.135.

Table 5.135 **Regulated retail prices in Kosovo, 2020**

Tariffs	Voltage Level of supply	Tariff elements	Unit	Time of day	Approved 2020 1
1	35 kV	Standing (customer) charge	€/customer/month		11.19
		Power engaged	€/kW		5.85
		Active energy (P)	€c/kWh	High tariff	4.92
		Reactive energy (Q)	€c/kWh	Low tariff	3.16
			€c/KVArh		0.67
2	10kV	Standing (customer) charge	€/customer/month		4.62
		Power engaged	€/kW		5.04
		Active energy (P)	€c/kWh	High tariff	5.73
			€c/kWh	Low tariff	3.69
		Reactive energy (Q)	€c/KVArh		0.67
3	0.4 kV Category I	Standing (customer) charge	€/customer/month		2.57
		Power engaged	€/kW		2.97
		Active energy (P)	€c/kWh	High tariff	6.69
			€c/kWh	Low tariff	4.96
		Reactive energy (Q)	€c/KVArh		0.67
4	0.4kV Category II	Standing (customer) charge	€/customer/month		2.97
		Active energy (P)	€/kW	Single tariff	8.83
		Active energy (P)	€c/kWh	High tariff	10.71
			€c/kWh	Low tariff	5.30
5	0.4KV Domestic 2-rate meter	Standing (customer) charge	€/customer/month		1.74
		Active energy (P)	€c/kWh	High tariff	6.75
			€c/kWh	Low tariff	2.89
6	0.4 kV Domestic 1-rate meter	Standing (customer) charge	€/customer/month		1.74
		Active energy (P)	€/kW		5.32
7	0.4 kV (domestic unmetered)	Estimated consumption			
		Standing (customer) charge	€/customer/month		1.74
		Active energy (P)	€/kW		6.75
8	Public lighting	Standing (customer) charge	€/customer/month		3.21
		Active energy (P)	€/kW		9.24

Note: Tariff applies 07:00-22:00 Monday-Saturday during the High Season (1 October – 31 March) and 08:00-23:00 Monday-Saturday during the Low
Season (1 April – 30 September)
Customers are charged reactive energy over allowed, corresponding with cos(Φ)=0.95.
Source: ERO Decision 149/20

(e) Cross-border interconnections

Electricity transmission is of particular importance for security of supply and for the operation of the entire power system of the country. Kosovo's Transmission network represents an important regional node which is interconnected with the European power system.

There are interconnection lines with neighboring countries as follows:

- Albania, North Macedonia, Montenegro, and Serbia - line 400 kV,
- Albania and Serbia - line 220 kV and
- Serbia - two lines 110 kV

Interconnection line 400 kV SS Kosova B - SS Kashar (Tirana) was completed in 2016 and carried out successfully testing, but for political reasons this has not yet become fully operational.

Renewables

(a) Overview of sector's development

Kosovo has a significant potential for expanding the use of renewable energy sources (RES) for electricity generation. The biggest potential sources are wind, hydro and biogas, while solar, geothermal and biomass have lower development potential. The issue of RES is relatively new in Kosovo, taking into account that over 90% of electricity generation is based on thermal power plants. Currently, hydro and biomass, in the form of wood, are the only types of RES used, which contribute significantly to Kosovo's energy supply. The use of solar energy is still at an early stage.

(b) Latest legislation, incentives and national RES policy

Policies in support of RES are based on Energy Law Nr. 05/L-081, which aims to promote the sustainable and economic use of RES and exploit its domestic potential, in order to meet rising energy demand, increase security of supply and ensure environmental protection which is an integral part of the «Energy Strategy» of the Republic of Kosovo.

In order to implement RES policies, the respective Ministry has determined the RES targets for energy, according to the legislation in force, in line with the requirements of the relevant European Union Directive for RES.

The Law concerning the Energy Regulator no. 05/L-084 stipulates that construction of new RES capacity and of new systems for the transmission and distribution of natural gas, including interconnectors, as well as direct electricity lines and direct gas pipelines for the transfer of natural gas will be made in accordance with the authorization procedure under this law, which shall be undertaken by the Energy Regulatory Office, in accordance with objective, transparent and nondiscriminatory criteria.

In order to abide with the legal obligations for meeting the obligatory RES target by 2020, the Ministry of Economic Development has issued Administrative Instructions no. 01/2013 and no. 05/2017 which set the annual and long-term energy targets of energy from RES. These Administrative Instructions have stipulated that the mandatory target for Renewable Energy Sources is 25% of the final gross energy consumption by 2020, as defined in Article 4 of the Decision of the Ministerial Council of the Energy Community Nr. D/2012/04 / MC-EnC.

Kosovo has agreed to a binding RES target of 25 % of its gross final energy consumption by 2020 and a voluntary RES target of 29.47 % . In breaking down the total obligatory target of 25% in gross final energy consumption coming from RES, 14.33% of RES is projected for electricity; 10% of RES for transport and 45.65 % RES for the cooling and heating of buildings. Table 5.136 presents the projected development of RES targets starting from 2009 until 2020, for both mandatory and voluntary targets, for each sector.

Table 5.136 **RES Electricity Capacity in Kosovo (2016-2020)**

Capacity of Electricity from RES					
Primary Energy Source	2016	2017	2018	2019	2020
Photovoltaic	6	7	8	9	30
Wind	1	61	115	129	150
Small HPPs	40	57	181	187	240
Biomass	6	8	10	12	20

Source: ERO Annual Report 2019

Currently the government is in the process of assessing RES integration achievements and setting new targets for the following period. It is expected that Kosovo will further promote RES, in line with potential, obligations and needs, as well as European developments and experience. As an Energy Community contracting party, Kosovo has an obligation to implement European Directives related to the environment and this will remain one of the strategic objectives of the Kosovo energy sector.

In Kosovo, investments in renewable sources are supported through Feed-In Tariffs (FIT). Feed-in Tariffs applicable for electricity generated from Renewable Energy Sources and admitted in the Support Scheme vary for the different technologies as shown in Table 5.137:

Table 5.137 **Applicable Feed-in Tariffs for RES in Kosovo (2019)**

Level of Feed-in Tariffs applicable for RES	
Primary Renewable Energy Source	[€/MWh]
Photovoltaic Energy	136.4
Wind	85.0
New small hydro power plants	67.47
Biomass	71.30

Source: ERO

Feed-in Tariffs are applicable to all applicants, who have been issued electricity production licenses in accordance with Decision on Notification for Preliminary Authorization and Final Authorization, as admitted to ERO's Support Scheme and who have signed the Power Purchase Agreements with MO.

Regarding the promotion of electricity generation from renewable energy sources, Article 14 of Law no. 05/L-081 on Energy requires all participants in the energy sector to perform the following tasks:

(a) When dispatching the generated electricity, the Transmission System Operator, or the Distribution System Operator, shall give priority to electricity generated from renewable energy sources, subject to the restrictions specified for purposes of system security by the Grid Code and other regulation and codes.

(b) The Transmission System Operator and Distribution System Operator shall establish and publish standard rules on who bears the costs of technical determinations, such as grid connections and their grid reinforcements, necessary to integrate new electricity producers supplying electricity produced from renewable energy sources into the interconnected system. Such rules shall be submitted for approval to the Regulator and should be consistent with the Strategy, based on objective, transparent and non-discriminatory criteria.

The Rule on Support Scheme for RES which is being implemented since 2017, defines the regulated mechanisms for supporting electricity generated from renewable energy sources.

Among others this regulation sets:

- The principles of supporting RES Generating Facilities admitted to the Support Scheme;
- The eligibility criteria for admission to the RES Support Scheme;
- The application procedure for admission to the RES Support Scheme;
- The procedure for funding the RES Support Scheme;
- The principles of supporting RES Generating Facilities, in accordance with the Regulated Framework;
- The principles of supporting RES self-consumption generators.

According to the Rule on Support Scheme for RES, all generating units which have been admitted to the Support Scheme have the right to sell their electricity output to the Market Operator through a Power Purchase Agreement for a period of 10 to 12 years, depending on the technology, and with a Feed-in Tariff price. PPA with Market Operator shall be concluded within thirty (30) days following the admission to the Support Scheme.

The achievement of annual RES energy targets was envisaged to be fulfilled in accordance with the penetration of specific RES technologies in electricity generation (RES-E), in heating and cooling production (RES-H) and in the transportation sector (RES-T). To this end, three different sub-targets were introduced so as to facilitate the achievement of the RES energy targets for 2020

These three sub-targets in the 2013 version of the NREAP were as follows:

- 25.64% penetration of RES in the gross final electricity consumption, to be achieved by the installation of small hydropower plants (240 MWe), Zhuri hydropower plant 305 MWe), wind plants (150 MWe), biomass plants (14 MWe) and photovoltaic plants (10 MWe).
- 10% penetration of RES in the final consumption in transport, must be achieved through the deployment of biofuels.
- 45.65% penetration of RES in the final consumption for heating and cooling, to be achieved through the promotion of solar energy (70 MWth), geothermal heat pumps (10 MWth) and biomass in the form of traditional logwood.

Table 5.138 shows the progress of RES penetration compared to the targets set for 2020.

Table 5.138 **Progress towards the fulfilment of RES targets in Kosovo**

	2009	2010	2015	2016	2017	2018	2019	2020

(d) Planned new major projects

RES investment projects are expected to increase in the following years. Based on the Register of Applications for the Construction of New Generating Capacities and Admission to Support Scheme from RES, as published on ERO's website, RES investment projects which are expected to be implemented over the next few years are summarized in Table 5.140:

Table 5.140 **Status of RES projects in Kosovo under different stages of the Licensing Process (Status 2019)**

	Final Authorization		Preliminary Authorization		Pending applications for admission to Support Scheme	
	#	Capacity (MW)	#	Capacity (MW)	#	Capacity (MW)

Energy Efficiency and Cogeneration

(a) National targets

Along with the need and efforts to ensure sufficient energy generation from existing power plants and other alternative sources, energy efficiency in Kosovo is considered by the GoK an essential component of strategic planning and economic development. The Ministry of Economic Development is the lead Ministry with oversight of the energy sector, energy efficiency policy planning and monitoring of implementation.

Table 5.141 shows Kosovo's targets for Energy Efficiency, as defined by Long-term NEEAP 2010-2018, Long-term Energy Balance of the Republic of Kosovo 2015-2024 and NEEAP 2019-2021.

Important political, legal, and institutional steps have already been taken in energy efficiency promotion. Law No.06/L –079 on Energy Efficiency which transposes the Directive 2012/27/EU, was adopted on 07.11.2018. Secondary legislation is under finalization by MED.

Table 5.141 **Kosovo's energy efficiency targets**

TARGETS	2017	2018	2019	2020

5

In order to implement the requirements of Law No. 05/L-101 on Energy Performance of Buildings, which transposes Directive 2010/30/EU, the following regulations were introduced:

- Regulation (MESP) No.02/18 on National Calculation Methodology for Integrated Energy Performance of Buildings adopted on 07.12.2018.
- Regulation MESP No.03/18 of The Procedures on Energy Performance Certification of Building adopted on 10.12.2018.
- Regulation MESP No.04/18 for Minimum Requirements for The Energy Performance of Buildings adopted on 13.12.2018.
- Regulation MESP No. 01/2018 for Inspection of Heating and Air-Conditioning System adopted on 16.02.2018.

(b) Incentive-based initiatives in the building sector

Regarding latest developments, Energy Community mentions that Kosovo has prepared laws on energy efficiency for buildings, which include provisions on certification of buildings, minimum energy performance standards, heating and cooling systems inspections, etc.

In addition to transposing EED, the new Law on Energy Efficiency also laid the ground for the establishment of the first financial mechanism for Energy Efficiency, Kosovo Energy Efficiency Fund (KEEF). KEEF was established in 2019, which made Kosovo the first country in the Western Balkans to launch an Energy Efficiency Fund. KEED will play an important role in financing energy efficiency measures in public institutions such as municipalities and ministries.

Municipal Energy Efficiency Action Plans have been drafted, paving the way for the municipalities to apply for the KEEF in order to implement EE measures and reduce energy consumption

(c) EU funded energy efficiency programmes in the building sector

- In 2019 Kosovo became the first country in the Western Balkans to launch an Energy Efficiency Fund. The Energy Efficiency Fund was launched by the Ministry of Economic Development with the support of the World Bank and the European Union. This fund was created as a result of the adoption of the Law on Energy Efficiency in November 2018. For this fund the Kosovo Government has allocated € 1 million, while World Bank and EU pledged € 10 million .
- During 2018 two renovation contracts were completed by Kosovo Energy Efficiency and Renewable Energy Project (KEEREP) financed by the WB - the contract for package 2 (12 buildings) was finalized by end of March, while package 3 (20 buildings) was finalized by early December of 2018. With the implementation of these two renovation contracts, based on energy audit reports data, substantial energy savings were achieved of approximately 51% on an annual basis, or 13,2390 MWh/a compared to baseline energy, while annual government cost saving in amount of 1.23 mill euro. Around 2.2 MW RES capacity was installed for heating and SHW, whereas the CO_2 savings were of approximately 4700 ton/year.
- MED has implemented energy efficiency measures in 20 schools in 2018 under state budget financing with a total amount of 1.5 mill euro.
- The EBRD Green Economy Financing Facility (GEFF) has been operational in Kosovo since 2018. GEFF provides finance for green economy investments in the residential sector as well as to businesses that provide energy efficiency and renewable energy products and services to households.

(d) Cogeneration: Regulatory framework, installed capacity

Cogeneration in Kosovo is not highly developed. Table 5.142 depicts the current district heating companies with special reference to the Termokos and Gjakova District Heating Systems. Also, the low level of industrial and economic development in Kosovo creates unfavorable conditions for the development of industrial cogeneration.

The Termokos and Gjakova District Heating Systems in Pristina and Gjakova respectively consist of three major activities: heating generation, distribution and supply. Both companies are licensed by the ERO for performing the aforementioned activities. Both state-owned companies are supervised by the Municipalities of Pristina and Gjakova respectively.

Table 5.142 **District Heating Capacity in Kosovo**

Company (City)	Installed Capacity [MW]	Operational Capacity [MW]	Thermal Energy Network	
			Length of the Network (track)	No. of substations
TERMOKOS (Pristina)	2 x 58 = 116	2 x 49.3 = 98.6	Distribution	
	2 x 7 = 14	2 x 6.3 = 12.6	39.0	437
	1 x 4 = 4	3.6	Transmission	(active-425)
	[Kogjenerimi] 2 x 70 = 140	2 x 68.7 = 137.4	10.5	
Sub-total	274.0	252.2	49.5	437
DH GJAKOVA (Gjakova)	1 x 20 = 20	1 x 14.8 = 14.8	Distribtuion	302
	1 x 18.6 = 18.60	1x13.02 = 13.02	13.5	(active-180)
Sub-total	38.6	27.8	13.5	302
Total	312.6	280.0	63.0	739

Source: ERO Annual Report 2018

Throughout the years several investments have been implemented, including the rehabilitation of generation equipment, replacement of the old network of thermal conductors, expansion of the heating network and expansion of heated areas.

Termokos relies on the generation of thermal energy in Co-generation plants in TPP Kosova B; in fact during the 2018/2019 heating season, the entire generation of thermal energy was from cogeneration plants in TPP Kosova B, and so it was not necessary to activate the heavy fuel oil boilers in Termokos Heating. The amount of thermal energy extracted from cogeneration in the 2018/2019 season was 235,079 MWhTH. While the amount of thermal energy received at the heat exchange station in DH Termokos was 229,661 MWhTH, which also represented an increase of 9,90 MWhTH or 4.41% compared to last season (219,954 MWhTH).

Table 5.143 presents the summary data on generation, supply and losses for the entire thermal energy sector.

(e) Planned new major projects

Following ratification of the agreement of 15 January 2015 between the Republic of Kosovo (Recipient) and the International Development Association (IDA), worth of USD 31 million and based on the successful implementation of the Energy Efficiency and Renewable Energy Project for Kosovo (EEREPK), the Ministry of Economy and Environment expressed, through the Kosovo Agency for Energy Efficiency, its readiness to implement the final package worth € 5 million targeting municipalities through the Kosovo Energy Efficiency Fund under this agreement.

Table 5.143 **Energy Performance of Thermal Energy Sector– season 2018/2019**

Thermal Energy Sector – Season 2018/2019				
Description	Unit	DH Termokos	DH Gjakova	Total
Thermal Energy Gross Production	[MWhth]	235,079	9,112	244,191
Loss Quantity in Transmission Network	[MWhth]	5,418	0	5,418
Share of Losses in Transmission Network	%	2.30	0.00	2.30
Own-Consumption	[MWhth]	820	475	1,295
Thermal Energy Net Production	[MWhth]	228,841	8,637	237,478
Loss Quantity in Distribution Network	[MWhth]	19,308	1,728	21,036

Source: ERO Annual report 2019

In order to expand the scope of the program on a more sustainable basis with the establishment of the Kosovo Energy Efficiency Fund, EEREPK's restructuring will secure additional funding, i.e. USD 10.37 million to be channelled through grants to be provided by the EU Instrument for Pre-Accession (IPA II), of which € 9.6 million is in the field of energy efficiency.

All municipalities in Kosovo will benefit from this fund which covers education, health, administration and other sectors. Most importantly, the fund will create a permanent institutional framework, as a financial mechanism, that can contribute to the renovation of public buildings and eventually expand into the residential sector, e.g. apartment blocks, individual houses, and the private business sector.

Energy Investments Outlook

Kosovo fulfills over 90% of its electricity demand from domestic generation, which is largely based on indigenous lignite and does not include natural gas.

There have been investments in new network equipment as well as in maintenance, but also in electricity generation, particularly regarding Renewable Energy Sources.

The transmission network is in good condition, following consistent investments in infrastructure over the years. The transmission capacities fulfil the required criteria, especially following the construction of the 400kV line Kosovo- Albania.
According to the Energy Strategy, in order to cover the local demand for electricity which is growing, and potentially to export electricity, it is foreseen that by 2028 the following generating capacities will be built:
- TPP "Kosova e Re" with an installed capacity of 450 MW;
- Flexible HPP with a capacity of 200 MW;
- Construction of various RES plants
  - 101 MW small HPPs,
  - 180 MW wind turbines,
  - 16 MW biomass, and
  - 85 MW solar energy

With respect to **natural gas**, Kosovo does not have any indigenous natural gas deposits or production and is not connected to any natural gas supply network.

- It is expected that following the finalization of the TAP project, Kosovo will be connected to the natural gas network through the ALKOGAP project, which is in a study phase
- Based on the feasibility study and MCC upcoming projects, exploring the connection to the gas market will be through North Macedonia and Greece.

As for the **oil sector** it should be noted that Kosovo does not have any sources of unrefined oil or capacities to carry out its processing and, therefore Kosovo is a net importer of oil products.
- Currently there are 12 storage facilities which are licensed for wholesale (diesel, gasoline, LPG).
- Wholesale and retail prices are freely set from the market and there is a considerable competition.

RES investment projects are expected to increase in number in the following years. Based on the Register of Applications for the Construction of New Generating Capacities and Admission to Support Scheme from RES there appears to be strong interest.

Through the Kosovo Energy Efficiency Fund, many investments are under way in financing energy efficiency measures in public institutions such as municipalities and ministries in order to implement **energy efficiency** measures and reduce energy consumption. For this fund the Kosovo Government has allocated € 1 million, while World Bank and EU pledged € 10 million. The EBRD Green Economy Financing Facility (GEFF) has also been operational and will continue to provide finance for green economy investments in the residential sector as well as to businesses that provide energy efficiency and renewable energy products and services to households.

MONTENEGRO

Montenegro

Economic and Political Background

Economic profile

As the smallest country of the Balkans, Montenegro has a relatively fragile economy which is transitioning to a market system and is based on financial investments, especially in the energy and tourism sectors (private investment accounts for around one-fifth of GDP). In 2020, the country's economy was severely hit by the COVID-19 pandemic and the global crisis that followed, with the tourism sector (the main driver of growth in recent years) being particularly affected and the simultaneous weakening of both external and domestic demand. Overall, the IMF estimates the GDP to have plummeted by 12% in 2020. Montenegro's economy is expected to rebound thanks to investments supporting construction works and the revival of private consumption, with growth forecasted at 5.5% this year and 4.2% in 2022, though the conjuncture remains volatile and subject to the evolution of the pandemic.

Concerning public finances, Montenegro generally registers a budgetary deficit. In 2020, the country was expected to record a primary surplus; however, the sharp decline in budget revenue (-13.1% y-o-y) and the fiscal measures taken to cushion the effects of the pandemic prompted the government budget deficit to climb to €419.5 million in 2020, equal to 9.8% of GDP, based on data from the Ministry of Finance. The European Commission foresees the deficit to be around 4.7% in 2021 and 3.6% next year. Conversely, over the course of 2020 the debt-to-GDP ratio went from 79.3% to an estimated 90.8%, based on IMF's data.

Another matter of concern is the fact that most of the public debt is denominated in USD and the country has an external trade deficit of almost one-fourth of its GDP. Therefore, Montenegro is vulnerable to a decline in external demand and its high financing needs expose the country to potential changes in risk aversion and disruptions in global financial markets. In 2020, low global energy prices and weak internal demand drove inflation into negative territory, with a modest growth expected for 2021 and 2022 (0.7% and 1.1%, respectively). One of Montenegro's main objectives is to join the European Union: the country acquired the official status of a candidate for membership in December 2010. In order to advance in the accession negotiations, it should demonstrate significant progress in several domains, including the rule of law, the fight against corruption and organised crime.

Although decreasing in recent years, the unemployment rate has been historically high and grew to 20.5% in 2020 (from around 15.3% one year earlier, based on data from the Employment Agency of Montenegro). The rate is expected to decrease over the forecast horizon (16.6% in 2021 and 15.9% in 2022, based on data from the European Commission). The country maintains a large informal sector, whereas the labour force participation rate remains low. Moreover, Montenegro is one of the poorest countries in Europe. The latest data available by the European Commission show that almost 24% of the population is at risk of poverty.

A few months after its inauguration, Prime Minister Zdravko Krivokapic's government is far surviving its shaky start. The August 2020 elections ended the Democratic Party of Socialists' ('DPS') three-decade rule, bringing into power a new diverse coalition of parties with a slim parliamentary majority. These include the Serb nationalist alliance For the Future of Montenegro ('ZBCG'), the liberal United Reform Action ('URA') and the centrist Peace is Our Nation ('MNN').

The Krivokapic government, which is comprised mostly of technocrats belonging to or with close ties with the Serbian Orthodox Church, was formed with the express purpose of dismantling the hegemony of DPS, which had designed and captured most of the country's institutional apparatus. This was always likely to be a tall order, given its one-seat majority in parliament and DPS leader Milo Djukanovic's continued occupancy of the presidency – which, although limited in power, is an office that is nonetheless highly influential.

Energy Policy

National Energy Policy

The "Energy Policy of Montenegro until 2030" is the main strategic document which establishes three main priorities for the development of the energy sector of Montenegro: security of energy supply, development of a competitive energy market and sustainable energy development. According to the Government Working Plan for 2019 it is envisaged to prepare a new Energy Policy for 2040.

The Energy Policy recognizes three main priorities and twenty key strategic objectives that need to be addressed by 2030. These are shown in Table 5.144:

Table 5.144 **Main priorities of the Montenegrin Energy Policy by 2030**

	Priority	Meaning
1	Security in energy supply	Permanent, secure, high quality and diversified energy supply in order to meet buyers demand
2	Development of a competitive energy market	Development of a competitive energy market Securing liberalized, non-discriminatory, competitive and open energy market on the basis of transparent conditions. Establishing of competition in market activities (electricity and natural gas production and supply), provide the basis for a price policy for all different forms on solely market principles, as well as creating conditions for new energy undertakings likely emerge (independent energy producers, suppliers, traders);
3	Sustainable energy development	Securing the sustainable development of the energy sector based on accelerated, but rational use of indigenous energy resources in compliance with the principles of environment protection, increased energy efficiency (EE) and increased use of renewable energy sources (RES), as well as the need for the socio-economic development of Montenegro.

Source: Energy Policy until 2030

The **"Energy Development Strategy of Montenegro 2030"** was adopted in 2014. The Energy Development Strategy specifies long-term development objectives and guidelines for the development of energy supply and meeting of energy demand, while taking into account technological and economic criteria and environmental protection criteria; the development direction of energy infrastructure, taking into account possibilities for encouraging the use of renewable energy sources and increasing energy efficiency and long-term energy balance forecasts, timeline and methods to be used for tracking progress and monitoring the achievement of objectives, as well as the assessment of their effects on the economy; tentative financial resources for the implementation of the strategy.

The **National Renewable Energy Action Plan (NREAP)** by 2020 was approved by the Government on 18th December 2014. NREAP defines dynamic utilization of natural resources, as well as the planned use of technologies required to meet the national target for the share of energy produced from renewable sources in the gross final energy consumption.

Fourth Energy Efficiency Action Plan (NEEAP) for the period 2019-2021 was approved by the Government on 27th June 2019. NEEAP is fully in line with the key strategic documents in the field of energy and sustainable development while it also defines the national target for energy efficiency.

Government Institutions

The role of the Montenegrin Government in the energy field is to define and implement: (a) the National Energy Policy and the Energy Development Strategy, (b) long-term and annual energy balances and policy for their implementation, and (c) provide for the implementation of environment protection measures.

The key stakeholders in energy sector of Montenegro are:

- The Ministry of Economy (MoE), through the Directorate for Energy, Directorate for Energy Efficiency and Directorate for Mining and Geological Explorations, is responsible for developing and implementing energy policy. According to the Law on Energy and the Law on Efficient Use of Energy, the Ministry is also responsible for the preparation of strategic documents in the energy field, as well as for the development of the legal framework. The Ministry of Economy is also responsible for energy system and policy modelling. However, due to the lack of capacity and resources in the ministry, this process is usually supported by the donor community.

The review and update of strategic documents related to energy is mainly coordinated by relevant directorates within the ministry.

- The Energy Regulatory Agency (REGAGEN) is the energy regulator of the country. REGAGEN was established in 2004 as an autonomous, functionally independent, non-profit organisation that carries out its public authorisations in the energy sector in accordance with the Law on Energy. Regulation is carried out in a non-discriminatory and transparent manner in accordance with EU directives. In addition, the Law on Energy specifies duties and responsibilities of REGAGEN in terms of its regulatory oversight of energy entities.
- The Ministry of Sustainable Development and Tourism (MoSDT) is the governmental authority which is responsible for several areas that interact with development of the energy sector, particularly: spatial planning, construction, environmental protection and climate change. Inter-ministerial cooperation regarding activities such as adoption of spatial plans, construction of energy infrastructure or development of building codes is very important for the coherent development of the energy sector. The MoSDT is also responsible for the legal framework in the area of environmental protection as well as for the implementation of the UNFCCC, the Paris agreement.
- The Nature and Environmental Protection Agency is the governmental authority responsible for issuing environmental permits, i.e. Strategic Environmental Assessment (SEA) and Environmental Impact Assessment (EIA) forms.
- The Chamber of Economy of Montenegro is a business association representing the general interests of the economy and all economic entities in Montenegro. The Chamber of Economy also actively presents business opportunities and encouraging investment in the Montenegrin economy, relevant to the development of the energy sector of the country.
- The Administration for Inspection Affairs is an authority responsible for inspection affairs in different areas which are relevant for the implementation of the legal framework in the energy field, as well as investment in energy infrastructure.

Energy Demand and Supply

The key facts concerning energy production and consumption in Montenegro for the years 2018, 2019 and 2020 (est.) are shown in Table 5.145.

Table 5.145 **Energy production and consumption for 2018-2019 and estimates for 2020 (in ktoe)**

	2018			2019			2020		
	Realised			Realised			Anticipate

Total	551	859	64	526	840	62	529	910	58

Source: Energy Balance for 2020
*the coal that has been used in TPP Pljevlja is not shown here but the equivalent is taken into account in electricity generation

The electricity sector of the country is highly dependent on the country's hydrological situation and the water level in the rivers, as evidenced by the fluctuation of the share of hydropower in the total primary energy supply over the years, e.g. sharp decreases of 56% and 31% in years 2011 and 2014, correspondingly.

The existing industry is characterized by a high level of energy intensity, requiring large amounts of electricity, which has a predominant share in the energy balance. In the past few years progress in energy management in aluminium and steel production has been achieved so that energy consumption is reaching expected level. In 2018 total energy consumption amounted 859 ktoe, out of which 35% was covered by electricity, 39% by petroleum products, 23% covered from biomass and 3% was covered by lignite (excluding the coal used by thermal power plant in Pljevlja).

In 2018 the domestic electricity production covered total electricity consumption and some amounts of net exports have been realized (274GWh).

The electricity production is realized from hydro power plants amounting 2137 GWh or 57%, 1444 GWh or 39% is realized from thermal power plant while the rest amounting to 163GWh or 4% from wind farms.

In 2019 the situation was slightly different mostly because of the hydrological conditions. The generation from hydro power plants was lower amounting 1688 GWh. On the other hand, because of the expansion of wind farm projects, the generation from wind amounted to 299GWh. While thermal power plants generated 1520 GWh. The difference between generation and consumption was almost the same and hence only a small amount of net electricity was imported (26GWh).

Ministry of Economy of Montenegro in its Energy balance for 2020 has planned for a total electricity of 3454GWh, out of which 1823GWh from HPP, 312GWh from wind farms, 2GWh from solar plants and 1317GWh from thermal power plant.

Montenegro imports 100% of its oil needs (oil corresponds to 39% of the total energy consumption). The country has large enough hydroelectric potential, but only 17% of it is actually exploited.

In view of increased energy consumption, the imports of oil derivatives have been growing over the last decade. On the other hand, the transportation sector is 100% dependent on imported oil apart of the railway system which uses electricity. It is significant to note that biomass is being used in high amounts while small amounts have been exported and almost 100% of it corresponds to domestic production. The most significant trend of the last decade has been the increase in the overall energy consumption.

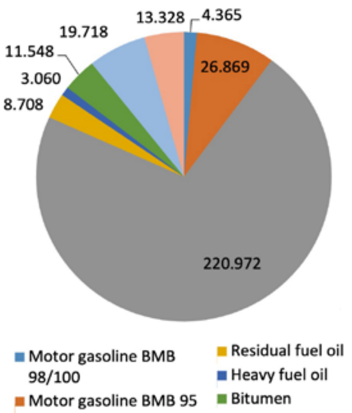
In Montenegro there are no oil refineries and there is no natural gas network and pipelines to provide natural gas.

The Energy Market

Oil and Petroleum Products

Current balance overview of oil products is given in the next Figure 5.179:

Figure 5.179 **Oil and petroleum products balance in tons for 2019**



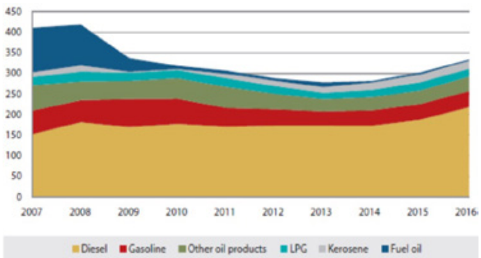
Source: Ministry of Economy of Montenegro 2019

Montenegro does not have its own oil production or refining industry, and all oil products are imported. The main characteristic of the oil retail market in Montenegro is the leading role of Jugopetrol AD (owned by Hellenic Petroleum) which has a dominant position compared to other market players dealing with marketing and sale of oil products. Total consumption of oil products in 2019 amounted 308568 tons, out of which diesel corresponded to 220972 tons, which was the most widely used oil product in Montenegro with a share of 72% in total consumption.

The Ministry of Economy of Montenegro anticipated an increase of oil product consumption by 17% in 2020. As significant increase is anticipated for diesel which is mainly used in the transport sector, as well as more than doubling of the consumption of bitumen as it is used for the construction of the Bar-Boljare highway.

Overall, the consumption of oil products decreased by 19% over the last decade. Figure 5.180 shows that the trend of reduced consumption is mainly due to a sharp decrease in the consumption of fuel oil (mazut). The latter is associated with the decline in industrial production of aluminium oxide. The consumption of diesel and kerosene has increased by 43% and 69%, respectively, and is related to the growing energy demand of vehicle and airplane fleets. As of 2016, 96% of diesel was used by transport, and the remaining 4% was used as a heating fuel.

Figure 5.180 **Consumption of oil products 2007-2016**



Source: Ministry of Economy of Montenegro 2019

The transport sector dominates the consumption of oil products. The sector's share has been increasing over time, reflecting not only the increasing demand of the transport sector, but also the decline in industrial production since 2009.

Upstream sector - Oil and Gas Exploration

Most of the available data refers to offshore hydrocarbon exploration. So far, around 10.000 km2 of 2D seismic profiles, 4 drillings and around 310 km2 of 3D seismic researches have been carried out in the offshore areas. Exploration which has been carried out so far indicates the existence of hydrocarbon reserves; however more reliable estimations of hydrocarbon deposits may be provided only after the completion of the verification phase of identified reserves.

This paragraph needs to be totally revamped. ENI-Novatek have recently completed their exploration drilling, offshore Montenegro, but they have not announced any results yet. Energean is expected to announce its plans regarding a potential exploration drilling in 1Q 2021.

The findings of the first drillings will show whether there are commercially exploitable reserves of oil and gas. The results of the exploratory drillings will show further if there are sufficient oil and gas reserves in the chosen structures.

In accordance with the Agreement on Concession for Research and Production of Hydrocarbon in blocks 4, 5. 9 and 10, signed with the Italian-Russian Consortium Eni-Novatek in 2016, 3D geophysical imaging of the blocks was carried out in November and December 2018.

The seismic research for oil and gas in offshore areas began on November 2018. Surveys are planned for approximately 1,200 square kilometers of sea area, for which the concession was awarded to the Italian-Russian consortium Eni-Novatek. With the help of sound-air cannons, as well as special geomicrophones, which are several kilometers long and connected to ships, an assessment will be made of whether there are grounds for commercial exploitation of the oil and gas deposits in the Montenegrin waters. Some analyses show that Montenegro has 51 billion cubic meters (bcm) of gas and 144 million cubic meters (mcm) of current resources, which correspond to about 438 million barrels of oil. The data referred to the 330 sq. kilometers in Ulcinj.

The state will reap all profits from oil exploitation through the application of a surface charge, a refund for oil and gas produced, and a tax of 54 per cent. In the final analysis, the estimate is that, depending on the scope of exploitation, the state would receive between 62% and 68% of the total revenues from these activities.

Downstream and midstream sectors infrastructure

The storage of petroleum products and LPG in Montenegro (2018) was undertaken by 32 entities, of which 22 performed both activities. The storage of petroleum only products was undertaken by seven entities, while only three entities involved in LPG storage. Total storage capacities corresponding to petroleum products the end of 2018 amounted to 142,327 m³, of which gazoline product storage capacities corresponded to 138,959 m³, while LPG storage capacities amounted to 3,368 m³. In 2018, the storage capacity was increased by 656 m³ (632m3 gazoline products and 24m3 petroleum gas).

Of a total storage capacity of 142,327 m³, some 126,292 m³ belong to Jugopetrol AD Podgorica, of which its Bar Installation is 110,170 m³, petrol stations between them have 6.895 m³, aviation services in Podgorica and Tivat share to 9,040 m³, while three yachting services, in Budva, Herceg Novi and Kotor, share 187 m³. A part of the 16,035 m³ storage capacity belongs to other energy entities, which undertake the storage of petroleum products and LPG in gas stations and yachting services. The energy entity with the highest storage capacity for LPG is Montenegro is Bonus DOO Cetinje, with a total capacity of 1,100 m².

Security of Supply

Montenegro depends entirely on imports of oil derivatives although there are good prospects for crude production from local oil fields and from the exploitation of the country's hydrocarbon resources. Consumption of oil derivatives in 2018 amounted to 332 ktoe, which mainly consisted of diesel fuel, gasoline and jet fuel/TNG. Consumption of fuel oil has dropped due to reduced use by the Aluminum Factory of Podgorica because new technology has been introduced in the plant. The Aluminum Factory is mainly using gas to cover its own needs so that the use of residual fuel oil has been eliminated, and instead LPG is being used in the various industrial processes.

Consumption of oil derivatives in 2019 amounted to 312 ktoe, while 367 ktoe are anticipated for 2020. Oil derivate consumption amounted around 38% of total energy consumption in the country. Since petroleum products are fully imported, they are a very important factor in terms of security of energy supply.

In addition, Montenegro has limited brown coal and lignite reserves. The required amounts are exploited from coal mines in Berane and Pljevlja.

Planned projects

The Government of Montenegro is implementing a number of preparatory steps for potential gasification which could be achieved through infrastructure development related to the Ionian-Adriatic Pipeline (IAP) and/or the Trans Adriatic Pipeline (TAP). The construction of a natural gas pipeline network will enable both a stable natural gas supply to Montenegro and its transit to other countries in Western Balkans. The Government of Montenegro has already implemented the following activities to support the IAP and TAP projects. In 2016, the IAP Project Management Unit (PMU) was established, consisting of one representative from the national energy authority and one representative from the natural gas transmission system operator (TSO), from all four signatories to the Memorandum of Understanding and Cooperation on the implementation of the IAP project - Albania, Bosnia and Herzegovina, Montenegro and Croatia.

Map 5.48 **Ionian - Adriatic Pipeline in Montenegro**

Source: Ministry of Economy of Montenegro 2019

In 2017, the Government adopted a Master Plan for the development of the gas transport system (gasification) of Montenegro, accompanied by a report on strategic environmental impact assessment as well as guidelines for the planning of priority investments in gas pipeline projects. The Master Plan explains the construction of the TAP (with total capacity of 5 billion cubic meters of gas per year and with a total length of 530 km), which is an important project for EU gas infrastructure, as well as the gasification of several large cities inside the country.

Natural Gas

Natural Gas supply and demand and relevant infrastructure

Since the last SEE Energy Outlook (2017) nothing much has been done in order to bring gas to the country. Still there is no access from international networks although there are several possible ways to supply the country with gas. The most likely option is the Ionian Adriatic Pipeline (IAP) project crossing Montenegro.

Montenegro still has not developed any gas infrastructure nor has a gas market been established. It is assumed that, thanks to the planned project of the Ionian Adriatic Pipeline (IAP), it will become possible to introduce natural gas in the near future. Estimations of final consumption of natural gas are based on the assumption that the IAP regional pipeline would pass along the coast of Montenegro and that gasification would include only coastal towns. Other than raising the energy standard of gasified households, this would represent a strong incentive to further develop industry, especially tourism, along the coastal area. By 2030, final gas consumption could reach 46 million of m3. Households are likely to participate with a large share in consumption, followed by industry. Services, mainly tourism, could see consumption from 9 to 12 million of m3 of natural gas.

National NG Policy - Strategic Plan

The Energy Development Strategy of Montenegro by 2030 stipulates the following recommendations about further development of the gas sector:

- Continue the recent exploitation activities in potential oil and gas reserves in the Adriatic Sea,

- Continue with the feasibility study for the Ionian Adriatic Pipeline and determine the optimal route through the territory of Montenegro taking in consideration long-term economic growth of the country,
- Continue with intensive cooperation with other participants in key projects (IAP and TAP) in the region.

The most important project by far is the Ionian-Adriatic Pipeline (IAP), which would connect Montenegro with Croatia and Albania and allow for gas imports into the country. Natural gas is a sector which is planned to play an important role in the energy market of Montenegro in the coming years. The development prospects of natural gas appear promising for future investment. Given the fact, that tourism is the upcoming and dominant sector of Montenegrin economic development, the introduction of a system providing natural gas will definitely have a positive impact on the extension of the tourist season.

Solid Fuels

Supply and Consumption

After hydropower, coal is the second most important source of electricity production in Montenegro. Coal is mined in the north of the Montenegro in the Pljevlja region. This region is home to three coal basins: Pljevlja basin (under exploitation); Ljuce-Sumanski basin (almost depleted); and Maoce Basin (new coal mine). According to Montenegro's energy development strategy the total balance reserve of the Pljevlja region amounts to around 188.4 million tons. All coal produced in Montenegro is used in the local market, where about 97%-98% is consumed by the TPP Pljevlja, and the rest is consumed by households, industry and services. Thus, the production of the coal is mainly dependant on the electricity production cycle of the Pljevlja TPP, which, in turn, is influenced by the availability of hydropower and energy demand. It should also be noted that the power plant underwent modernisation in 2009, which negatively impacted coal production in that year. The Pljevlja TPP, which has been in operation for more than 35 years, will soon be upgraded in order to comply with the requirements of EU environmental standards. In March 2018, the Elektrorprivreda Crne Gore (EPCG), the company owning the TPP, selected a consultant to design the reconstruction of the plant.

Local production and exploration

The total production of lignite from the Pljevlja coal mine in 2018 was 1.539.122 tons, while in 2019 it reached 1.579.048 tons whith the Ministry of Economy of Montenegro announcing plans for 1.602.000 tons for 2020. In addition, brown coal is being exploited from the coal mine in Berane. The total production of brown coal from this mine was 56.448 tons in 2018, 33.635 tons in 2019 while according to Ministry of Economy of Montenegro plans of 58.300 tons production in 2020 is expected. Possible reserves in Pljevlja amount to 198.9 million tons while those of the Berane basin are estimated at around 158 million tons. However, due to inadequate research, total presumed exploitable reserves in Berane fields have been estimated at only 18,5 million tons. The company Rudnik Uqlja AD Pljevlja exploits coal in Pljevlja area with 100% of its shares being owned by the National Power Utility (EPCG) which is government owned.

Planned new projects

There are no plans for the construction of new TPP in future after the government decided not to build the TPP Pljevlja II plant due to environmental, economic and social reasons

Montenegro's power utility Elektroprivreda Crne Gore (EPCG) has launched a tendering process for the environmental reconstruction of the Pljevlja thermal power plant (TPP) Pljevlja Block 1. The upgrading will increase the TPP's installed capacity from 225 MW to 300 MW. Environmental upgrading will result in a reduction of all emissions and coal combustion products, as well as of chemical processes accompanying electricity generation so as to limit them, all in line with the statutory regulations of Montenegro and the EU directives on emissions from coal-fired TPPs.

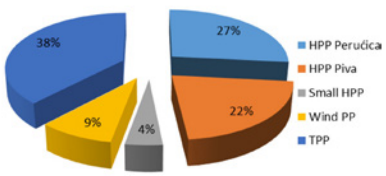
Electricity

Electricity Supply and Demand

The electricity market in Montenegro is small, with a total installed capacity of 1025 MW provided by HPPs, the Pljevlja TPP and the Krnovo and Mozura wind farms.

The electricity sector of the country is highly dependent on the country's hydrological situation and the water level in the rivers, as evidenced by the fluctuation of the share of hydropower in the total primary energy supply over the years, e.g. sharp decreases of 56% and 31% in years 2011 and 2014, respectively. A favorable hydrological situation in 2010 and 2013 allowed HPPs to operate at maximum capacity during these years. The availability of hydropower has clearly influenced the variability of the net import-export balance over time, but this is not on its own the most important factor. The production capacities have been constantly increasing since 2014 mostly due to the development of small hydro and the construction of the first wind farm that became operational in 2017.

Figure 5.181 **Power plant share in generation 2020**



Source: Energy Balance for 2020, Ministry of Economy

The Ministry of Economy of Montenegro anticipated total electricity generation of 3454 GWh in 2020. 27% of the electricity is planned to be generated from HPP Perucica, 22% from HPP Piva, 4% from Small HPPs, 9% from Wind PP and 38% from thermal power plant Pljevlja. Anticipated electricity production in 2020 is likely to be around 1% lower than the realized generation in 2019.

Installed Capacity

Electricity generated in Montenegro is mainly produced from the following plants:

- Coal Thermal Power Plant (TPP) Pljevlja with an installed capacity of 218.5 MW;
- Hydropower Plant (HPP) Perucica with an installed capacity of 307 MW;
- HPP Piva with an installed capacity of 342 MW;
- 19 small HPPs with total installed capacity of 33 MW;
- Krnovo wind farm with installed capacity of 72 MW
- Mozura wind farm of 46 MW.

Thermal Plants

There is only one thermal power plant in Montenegro in the region of Pljevlja where most of the coal mines are located. It began operation in 1982 and the total amount of coal used in 2019 was 1442668 tons (calorific value 9.211 kJ/kg) while the plan for 2020 is 1% higher. The installed capacity is 218.5 MW with the annual generation output in 2019 of 1520 GWh, while the plan for 2020 is 1317 GWh.

Hydroelectric plants

There are two big hydropower plants in Montenegro and seven small ones that are owned by EPCG. The hydroelectric power plants are: "Perućica" with installed capacity 307 MW and the Hydro Power plant "Piva" with installed capacity 360 MW. The Perućica plant in 2019 produced 841 GWh which corresponds to 24% of electricity demand. The HPP Piva has three generator sets, each with capacity of 120 MW and it produced in 2019, 778 GWh which corresponds to 22% of electricity demand. In 2020 the generation from HPP Perucica is planned to 920 GWh while in HPP Piva 750 GWh.

Apart of 7 small HPPs owned by EPCG, significant number of small hydro power plants have been constructed by private owners. A total of 90 MW of new generating capacity of small HPPs should be put into operation by 2021. The new small HPPs can play a significant role in the energy system, as they can potentially increase the existing electricity production by about 10%. From 2015-2017, the Government of Montenegro conducted three tenders and granted 18 concessions for the construction of 37 small HPPs. From 2014-2018, the construction of 13 small HPPs was completed.

Wind farms

There are two wind farms: Krnovo wind farm with installed capacity of 72 MW and Mozura wind farm with installed 46 MW.

Nuclear plants

Montenegro does not have any nuclear plants and does not have any plans for the future.

RES applications

Incentives for the purpose of obligatory share of energy from renewable sources in total final consumption are defined by the Law on Energy and consist of: privileged status during purchase of electricity produced, incentive prices at which that energy is purchased, period of validity of privileged status for purchase of electricity, exemption from balancing service payment system and priority in the transmission of generated electricity to the system. Electricity producers, after obtaining the status of eligible producer, are entitled to incentive measures.

Feed-In Tariffs (FIT) were established by the Law on Energy and further regulated by the Decree on Tariff System for Determining Incentive Prices for Electricity Produced from RES and High Efficiency Cogeneration. The FITs are based on the type of RES and the scale of the installation According to the law, FITs are provided for 12 years. In 2019 the Government of Montenegro cancelled FIT for new producers and electricity price from new energy generation facilities will be formed on market based models without privileged status and guarantied purchases.

Planned New Capacity - Investments

All the facilities for the electricity production (plants) and transmission (grids) are too old and the need of modernization is crucial for the electricity sector of Montenegro. Apart from renovation, Montenegro must invest in the construction of new electricity production plants to meet the growing needs which accompany high economic development rates. Based on a letter of interest by the German company WPD, a tender for the lease of state property for a construction of wind farms in the municipality of Budva and Bar was completed and the winner was WPD. The tender predicts construction of WPP 75 MW of installed capacity. It is important to note that the tender involves the implementation of the project according to the market principles, respectively, a decision that there are no financial incentives in terms of the guaranteed purchase price. The only thing that can be offered is purchase at market prices.

Taking into account the new spatial planning preconditions and the interest of investors, the tender will be realized during 2020 for lease of the state property for the construction of solar power plant at the site Velje Brdo, Municipality of Podgorica. The tender will provide for the construction of a power plant of at least 50 MW of installed capacity. The tender will be implemented according to market principles.

Construction of the WPP Gvozd implies the continuation or the second phase of construction of the WPP Krnovo, which is already part of our production system. The project is currently under development by the national energy company (EPCG) and Austrian Ivicom (one of the companies that have developed the project WPP Krnovo). Company Ivicom has contracted the development of the Study of utilisation of wind power potential with an expected production of electrical energy and the Feasibility study of the project. Development of these studies is ongoing. Preliminary data show that the value of the project is about 70 million euros, and installed capacity of power plant 50 MW. Depending on the results of the final studies, EPCG business decision on the next steps of the project will be defined. This means that then will be chosen the optimal scenario of the finance arrangements for the project, selection of contractors, or potential selection of partners for the eventual establishment of a project company for the realisation of this project.

Currently, activities are under way and involve forming of a final base for realisation of the project of construction of the HPP Komarnica. Contract on development of Conceptual design with Feasibility study and an Environmental impact assessment, worth 1.3 million euros, was signed in 2018. Adoption of the Detailed Spatial Plan on the proposed solution is expected in 2019, which will create preconditions for announcement of tender for the creation of the main project and execution, by the end of this year.

According to the preliminary data of the analysis of the project worth, it will amount to 260-290 million euros, and the installed capacity of the plant will be 155 MW with annual production of about 210 GWh.

The realization for the construction of solar power plants with an installed capacity of up to 1 MW is possible through the issuance of an energy permit. Based on 14 energy licensing decisions issued by the Ministry of Economy, it is planned to build power plants on roof structures with a total installed capacity of about 7.4 MW and planned annual production of about 9.4 GWh. At the time of preparation of the report, the solar power plant on the roof of the investor-owned hall in Bandići, Danilovgrad Municipality, with an installed capacity of 416 kW and planned annual production of 556 MWh, has acquired the status of privilaged producers.

According to the Conclusion of the Government of Montenegro, the Ministry of Economy on 19 May 2018 published a Public Invitation for Lease of State-Owned Land at the Site of Briska Gora - Ulcinj Municipality for the Construction of a Solar Power Plant. Following the invitation, bids from three bidders were received, and it was determined that the first-ranked bidder was the Fortum and EPCG Consortium (consisting of Fortum Corporation, Finland, Elektroprivreda Crne Gore AD Niksic and Sterling & Wilson, India), which committed itself to land leased a 250 MW solar power plant. In accordance with the above, the Government of Montenegro has made the Decision on long-term lease of the land in question for a period of 30 years, after which the Land Lease Agreement for the construction of a straw plant with the aforementioned consortium was signed.

Cross-border interconnections

The transmission system operator Crnogorski elektroprenosni sistem (CGES) belongs to the State (55% of the shares), the Italian TERNA (some 22% of the shares) as well as several investment funds. The electricity market operator COTEE is fully owned by the State.

CGES has a transmission network consisting of the transmission lines long over 1300 km (the total length of the transmission lines in the territory of our country, which is the fixed assets of CGES, is 1305.86 km). The transmission network consists of 45 transmission lines:

- Six 400 kV transmission lines (Lastva - Podgorica 2, Lastva - Trebinje, Podgorica 2 - Ribarevine, Ribarevine - Peć, Ribarevine - Pljevlja 2 and Podgorica 2 - Tirana);
- Eight 220 kV transmission lines (HPP Perućica - Trebinje, Podgorica 1 - Perućica, Podgorica 1 - Koplik, Podgorica 1 - Mojkovac, Mojkovac - Pljevlja 2, Piva - Pljevlja 264, Piva - Pljevlja 265, Piva - Buk Bijela;
- Thirty-nine 110 kV transmission lines, of which three are double circuit lines (2x110 kV) and four are operating at 35kV;
- Two 110 kV cables (Podgorica 3-Podgorica 5 and 2 Nikšić-Kličevo)

CGES performs the activity of electricity transmission in Montenegro through the transmission network at 400 kV, 220 kV and 110 kV voltage levels, as well as system control and maintenance and development of the transmission network.

CGES has a transmission network consisting of the transmission lines long over 1300 km (the total length of the transmission lines in the territory of Montenegro, which is the ownership and fixed assets of CGES, is 1305.86 km) and 24 substations at 400kV, 220kV and 110kV voltage levels. The total transformation capacity of the transmission network of Montenegro is 3846.5 MVA (with a total of 53 transformer units).

Montenegro and Italy have officially put into operation their submarine power link on 17 November 2019, built by Italy's Terna in a joint project with Montenegrin transmission system operator CGES. The link is seen as the first "electrical bridge" between the Balkans and the rest of Europe.

The interconnection will allow a bi-directional exchange of electricity between the two countries of 600 MW of power initially, which will become 1,200 MW when a second cable is laid within the next few years.

The 1.15 billion euro ($1.27 billion) project consists of an interconnection between Montenegro - Italy (underwater cable) and enhancement of the internal 400 kV network in Montenegro. The total length of the power line is 445 km and 423 km of it is laid on the seabed. SEE CAO is in charge for organization of capacity auctions on undersea power interconnector between Italy and Montenegro. First yearly auctions for 2020 on ITME border were conducted on 11th December, monthly auctions for January were held on 20th December while Daily allocation started on 27th December for delivery day 28th December. This whole process was followed by great interest of energy traders and resulted in greatest number of participants so far.

Tariffs

The price of electricity for households with two-tariff meters in Montenegro amounted to € 10.30 c/kWh, including all taxes and VAT, while the average price of electricity in EU countries was € 21.10 c/kWh. In 2018, the average realized electricity price, including the fee for the promotion of renewable energy sources for customers connected to the distribution system, amounted to € 8.65c kWh (not including VAT), which was 0.28 € c/kWh or 3.31% more than in 2017. This increase was due to an increase in prices in the wholesale electricity market, in relation to which EPCG, as a supplier, adjusted the prices at which it supplies distribution customers.

Electricity prices in 2018 compared to 2017 are for customers connected to:
- 35kV higher by 0.04 € c/kWh or 0.67%;
- 10 kV higher by 0,36 € c/kWh or 4,84%;
- 0.4 kV overall higher by 0.29 € c/kWh or 3.31%;
- 0.4 kV - households two-tariff measurement higher by 0.26 € c/kWh or 3.11%;
- 0.4 kV - households single tariff higher by 0.37 € c/kWh or 3.93%.

On 13 December 2019, EPCG approved prices for end users electricity supply for the period 01 January - 31 December 2020, for all customers' categories. Table 5.146 shows prices and tariff models for households including fee for RES within Green Model.

Table 5.146 **Electricity tariffs models for households**

Basic Model	VT	5,2424	€c/kWh
	NT	2,6212	€c/kWh
Blue Model	VT150	4,8434	€c/kWh
	NT150	2,4217	€c/kWh
	VT+	5,5340	€c/kWh
	NT+	2,7670	€c/kWh
Red Model	VT+NT	4,4932	€c/kWh
Green Model	VT	5,2424	€c/kWh
	NT	2,6212	€c/kWh
	Naknada	0,2000	€c/kWh

Source: Electric power company of Montenegro - EPCG (https://www.epcg.com/domacinstva/tarifni-modeli)

The price of electricity is not the same during the day. Different prices apply in the bills as lower (NT) and higher (VT) tariffs.

Planned HPP and Small HPP

In the past, significant activities were carried out within the framework of small hydropower projects over a large number of water areas. Based on the six tendering procedures implemented, 18 concession contracts are being implemented, which envisages the construction of 37 small hydropower plants. Also, on the basis of the energy license, 18 concession contracts were concluded, which envisaged the construction of 18 small hydropower plants whose installed capacity is below 1 MW individually. In accordance with the above, on the basis of 36 concluded concession contracts, a total of 55 small hydropower plants have been planned, of which 13 have been completed so far and have received a operating permit. The total installed capacity of all small hydropower plants whose construction is foreseen by the concluded contracts is about

96 MW, and the total annual production is about 313 GWh. The value of investments for all anticipated small hydropower plants is estimated at around € 160 million.
Also see 5.3.

Renewables

Overview of sector's development

Taking into account the importance of renewable energy sources from an environmental and technological point of view, in strategic planning of energy development, Montenegro has decided to develop the production of energy from renewable sources and to achieve the national target set by Decision 2012/04/MC-EnC of 18 October 2012, adopted at the 10th meeting of the Ministerial Council of the Energy Community. The decision establishes an obligation for Montenegro to achieve the national target, which provides that in Montenegro the share of energy from renewable sources in total gross final consumption will reach the level of 33%, as well as the obligation for Montenegro to implement Directive 2009/28/EC on promotion. the use of energy from renewable sources in its legislative system.

In order to fulfill the established obligations, the Government of Montenegro adopted a Program for the Development and Use of Renewable Energy Sources, which sets out the national targets for the use of renewable energy sources, incentive measures, deadlines and the timetable for its implementation.

Pursuant to the Law on Energy and the Strategy of Energy Development of Montenegro until 2030, the Government of Montenegro has adopted the National Action Plan for the Use of Energy from Renewable Sources until 2020, which defines the way of using energy from renewable sources, as well as the planned use of technologies needed. to meet the national target for the share of energy produced from renewable sources in total final energy consumption.

The technologies used for the production of electricity from renewable sources in smaller production plants are still not economically competitive with conventional power plants, so in Montenegro a system of guaranteed purchase of produced electricity at incentive prices from preferential producers of electricity from renewable sources and high-efficiency cogeneration is used. In addition, privileged producers are also exempt from the balancing costs they incur.

Installed capacity per source

Electricity generated in Montenegro is mainly produced from the following plants:
- Hydropower Plant (HPP) Perucica with an installed capacity of 307 MW;
- HPP Piva with an installed capacity of 342 MW;
- 19 small HPPs with total installed capacity of 33 MW;
- Coal Thermal Power Plant (TPP) Pljevlja with an installed capacity of 218.5 MW;
- Krnovo wind farm with installed capacity of 72 MW
- Mozura wind farm of 46 MW.

As far as geothermal is concerned, no significant geothermal potential has been identified in Montenegro.

Planned new major projects

See subchapter "Planned new capacity – Investments" in Electricity.

Energy Efficiency and Cogeneration

National targets

According to the Energy Community Treaty membership, the obligation of Montenegro is to achieve the indicative energy savings target which represent savings in the amount of 9% of average final consumption of energy in the country over a five-year period. According to the Directive, the established period of time for meeting the indicative energy savings target is from 2010 until 2018.

Concerning the realization of the indicative energy saving target for the period 2010-2018, a preliminary analysis (using the "bottom-up" method - BU) was made, on the basis of the available data, which shows that the energy savings achieved in the previous nine-year period amounted to 49.76 ktoe, which represents 84.5% of the overall indicative target. The calculation of the energy savings with "top-down" method (TD) was not possible due to the unavailability of data from the energy balances for 2018.

The process of preparation of official energy balance for 2018 is to be finalized, after which energy savings will be calculated by using the TD method in the separate analysis, which will be completed by the end of January 2020. Within the same analysis, a more comprehensive analysis of savings will be made by using BU methods.

The government of Montenegro adopted the fourth Energy Efficiency Action Plan for the period 2019-2021 (4th APEE) in July 2019. For the period 2019-2021 EEAP determined an indicative target at annual level in the amount of 4.16 ktoe of final energy consumption (i.e. 6.54 ktoe expressed in primary energy equivalent).

Incentives based initiatives in the building sector

In order to further develop the basic legal framework in the field of energy efficiency on the final consumption side, as well as to harmonize national legislation in line with EU directives, the Ministry of Economy during 2018 prepared 14 additional bylaws to implement the Law on Efficient Use of Energy. Their enactment is foreseen in 2019-2020, including the following:

Furthermore, the Ministry of economy has implemented a number of energy efficiency projects in order to improve EE in buildings, jointly with international and local partners:

- MEEP - Montenegrin Energy Efficiency Project
- EEPPB - Energy Efficiency Program in Public Buildings.
- MONTESOL - Interest-free credit line for installation of solar-thermal systems for households
- ENERGY WOOD - Interest-free credit line for installation of heating systems on modern biomass fuels (pellets, briquettes) for households
- SOLARNI KATUNI - Project related to installation of photovoltaic solar systems in summer pasture lands.

The Ministry of Economy has also launched an Energy Efficient Home program aimed at reducing heating costs and increasing household comfort, achieving a significant reduction in CO_2 emissions in the household sector, and developing a market for biomass heating systems in Montenegro.

In order to reduce pollution in the Municipality of Pljevlja, co-financing of pellet procurement is carried out for citizens who already have pellet heating.

EU funded energy efficiency programmes in the building sector

Implemented activities and achieved results:

1. ENERGY WOOD - interest free loans for the installation of heating systems using modern biomass. The Ministry of Economy has implemented the Energy Wood program, with the aim of establishing an attractive and sustainable financial mechanism for providing interest-free loans to households for installing heating systems (boilers and stoves) on modern biomass (pellets, briquettes). Under the Energy Wood program, citizens were able to apply for loans up to € 3,500, with a repayment period of up to 5 years, and an interest rate of 0%, for installing a heating system, ie. stoves and boilers on modern forms of biomass. In the previous period, 3 phases of the Energy Wood program were implemented, out of which the last 2 in the implementation period of the 3rd EEAP. Details of the program implementation are given in the table below:

Table 5.147 **Program implementation**

Phase (duration)	Funds	No. of installed heating systems
I (2013-2015)	130.000 € - donation from the Luxembourg Development Agency	243
II (2015-2018)	240.000 € - donation from the Government of the Kingdom of Norway	532
III (2017-2018)	85.000 € - state budget	235

Source: Fourth Energy Efficiency Action Plan for the period 2019-2021, Ministry of Economy

2. SOLARNI KATUNI - Installation of photovoltaic solar systems in summer pasture lands

The Ministry of Economy in cooperation with the Ministry of Agriculture and Rural Development is implementing project "Solarni Katuni", aimed at installing photovoltaic solar systems in households residing on summer pasture lands which are not connected to electricity grid. Within the project, 243 photovoltaic systems were installed in summer pasture land, so far out of which 54 in implementation period of 3rd EEAP.

ENERGY EFFICIENT HOME - interest-free loans for installing heating systems on modern biomass and performing works to improve the energy performance of the building envelope.
In 2018, the Ministry of Economy provided € 120,000 in for the implementation of the program Energy Efficient Home, which began in October 2018. This program is a continuation of the program ENERGY WOOD, which has been expanded by other EE measures.

The goal of the Energy Efficient Home program is to offer households in Montenegro, through interest-free loans (up to 8,000 €, with a repayment period of up to 6 years), the opportunity to achieve economic and energy savings by using biomass heating systems and financing works to improve energy performance of the building envelope (installation of thermal insulation on façade walls of residential building and installation of energy efficient joinery).

Within the first phase of this project, € 33,339 was spent for the implementation of EE measures in 93 households in Montenegro.

3. In the past, several units at local government level have continued the realization of subsidy programs for the installation of solar systems in new buildings, by reducing utility fee (fee for utility land) in the amount of 50-200 € per square meter of installed solar panel, depending on the local self-government units. Also it is important to mention the activities of certain local self-government units, e.g. Municipality of Tivat on establishment supporting programs for citizens (interest free loans), in cooperation with commercial banks, with the aim of implementing energy efficiency measures in the households on the municipality territory.

Future activities:

1. Continuation of the program of Energy Efficient Home over the next period. For the purpose of realization of this project in 2019 budget funds were provided in the amount of € 100,000, which are foreseen for the implementation and interest rate subsidy at commercial banks. Plan for the implementation of the program after 2019, has to take into account the following:

- In case GEFF Residential project is started (see below), it is necessary to modify the program Energy Efficient Home in a way that there is no overlap regarding the implementation of EE measures;
- The implementation of support programs aimed at improving energy efficiency in households and other sectors of final energy consumption should be gradually transferred to the Eco-Fund (see measure H.3).

2. Launch of the GEFF-Residential project in Montenegro. Within the EU support, Western Balkan countries have received the funds to support the household sector for the implementation of energy efficiency measures through the Western Balkans Residential Green Economy Financing Facility (GEFF-Residential) project, which is coordinated by EBRD.

In order to implement project in Montenegro, it is necessary that EBRD establish cooperation with commercial banks in Montenegro (one or more), which would be obliged to establish dedicated credit lines for energy efficiency. In the event that citizens realize energy efficiency measures by using funds from these credit lines, they acquire the right to subsidies, from the allocated EU funds, in the amount of 15-30% of the amount of the investment;

Continuation of promotion of the subsidy program for the use of renewable energy sources in other Montenegrin local self-government units according to the possibilities.

Cogeneration: Regulatory framework

Article 14 of Energy Efficiency Directive (EED) stipulates that member countries shall prepare an overall analysis of potential of high-efficiency cogeneration, as well as efficient systems of district heating and conditioning.
Certain activities were initiated in Montenegro in the past with the aim of meeting obligations stemming from Article 14 of EED, which primarily relate to the transposition of basic requirements of this article into the current Energy Law.

In addition, drafts bylaws of the Energy Law which will define in details the application of high efficient cogeneration, district heating and cooling were prepared under the project "Optimal use of energy and natural resources" financed from IPA 2012. The plan is to adopt these documents during 2019.

In terms of strategic framework, it is important to mention that the Energy Development Strategy of Montenegro for 2016-2020 (adopted by the Government in January 2016) has elaborated the issue of high efficient cogeneration and district heating and cooling under specific programs:

- The programme of district heating / cooling by locations - biomass, gas, heat pumps, municipal waste, high efficient cogeneration plants (program No. 10.3.4)
- The programme for developing Study of introducing district heating system in local communities in the municipalities in the north part of Montenegro (Kolašin, Berane, Žabljak and Plužine) as well as in other cities of Montenegro (Nikšić, Bijelo Polje, Cetinje, Podgorica) for the use of biomass or waste heat from industrial processes and implement Projects if studies show their justification (program No. 10.3.5)
- Heating system project for the town Pljevlja (program No. 10.3.6)

The Energy Law, in Article 20, has stipulated the adoption of a special Action Plan for the development and use of district heating and/or cooling and high-efficiency cogeneration, adopted by the Government for a ten-year period.

With the aim of planning the development of district heating and/or cooling sector and also the high-efficiency cogeneration section, in the action plan, the Law obliges the Ministry of Economy to analyze the profitability, taking into account the technical feasibility of different solutions and technologies.

In accordance with legal obligations, in 2016 and 2017 the Ministry of Economy has prepared a study for the evaluation of the potential for the implementation of high-efficient cogeneration, under the project "Development of sustainable use of energy" . Based on this study the Ministry has prepared a Draft Action Plan for the development and use of district heating and/or cooling and high-efficiency cogeneration. The Action plan was finalised and adopted in 2019.

Planned new major projects

Improving efficiency by revitalizing HPP Piva Phase II

The objective of the project is to increase the generation of electricity from the available hydro potential in order to increase the security of the HPP, increase the share of RES in electricity generation and further the improvement of energy efficiency of current hydropower facilities.

Improving efficiency by revitalizing HPP Perucica Phase II

The objective of this project is to increase the production of electricity from the available hydro potential to increase the safety of the HPP plant, increasing the share of RES in the production of electricity and further improving the energy efficiency of existing hydropower facilities.

Improving efficiency by installing energy efficient block transformers T1-T5 - HPP Perucica

The installation of modern transformers with reduced losses directly influences the reduction of transformational losses in the respective power plant and enables more efficient evacuation of electricity to the grid compared to the existing solution, which results in increased production at the power plant threshold.

Improving efficiency through the renovation of small hydropower plants (Rijeka Crnojevica, Podgor, Savnik, Musovica River and Lijeva rijeka).

Target contributions are, as follows:

- Increase the electricity production from available hydro potential
- Improving energy efficiency in existing SHPPs
- Increasing the safety of the SHPP plant,
- Increasing the share of RES in electricity generation and
- Reduction of losses in the distribution network.

Development of the transmission and distribution network and improvement of its operation

This measure has effects primarily in transmission and distribution sector. **Development of decentralized energy production by energy prosumers (producers-consumers)** The overall target is to increase electricity generation from RES and aim for further energy efficiency improvement of power systems through decentralized generation.

NORTH MACEDONIA

North Macedonia

Economic and Political Background

The pandemic has had a negative impact on overall economic activity in North Macedonia, where average GDP fell by -5.4% in 2020. According to the State Statistical office, North Macedonia's economic output shrank by an estimated 4.5% year-on-year in 2020. Exports of goods and services fell by 10.9% in nominal terms in the year under review, while imports declined by 10.5%. Household final consumption decreased by an estimated 5.6% last year. The unemployment rate declined throughout 2020, reaching 16.1% in the fourth quarter, which is 0.5% lower than last year. IMF estimates that North Macedonia's GDP will expand by 5.5% in 2021, significantly higher than -5.4% in 2020.

Several major corruption scandals involving high ranking government officials were revealed in the timespan of only several days in March 2021. In the midst of a serious undersupply of vaccines, the government was implicated in severe misconduct in the procurement of vaccines from the Chinese company Sinopharma. Only several days later, the former Secretary General of the government was implicated in corrupt purchases and conflicts of interest dating back to his time in office. Meanwhile, the government was also accused of failing to apply for support funds, resulting in the country receiving zero support from a €530 million EU fund, aimed at supporting the management of the coronavirus.

Energy Policy

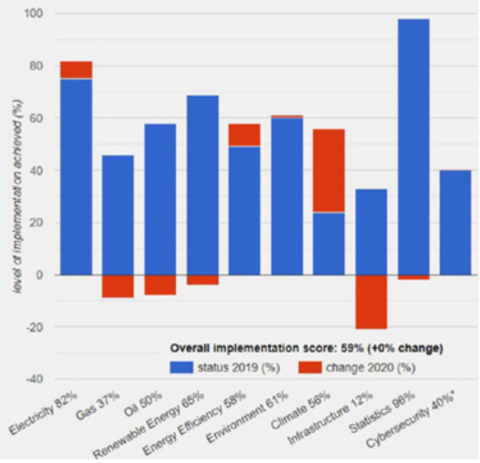
National Energy Policy

North Macedonia, as a candidate country for membership in the EU, faces certain challenges related to the implementation of structural reforms, of which the energy sector is of special significance for the country's overall development. The country has actively participated in regional initiatives, considering that it was the first country in the region to sign a Stabilization and Association Agreement with the EU in 2001. In 2005 it was granted candidate status for EU membership.

With respect to its international commitments referring to the energy sector, North Macedonia signed and ratified the Energy Charter Treaty and the Protocol on Energy Efficiency and Related Environmental Aspects, the Energy Community Treaty (EnCT), the United Nations Framework Convention on Climate Change and the Kyoto Protocol. EnCT represents North

Macedonia's main agreement in force with EU acquis requirements, and extends the acquis to the territory of the country. According to the EnCT, North Macedonia harmonizes its national legislation with the existing legislation of the EU (Acquis Communautaire) on energy, competition, renewable energy sources (RES), energy efficiency (EE), oil reserves, energy statistics, infrastructure, environment and climate. The overall implementation performance for 2019/2020 is presented in Figure 5.185. In addition, it actively participates in all related regional initiatives led by the EU and EnC Secretariat, among which the Western Balkan 6 Initiative (WB6) on establishing a Regional Electricity Market and Sustainability Charter, as well as the EU4Energy Governance and the Energy infrastructure and donor initiatives[1].

Figure 5.185 **Level of implementation of EnCT legislation in 2019/2020 (status: 1 November 2020)**



*2020 first assessment year

Source: Calculated and compiled by the Energy Community Secretariat [2]

The strategic commitments in the energy sector, currently limited to the requirements of the Third package for electricity and gas markets (TPEGM), have been incorporated in the Energy Law adopted in 2018[3]. The Law sets a legal framework for the domestic energy sector, including electricity, gas, renewable sources, oil and security of supply, as well as respective secondary legislation. The new Energy Efficiency Law[4], transposing the EU Energy Efficiency Directive, Energy Performance of Buildings Directive, Regulation on Labelling of energy related products, and Directive on Eco-design of energy related products, was adopted in February 2020. In addition, in the fields of electricity and natural gas, adoption of the acquis from the EU Network Codes (NCs) including the NC on wholesale energy market integrity and transparency is progressing in accordance to the schedule established by the EnCT. The Government has adopted several strategic documents over the past years that define the country's national energy policy. Among those are the Strategy for Energy Development until 2040[5], the Strategy on use of renewable sources until 2020[6], the Strategy for Improvement of the Energy Efficiency until 2020[7], the Action Plan on use of renewable sources until 2025 with a vision until 2030[8], the Third National Energy Efficiency Action Plan until 2020 (3rd NEEAP)[9], the Programme for the promotion of renewable sources and energy efficiency in households for 2018[10] and the same Programme for 2019[11]. In October 2020, North Macedonia became the first ever EnC Contracting Party submitting its draft integrated National Energy and Climate Plan (NECP) to the EnC Secretariat.

Governmental institutions

The Government / Ministry of Economy

The Ministry of Economy (MoE)[12] is in charge of the country's energy sector on behalf of the Government. The main energy related tasks in the Ministry are strategic planning, development of relevant legislation and implementation of energy policy. This includes the policies for liberalization of internal energy markets, EE and RES, as well as the use of new technologies. MoE is responsible for the preparation of the respective primary but also of the secondary legislation, collecting relevant data about the energy production, supply, demand and preparation of the Annual Energy Balance. MoE oversees the development of the energy sector, particularly the increase of EE and incentives for the wider use of RES, competitiveness, secure energy supply and environmental protection.

To achieve these objectives, MoE has developed cooperation with the National Academy of Sciences and Arts, especially the Research Centre for Energy, Informatics and Materials, as well as with the University Ss. Cyril and Methodius and other state and private universities. Within the EE field, MoE cooperates with the Ministry of Environment and Physical Planning, the Ministry of Finance, the Ministry of Transport and Communications and the Energy Agency.

The Energy Agency

The Energy Agency of North Macedonia has been formed for the purpose of providing support to the Government in the implementation of the energy policy. A growing number of NGOs are also involved in energy issues and related environmental problems.

The Energy Regulatory Commission

The state regulatory authority which has competences over the whole energy sector is the Energy and Water Services Regulatory Commission (ERC)[13]. ERC became operational in 2003 and it was empowered to regulate the sector and monitor the energy markets. According to the Energy Law, the Board of ERC consists of five commissioners appointed by the Parliament. The ERC budget, as well as its Annual Report, is also subject to parliamentary approval. Within the framework of authorities given by the Energy Law, the ERC is independent in its operation and decision-making process.

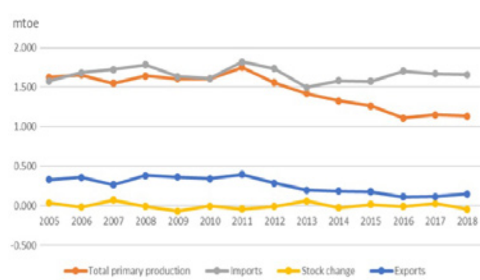
The current competences of ERC are in compliance with the TPEGM.ERC is a member of the Energy Community Regulatory Board (ECRB), Energy Regulators Regional Association (ERRA) and European Water Regulators (WAREG), and observer in the Council of European Energy Regulators (CEER). In July 2019, ERC applied for participation in the working groups of the Energy Regulatory Cooperation Agency (ACER).

Energy Demand and Supply

National energy demand and supply, energy dependency and energy mix

The national primary energy demand and supply between 2005 and 2018 are presented in Figure 5.186. The graph specifically shows data on production, net import and net export of primary energy, as well as reserves, the sums of which coincide with the total consumption of primary energy (gross inland consumption).

Figure 5.186 **Production of primary energy, net imports, net exports and variations of reserves in North Macedonia, during 2005 - 2018**



Source: Information collected from the official page of the State Statistical Office

12 Ministry of Economy of North Macedonia, http://www.economy.gov.mk/Home?lang=2
13 Energy Regulatory Commission of the North Macedonia, http://www.erc.org.mk/DefaultEn.asp

The import of primary energy shows a slight increase since 2005, attaining a share of 63.8% in the gross inland consumption in 2018[14]. However, its importance is highlighted by the decreasing total primary production in recent years. This situation places North Macedonia within the group of countries that are highly dependent on imports. The State Statistical Office calculates the energy dependency as a key energy indicator. Its development over the past few years is given in Table 5.148.

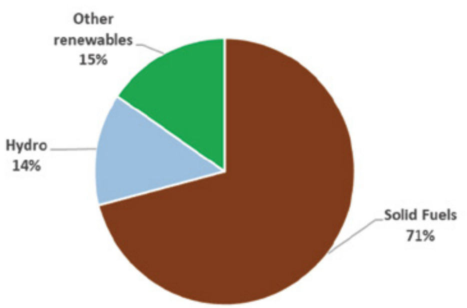
Table 5.148 **Energy dependency in North Macedonia, 2015 - 2018**

2018	58.06 %	preliminary data
2017	56.76 %	definitive data
2016	59.00 %	definitive data
2015	52.09 %	definitive data

Source: Information collected from the official page of the State Statistical Office

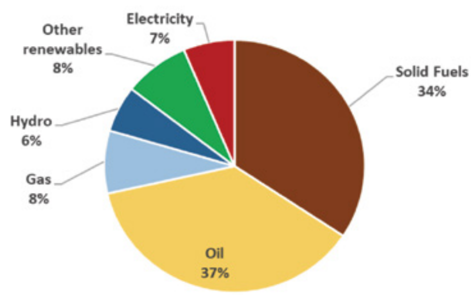
Figures 5.187 and 5.188 illustrate the primary energy mix in North Macedonia, using the State Statistical preliminary data for 2018. Figure 5.189 shows the production of energy by types (primary fuel mix) in mtoe and Figure 5.190 the shares of individual types of fuels in the gross inland consumption. In 2018, the total production of primary energy in North Macedonia was 1.13 mtoe or 43.6 % of the total 2.60 mtoe gross inland consumption.

Figure 5.187 **Energy production by type of fuel of North Macedonia, 2018**



Source: Information collected from the official page of the State Statistical Office

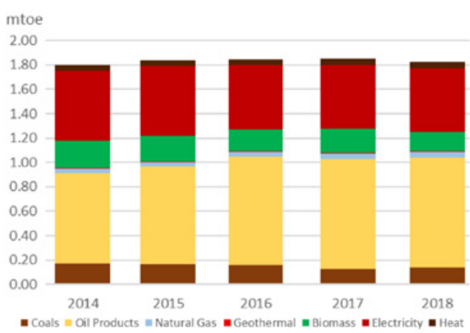
Figure 5.188 **Gross inland consumption by type of fuels in North Macedonia in 2018**



Source: Information collected from the official page of the State Statistical Office

The largest final energy consumers in 2018 were: Transport with 38.2 %, Households with 25.4 % and Industry with 21.6 % (of the available for final consumption). The ratio between final energy consumption and gross inland consumption, which varied from 60 % up to 71.3 % over the last decade, was 71.3 % in 2018. In the final energy consumption of 1.85 mtoe, in 2018, as it is presented in Figure 5.91 and Figure 5.192 the biggest share belongs to petroleum products (49%) and electricity (29%).

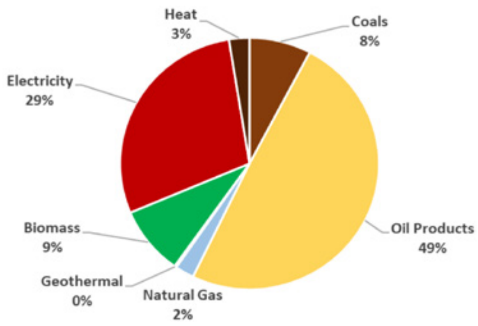
Figure 5.189 **Consumption of final energy by type of fuels in North Macedonia, during 2014 - 2018**



Source: Information collected from the official page of the State Statistical Office

[14] State Statistical Office of North Macedonia, Energy, http://www.stat.gov.mk/PrikaziSoopstenie_en.aspx?rbrtxt=64

Figure 5.190 **Share of individual type of fuels in the consumption of final energy in North Macedonia**

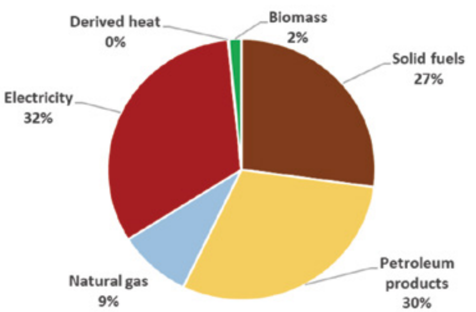


Source: Information collected from the official page of the State Statistical Office

A brief analysis of the data presented draws our attention to the unfavourably small contribution of natural gas in the final energy consumption against the high consumption of electricity. The main contributor to this fact is the consumption of the metal melting industry of the country.

The contributions of the individual fuels in the final energy consumption of industry and households in 2018 is given in Figure 5.191 and Figure 5.192, respectively[15]. One further unfavourable observation in this respect (because of the low efficiency factors involved) is that households largely use electricity for heating purposes.

Figure 5.191 **Final energy consumption in industry by type of fuel, 2018**



Source: Information collected from the official page of the State Statistical Office

Figure 5.192 **Final energy consumption in households by type of fuel, 2018**

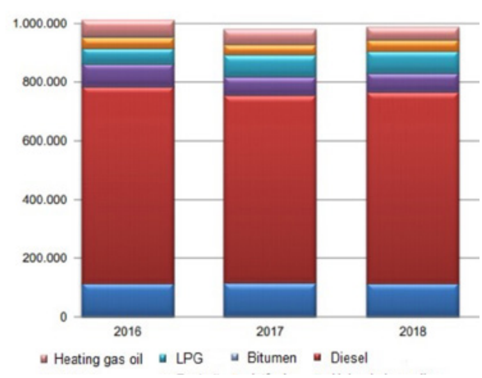
The Energy Market

Oil and Petroleum Products

Oil Supply and Demand

On the basis of the data presented in ERC's Annual Reports 2016 – 2018, the total imported quantities of oil in North Macedonia in 2018 were 0.988 mt, which is about the same as the imported products of oil derivatives in 2017 (0.981 Mt) and 2016 (1.010 mt) (Figure 5.193).

Figure 5.193 **Import of oil derivatives in North Macedonia for 2016, 2017 and 2018 (tons/annually)**

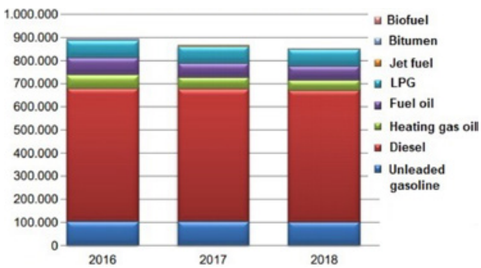


Source: ERC Annual Reports 2016 - 2018

15 http://www.stat.gov.mk/PrikaziSoopstenie_en.aspx?rbrtxt=64

In 2018 the largest import was diesel fuel, 66% of the total import, next are unleaded gasoline types with 11.45%, LPG with 7.39%, fuel oil with 6.65%, heating gas oil with 4.45%, jet fuel with 3.98% and a small percentage of biogas fuel. Oil derivatives were imported from 18 countries, whereby the majority from neighbouring countries: from Greece with 80.31%, Bulgaria with 11.80%, Serbia with 3.46% and Albania with 1.43%. The export of oil derivatives in 2018 was 0.140 mt, which is a small increase from 0.117 mt in 2017. In 2018 there were 0.852 mt of oil derivatives sold at the domestic market, which represents a small decrease compared to previous years, as shown in Figure 5.194.

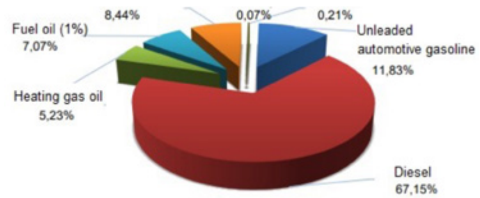
Figure 5.194 **Sale of oil derivatives in North Macedonia in 2016, 2017 and 2018**



Source: ERC Annual Reports 2016 - 2018

Figure 5.195 presents the share of oil derivatives in the total domestic consumption of oil derivatives in 2018, which in 2018 was dominated by diesel fuels. The largest consumers of petroleum products in 2018 were transport with 0.701 mt and industry with 0.129 mt.

Figure 5.195 **Share of oil derivatives in the total domestic consumption of oil derivatives in 2018**



Source: ERC Annual Reports 2016 - 2018

Oil Imports / Dependence, and Security of Supply

North Macedonia is 100% reliant on the import of petroleum products since 2013 and it does not have any confirmed commercial crude oil reserves. The import takes place by road from the surrounding countries, guaranteeing diversified supply sources and security of supply. Like other countries, North Macedonia is obliged to maintain petroleum products reserves in the size that corresponds to no less than 90 days of average daily net imports, or 61 days of average daily consumption, whichever is greater. In 2018, the oil stock corresponded to 65 days, a 5 day decrease from 2017 reserves.

The government has transposed the Directive 2009/119/EC on compulsory oil reserves in the national Law on Compulsory Oil Reserves[16] and has prepared all requested secondary legislation. The Compulsory Oil Reserves Agency is responsible for the establishment, maintenance, storage and sale of compulsory oil and petroleum products reserves. However, the application of the new legislation has been postponed for 1 January 2021, while the compulsory oil reserve goals are to be met by 31 December 2022. According to the Action Plan[17]. North Macedonia aims to hold 70% of required reserves in the country and 30% in EU countries.

Upstream Sector- Domestic Production and Exploration

The oil sector in North Macedonia currently consists of wholesale trade in oil and petroleum products and biofuels, storage and trade of oil and petroleum products as well as retail trading in petroleum products and biofuel. The upstream sector practically does not exist. Possible petroleum plays in the eastern part of the country are mentioned, but exploration has not started yet.

Downstream and Midstream Sectors Infrastructure

The only oil refinery in North Macedonia is OKTA[18] in Skopje. Its majority shareholders

[16] Law on Compulsory Oil Reserves, Official Gazette No.144/2014, 178/2014, 199/2015, 197/17, 7/19 and 275/19
[17] Strategy for Energy Development until 2040, Official Gazette of North Macedonia No. 25/20, [Online]. Available: http://www.economy.gov.mk/Upload/Documents/Adopted%20Energy%20Development%20Strategy_EN.pdf

are Hellenic Petroleum Group. The average capacity of OKTA is 2.5 Mt/year, or 5,480 bbl/day. The maximum production of the refinery was 1.36 Mt petroleum products in 1988. The total storage capacity of OKTA is about 380,000 m^3. [19]

The installations of OKTA are connected with the Hellenic Petroleum refinery in Thessaloniki through a 213.5 km pipeline with capacity of 2.5 Mt/year. The pipeline operator is Vardax SA, a company whose major shareholder is Hellenic Petroleum Group, while the government of North Macedonia retains 20% of shares. The OKTA refinery stopped production in January 2013, because of unfavourable conditions in the international oil market. However, now it is the biggest importer and trader of petroleum products in the country. Private company Makpetrol from Skopje possesses the biggest biodiesel refinery in the country, with a capacity of 0.03 Mt/year. The refinery started operation in 2007 and it uses unrefined oil from oil rape seed[20]. In addition, there are three very small biodiesel refineries.

At the end of 2018, there were approximately 330 petrol stations in North Macedonia. Makpetrol owns 127 of these, Lukoil Makedonija 30 and OKTA 26 stations, while the remaining 147 petrol stations are privately owned by several domestic small companies[21]. The prevailing practice is that companies which possess petrol stations also participate in the wholesale market of petroleum products. The total storage capacity for oil and petroleum products in North Macedonia is approximately 382,000 m3. The biggest contributors in this respect are capacities provided by the OKTA refinery, Makpetrol and Lukoil Makedonija, as well as, the State Stock Reserves. However, the new Energy Development Strategy states that the storage condition and purpose could be improved: "Major concern is the condition of the storage units and their applicability for compulsory oil stocks. In addition, certain part of these capacities is used by traders of petroleum products for their operational reserves as obliged by the Energy Law."[22]

Planned New Projects

The new Energy Development Strategy has projected growing consumption of petroleum products in all considered scenarios, which would create a need for larger volumes of storage capacities in future. Therefore, the main recommendation is that the country should ensure availability of necessary infrastructure for stock keeping via Action Plan. The Action Plan should define the dynamics of formation of reserves until 31 December 2022, necessary storage volumes per product, location of storage capacities, roadmap to achieving necessary storage capacities, and financing options considering the impact on the final consumers.[23]

Natural Gas

NG Supply and Demand (in bcm)

According to the data of the State Statistical Office and ERC, the total supply/imports of natural gas in North Macedonia rapidly increased during the last few years, as shown in Figure 5.196 reached 0.215 bcm in 2016, 0.276 bcm in 2017 and 0.255 bcm in 2018. The monthly quantities of supply/imports in 2016, 2017 and 2018 are presented in Figure 5.197.

Figure 5.196 **Supply/import of natural gas in the period 2004 - 2018**

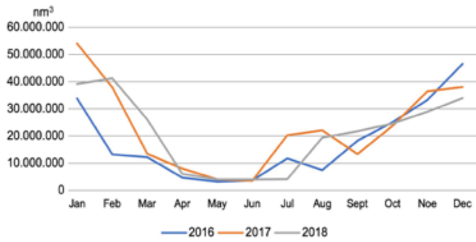
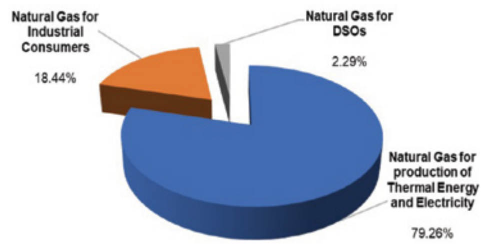
Figure 5.197 **Monthly supply/import of natural gas in 2016, 2017 and 2018**



Source: ERC

Figure 5.198 **Consumption of natural gas by consumer type in 2018**



Source: ERC

As shown in Figure 5.197, the largest consumption of natural gas occurs during the winter months, which is expected considering that natural gas is mostly used for production of thermal energy. During July and August there is a consumption deflection which is due to the operation of CHPP TE-TO, followed by significant increase in the winter period when TE-TO and few smaller CHPP operate in full capacity. The industrial consumers which are using natural gas for their processes and operate all year round define the minimum consumption.

Natural gas consumption in North Macedonia is dominated by combined heat and power production plants and thermal power plants. Their portion in the final natural gas consumption for 2018 was 79,26%. Next are the industrial consumers with 18,44% market share, where the dominant role belongs to the metal industry. At the end are the distribution companies with a share of 2,29% (Figure 5.198).

NG Imports (in bcm), Dependence (%)

North Macedonia is 100% dependent on natural gas imports. Almost the entire supply of gas is imported from Russia through the only entry point at the Bulgarian border. The distribution network in the city of Strumica is not connected with the transmission network and supply is ensured by truck transport of compressed natural gas (CNG) from Bulgaria.

Domestic Production and Exploration

There is neither domestic gas production nor on going gas exploration in the country.

Infrastructure (Pipelines, Storage)

The international Corridor 8 is the most significant import infrastructure, entering the country in Deve Bair. The national master pipeline, from Deve Bair, is extended further to Kriva Palanka, Kratovo, Kumanovo and Skopje (bold blue line in Map 5.49). Its total length is about 98 km and its capacity is 0.8 bcm/year,

Map 5.49 **Existing (in bold) and planned natural gas infrastructure in North Macedonia**

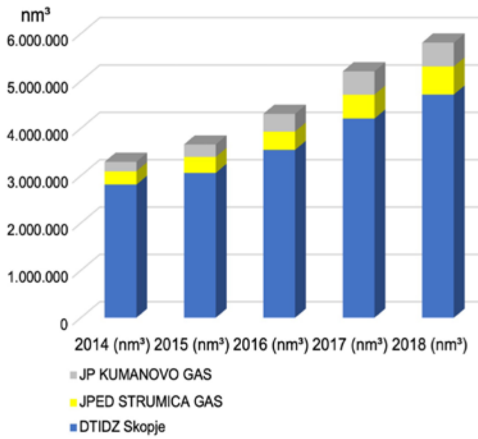
Source: ERC, Annual Report 2018

with possibility for upgrade up to 1.2 bcm/year. Only up to 80% of the existing capacity is used during some winter days, while the daily utilization in the summer months is very low and ranges from 5% to 15%.

In North Macedonia, there are three developed distribution systems for natural gas:
- Town of Strumica, with a length of 28.50 km
- Town of Kumanovo, with a length of 13.14 km
- Technology-Industrial Development Zone (DTIDZ) of Skopje, with a length of 5.20 km.

The natural gas distribution systems are constantly being developed and upgraded. Distributed natural gas volume in their systems is minor, although there is noticeable ongoing growth. The largest portion of distributed gas is in the DTIDZ where there are several industrial consumers using natural gas in the production processes, as well as for heating. A breakdown of distributed natural gas by systems in the period 2014 - 2018 is given in Figure 5.199.

Figure 5.199 **Natural gas quantities in the distribution systems by years and distribution companies**



Source: ERC, Annual Report 2018

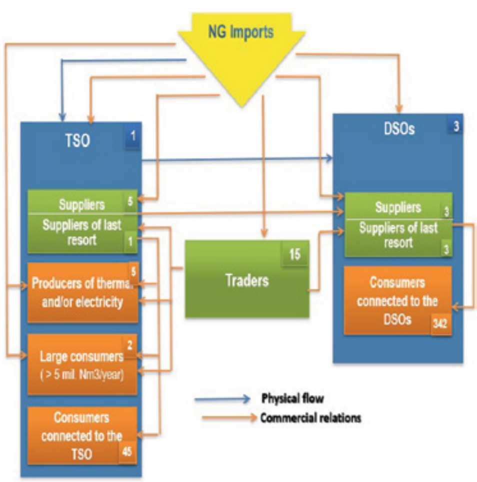
At this stage of gasification in the city of Skopje, there is practically no distribution network. Several existing customers, which are the largest consumers of natural gas in the country, are directly connected to the transmission network. However, there are plans and activities for Skopje's distribution network development.

Domestic Gas Market

The natural gas market is governed by the Energy Law of 2018, which essentially transposes the TPEGM. The corresponding secondary legislation is also in place and greatly implemented, with an exception of ownership unbundling and certification of the Natural Gas TSO, GA-MA[24]. The certification is frozen by a long-lasting dispute on the majority ownership over the gas transmission system between the Government and Makpetrol, who currently both own 50% of shares in GA-MA.

The natural gas market in North Macedonia is fully liberalized as of 01 January 2015. Since then, no natural gas disruptions have been noticed. The structure of the market is presented in Figure 5.200.

Figure 5.200 **Overview of the natural gas market in North Macedonia in 2018**

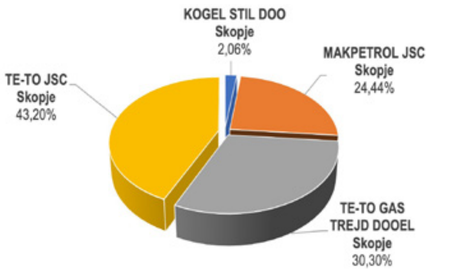


Source: ERC, Annual Report 2018

The market share of the traders and suppliers in the wholesale natural market is displayed in Figure 5.201, while the shares in the retail market can be observed in Figure 5.202.

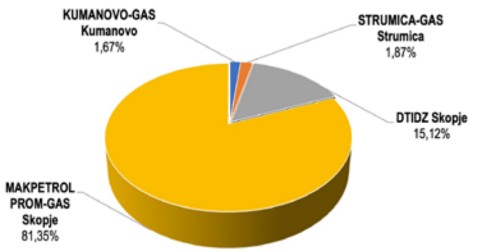
[24] http://www.gama.com.mk/Default.aspx

Figure 5.201 **Market share of traders/suppliers at the wholesale natural gas market in 2018**



Source: ERC, Annual Report 2018

Figure 5.202 **Market share of the suppliers at the retail natural gas market for 2018**



Source: ERC, Annual Report 2018

Makpetol Prom-Gas supplies natural gas to consumers connected to the gas transmission system, while DTIDZ Skopje, Kumanovo Gas and Strumica Gas supply natural gas to consumers of the gas distribution systems respectively. DTRIZ Skopje and Kumanovo Gas purchase natural gas from Makpetol Prom-Gas.[25]

National NG Policy –Strategic Plan

Natural gas is expected to play an important role in replacing coal and as a bridge fuel to 2050. There is an ambitious gasification plan, which includes interconnections with Greece and other countries. As projected by the Energy Development Strategy, the overall consumption of natural gas will constantly increase in the long term, with average annual rate of 3.6%-4.1% depending on the success of implementing EE and RES measures[26].

In order to meet these requirements, the Government has developed a very ambitious national strategic plan for natural gas. The strategic plan is twofold and includes:

- Connection of North Macedonia to major international gas corridors;
- Development of national transmission and distribution grids.

The planned development of the national transmission network for natural gas complies with the expected consumption needs in particular parts of the country. Some of the smaller towns in the country are envisaged to be supplied through so called "virtual pipelines". The expansion of the gas network is to be financed through the State Budget and EIB and EBRD credit lines. The state-owned JSC National Energy Resources (NER)[27] is in charge of the above projects.

Planned new projects

The interconnection with Greece, which is on the Projects of Mutual Interest (PMI) list [28] and is expected to be completed by 2022, is identified as the key project that will diversify supply. It will connect North Macedonia to the Trans Adriatic Pipeline (TAP) which brings natural gas from the Caspian region to Europe. In addition, NER is involved in the Central and South East Gas Connectivity (CESEC) initiative. Under it, a Memorandum of Understanding (MoU) was signed in Dubrovnik in 2015 that includes projects for interconnectors between North Macedonia, Greece and Bulgaria. There is also potential for five other interconnections with Serbia, Albania, Kosovo, Bulgaria and Greece (link with Bitola). The interconnector with Serbia is in the current PECI/PMI list too.

As reported by ERC, there are also several magistral pipelines under construction, with total length of 204 km (phase I), and due to be completed by the end of 2020. Those are:

- Stip – Negotino – Bitola (81% completed by the end of 2019); and
- Skopje – Tetovo – Gostivar (57% completed by the end of 2019).

[25] ERC, Annual Report 2018
[26] Strategy for Energy Development in North Macedonia for the period until 2040
[27] http://mer.com.mk/en-US
[28] https://www.energy-community.org/regionalinitiatives/infrastructure/selection.html

In phase II of the development of national magistral network, NER plans to construct the following pipelines:

- Magistral gas pipeline, section Gostivar – Kichevo (due in 2022),
- Magistral gas pipeline, section Kichevo - Ohrid (due in 2025).

Furthermore, in order to provide development and renewal of the natural gas transmission system, as well as development and expansion of the gas transmission pipeline grid, NER has also planed the following activities, for the period from 2019 to 2023:

- Expansion of the city gas pipeline network in Skopje for the connection of new consumers;
- Completing the gas pipeline ring along with distribution lines for connecting interested consumers in the City of Skopje,
- Construction of a new connection to the magistral gas pipeline for the needs of CHPP TE-TO in order to increase its operating efficiency;
- Implementation of SCADA system over the gas transmission network for measurements and detection of losses.

Solid Fuels

Supply and consumption

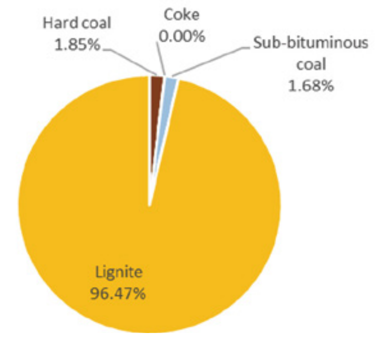
According to the State Statistical Office data, the balance of solid fuels including production, import, stock change and export, the sums of which coincide with the total consumption of primary energy (gross inland consumption) during the period 2015 - 2018 is presented in Figure 5.203.

Figure 5.203 **Production of solid fuels, net imports, net exports and variations of reserves in North Macedonia, during 2015 - 2018**

Source: Information collected from the official page of the State Statistical Office

The production consists only of lignite with its rather low calorific value and a decrease of production over recent years is evident. The total primary production of lignite in 2018 was 4.994 mt and it was almost completely (95%) used for electricity production in TPPs. The other types of fuels (hard coal, coke and sub-bituminous coal) composing the gross inland consumption (4.911 mt in 2018) regularly come from import. However, their shares are very small in comparison to the share of lignite (Figure 5.204).

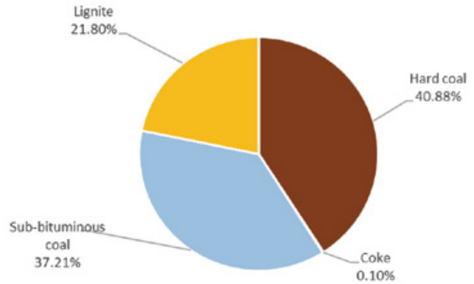
Figure 5.204 **Gross inland consumption of solid fuels by type in 2018**



Source: Information collected from the official page of the State Statistical Office

In 2018, after using lignite for electricity production and filling a stock gap of lignite, about 0.221 mt (4.5% of gross inland consumption) remained available for final consumption. The shares of individual types of solid fuel in the final consumption are shown in Figure 5.205. The biggest final consumer of solid fuels with 0.207 mt was the industrial sector.

Figure 5.205 **Solid fuels available for final consumption of by type in 2018**



Source: Information collected from the official page of the State Statistical Office

Local production and exploration

Out of all fossil fuels, North Macedonia disposes and exploits only low calorific coal - lignite. All other fossil fuels, such hard coal and sub-bituminous coal, are provided through imports. Existing lignite mines in the country are divided into two groups, according to the intended use: (a) production of electricity, which includes surface mines owned by TPPs of the biggest electricity production company in the country (state owned) Power Plants of North Macedonia (ESM). These are Suvodol, Suvodol-Low Basin (LB), Brod-Gneotino (TPP Bitola) and Oslomej (TPP Oslomej); and (b) retail trade and consumption, consisting of surface mines BRIK Berovo and Drimkol-lignite, which are minor.

Deposits

The rest of lignite deposits in North Macedonia consist of the following sites: Zivojno, Mariovo, Popovjani, Negotino, Lavci-Resen, Pancharevo-Pehchevo, Zvegor-Delchevo and Priskupshtina. Table 5.149 provides information on the exploitation reserves of these deposits in 2014. The only important deposits are Mariovo and Negotino, whose thermal capacity accounts for 28% and 18% of total, respectively.[29]

Since 2014, there have not been any important developments in the opening of new mines and state deposits, except that the mines owned by ESM are continuously exploited in the meantime. As a result of this exploitation, Oslomej mine is nearly depleted of its resources and mines of TPP Bitola (Suvodol, Suvodol – Low Basin (LB), Brod-Gneotino) are sufficient to provide life to TPP Bitola up to 2030.

Table 5.149 **Assumed deposits of lignite available for exploitation in North Macedonia in 2014**

Deposit	Exploitation reserves	Low Calorific	Available capacity	Thermal	Annual exploitation
	[mt]	[kJ/kg]	[PJ]	[%]	[mt]

Source: Draft Strategy for Energy Development in North Macedonia for the period until 2035

Coal imports

As reported by the State Statistical Office, a total of 0.214 mt of coal was imported in North Macedonia in 2018, of which: 0.101 mt hard coal, 0.0003 mt of coke, 0.092 mt of sub-bituminous coal and 0.020 mt of lignite. As it can be observed in Table 5.149, the imports are rather steady in the past years and there are no prospects than increasing in the near future.

Planned new projects

With the Program for implementation of the Strategy for Energy Development in North Macedonia for the period 2013 – 2017 there were several lignite projects proposed (mainly in support of operation of TPP Bitola). A new program is currently under preparation by the Ministry of Economy of North Macedonia. However, the new Energy Development Strategy of 2020 completely changes considerations on energy sector development by focusing on possibilities for decarbonization of the energy sector and transition to green

[29] MANU, Draft Strategy for Energy Development in North Macedonia for the period until 2035

energy by decommissioning of existing lignite TPPs in near future. Therefore, at this stage, investments in new lignite mines look rather uncertain. The only lignite mine opening project, as considered in the Reference scenario of the new Energy Strategy, is Zivojno. This site is located near TPP Bitola and according to ESM's 5-year investment plan 2018-2022, the commissioning of new Zivojno mine could extend the coal supply to TPP Bitola for about 10.6 years.

Electricity

The reform of the North Macedonian electricity sector continued towards fulfilling the requirements of the Third Package for Electricity and Gas Markets (TPEGM) with the adoption of the new Energy Law in 2018[30]. The EnC represents the main agreement in force with EU acquis requirements and following decisions of the Permanent High-Level Group of the EnC, all Contracting Parties are obliged to transpose the acquis from some of the EU Network Codes (NCs). This specifically includes connection NCs and the NC on wholesale energy market integrity and transparency. ERC, introduced above, is the National Regulatory Authority in charge of the electricity sector.

Most of the incumbent generation is concentrated in the single state-owned company JSC Power Plants of North Macedonia (ESM)[31]. Then, the North Macedonian Electricity Transmission System Operator (MEPSO)[32] owns and operates the high-voltage network. MEPSO founded the Electricity Market Operator of North Macedonia – MEMO in October 2018, which, although it is under its umbrella, is separate from the transmission business. EVN Skopje JSC[33] has 4 daughter companies active in the electricity sector, adhering to unbundling requirements.

Elektrodistribucija is the largest distribution system operator with its network covering 99.9% of the country, EVN Home performs public supplier functions, EVN Supply is active on the open market, and EVN Power Plants owns and operates medium and small hydro power plants with a total capacity of 87.81 MW. Finally, the ESM subsidiary Energetika contains a vertically integrated DSO, which operates on a very limited territory of Skopje's industry complex Zelezarnica. It serves a small number of light industrial and commercial customers, for which it holds a license granted by the ERC.
Besides the Energy Law provisions, North Macedonia's wholesale electricity market is also governed by the current Market Rules. The percentage of market liberalisation in 2018 was 47.26 % according to the ERC. The previous year, this percentage was estimated at 39.75 %, which signifies a solid step towards opening up the market. Supplier switching is another good indicator of market competition. ERC registered 4,344 changes of supplier in 2018, which represents 20.13 % of the total number of consumers on the liberalised market. Furthermore, this is an increase of 36.68 % compared to the previous year (3,299 supplier changes).

The year 2019 was significant for market liberalisation, because the previous stepwise liberalisation plan was abandoned, and all customers became eligible customers on 1 January. The former Supplier for tariff customers[34] in North Macedonia ceased to operate on 1 July 2019, when the newly established suppliers securing the provision of universal service in compliance with the TPEGM and the Energy Law took over. The new regulated suppliers are the universal supplier and the supplier of last resort, and the company to perform these two regulated supply activities is EVN Home, a subsidiary of EVN Skopje JSC, which won the public tender, transparently open for that purpose.

30 Energy Law, Official Gazette of the Republic of North Macedonia, No. 96/18 and No. 96/19, [Online]. Available only in local language: http://www.erc.org.mk/pages.aspx?id=8
31 http://www.elem.com.mk/en/Elem.asp
32 http://www.mepso.com.mk/en-us/Default.aspx
33 http://www.evn.com.mk/
34 Until 1 January 2019, according to the previous Energy Law, tariff customers were only households and small commercial customers with less than 50 employees and less than 10 million Euros annual revenue in the last two fiscal years and which had consumed less than 100 MWh electricity in 2017. The rest of the electricity customers were by Law mandatory sent to the open electricity market, previously.

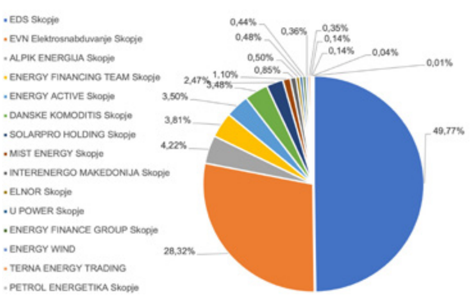
The services of the universal supplier are available for households and small commercial customers with less than 50 employees in the last two fiscal years and less than 2 million Euros annual revenue, who have not selected or have terminated their contract with a supplier on the open market. The universal supplier services can be used for three months at most.

Electricity Supply and Demand

Eligible consumers were able to choose from 18 suppliers and traders in 2018. Their market shares are represented in the Annual Report 2018 of Energy and Water Services Regulatory Commission (ERC).

Energy Delivery Solutions (EDS) has a significant share of the supply and, in addition, it is the responsible party for the balancing market serving multiple producers with a total installed capacity of 320 MW. The supplier is also active in other markets in South Eastern Europe and is a member of the Hungarian Power Exchange. Since 13 April 2018, EDS operates as a subsidiary of the Greek company Public Power Corporation (PPC). The acquisition was reportedly worth 4.8 million Euro.

Figure 5.206 **Market shares of active electricity suppliers in 2018**



Source: ERC, Annual Report 2018

Table 5.150 shows electricity procurement of the largest electricity supplier for household and small consumers in North Macedonia in 2018, according to the ERC report. The data refers to EVN, as it was performing the function of supplier of tariff consumers in 2018. The majority of these customers are expected to remain with EVN and be supplied with electricity by the newly formed EVN Home, therefore it may be relevant to foresee the future operation of the major supplier.

Table 5.150 **Electricity procurement by EVN Macedonia for the purposes of supplying tariff and small consumers in 2018**

Producer/trader	Amount (MWh)	Price (€/MWh)	Value €

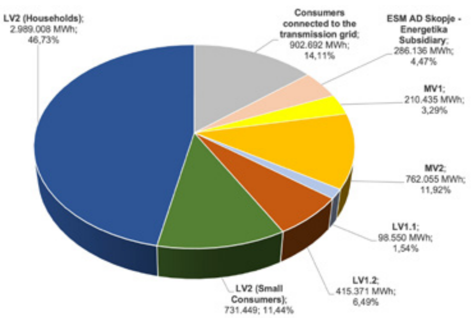
5.	Total electricity consumption (1+3)	6,455,211	6,377,254	6,365,196	-1.39	-0.19

Source: ERC, Annual Report 2018

Figure 5.208 **Structure of consumer categories in total electricity consumption in 2018 (in MWh and % share)**



Source: ERC, Annual Report 2018

Compared to 2017, electricity losses in the transmission grid in 2018 increased by 12.8 % due to increased transit. Nevertheless, the losses percentage was 1.8 %, which is sufficiently below the allowed maximum of 3 %. While in the distribution grids, the electricity loss percentage was 14.2 %, which is over the allowed 13.4 %.

Installed Capacity

The electricity generation portfolio of North Macedonia comprises both hydro and thermal production capacities. It also includes one wind farm and a number of smaller RES installations. The main electricity companies are ESM, TETO[35] and EVN Power Plants, while the rest are smaller hydro plants and various RES plants.

ESM is the largest producer in North Macedonia. The total installed capacity of its power plants is 2,076 MW. It owns and operates 49.8 % of the

[35] http://te-to.com.mk/en_US/

thermal power capacity in the country (Bitola 1,2,3 and Oslomej), two CHP plants (Energetika and KOGEL), eight hydro plants and the wind farm at Bogdanci. Its role as regulated power producer will undergo a stepwise downward reduction as prescribed by the new Energy Law. ESM is obliged to offer the following quantities of electricity to the universal supplier:

(1) in 2019 at least 80% of the total annual needs of the supplier;
(2) in 2020 at least 75% of the total annual needs of the supplier;
(3) in 2021 at least 70% of the total annual needs of the supplier;
(4) in 2022 at least 60% of the total annual needs of the supplier;
(5) in 2023 at least 50% of the total annual needs of the supplier;
(6) in 2024 at least 40% of the total annual needs of the supplier;
(7) in 2025 at least 30% of the total annual needs of the supplier.

Furthermore, with the still governing balancing rules, ESM has exclusivity rights to reserve and balancing provision. This will be abandoned very soon with the new balancing rules. However, it is questionable if a real competition will be open in this respect, as besides ESM, the only generator in the country which has technical capabilities for provision of ancillary services is CHPP TE-TO. The largest production capacity is TPP Bitola, located in the south-western part of the country, with 675 MW of installed power capacity. The plant is undergoing a process of modernisation, currently in its third and fourth phase, which include fitting new electrostatic filters and cooling towers (in the stages of procuring materials). It is expected that the project will be completed in the beginning of 2021. TPP Oslomej near Kichevo has an installed capacity of 125 MW. Due to the nearly depleted resources in nearby mines, the plant is awaiting decision on its future, i.e. decommissioning or changing the fuel supply. ESM will make that decision in line with the recommendations from the new Governmental Strategy.

TPP Negotino, with an installed capacity of 210 MW is used exclusively for cold reserves because it uses heavy fuel oil and the production is uneconomical. TETO in Skopje is the largest combined heat and power plant, with an installed capacity of 220 MW for electricity and up to 160 MW for heat production.

The bulk of the hydro power is located in the western part of the country, utilizing the potential of the river basins of Vardar, Crn Drim, Radika and Treska. The Mavrovo Hydro Power System includes three power plants: HPP Vrutok, HPP Raven and HPP Vrben, with total installed capacity of 214 MW and represents one of the largest and the most complex hydro power systems in North Macedonia. HPP Shpilje (84 MW) and HPP Globochica (42 MW) are located in the river basins of Crn Drim and Radika.

Map 5.50 **Location of power plants owned by ESM**

Source: www.elem.com.mk

HPP Kozjak and HPP Sv. Petka, with an installed capacity of 88 MW and 36 MW respectively, make the hydro cascade in the river Treska, near Skopje. HPP Tikves, with an installed capacity of 116 MW, is located in the river basin of Crna Reka, in the central part of the country Finally, the wind farm at Bogdanci with an installed capacity of 38 MW is located in the north-east.

The locations of these larger power plants are shown in Map 5.50. Table 5.152 summarizes electricity generation in 2016, 2017 and 2018, while the information for 2018 is presented in the pie chart in Fig. 5.210.

Table 5.152 **Electricity generation in North Macedonia in 2016, 2017 and 2018**

		Generation (MWh)			2018/2016	2018/2017

Planned New Capacity – Investments

According to the latest ECR report the following investment were approved for ESM in 2017 and 2018:

Table 5.153 **ERC approved investment for ESM (in MKD)**

Power Plant	**2018**	**2017**
Hydro power plants	453.794.181	153.927.152
REK Bitola total	3.109.969.437	2.955.263.064
Thermal power plant Bitola	1.071.469.437	638.034.064
Mines Bitola	2.038.500.000	2.317.229.000
REK Oslomej total	737.748.114	52.819.865
Thermal power plant Oslomej	737.748.114	52.819.865
Mine Oslomej	0	0
Total	4.301.511.732	3.162.010.081

Source: ERC, Annual Report 2018

None of the funds are allocated for capacity expansion, and no such plans have been announced by ESM or private investors. This excludes small hydro plants and RES, which are covered in the next section.

Electricity Imports – Exports

North Macedonia has a relatively high import dependency. Despite the declining consumption, the average share of imports is around 30% of total electricity consumption. Specifically, in 2018, domestic generation supplied 69.02 % of total demand, while 30.98 % was supplied through imports. However, there was a 21.35 % increase in electricity exports in 2018 compared to 2017, and an increase of 136.11 % compared to 2016. The details are summarised in Table 5.154.

Tariffs

In 2018, electricity prices for residential customers and public lighting were regulated, while commercial and agriculture customers could be regulated or liberated depending on their size. The average regulated prices in 2018 excluding additional charges were:

- Residential: 2.19 MKD/kWh or 35.58 €/MWh
- Public lighting: 4.48 MKD/kWh or 72.83 €/MWh
- Regulated 'small' commercial: 6.79 MKD/kWh or 110.36 €/MWh

The average price on the wholesale electricity market in 2018 was 3.46 MKD/kWh, or 56.73 €/MWh, which corresponds to an increase of 14.57 % to the previous year. Furthermore, industrial customers were supplied on the open market with an average price of 3.53 MKD/kWh or 57.36 €/MWh, an increase of 12.42 % compared to 2017. Lastly, the 2018 average price for 'large' commercial customers increased by 23.91 % from 2017, reaching 3.42 MKD/kWh or 55.55 €/MWh.

Table 5.154 **Electricity imports and exports in North Macedonia in 2016, 2017 and 2018**

	Electricity (MWh)			**2018/2016**	**2018/2017**
	2016	**2017**	**2018**	**% difference**	**% difference**
Exports from domestic generation	159.853	311.026	377.423	136,11	21,35
Declared imports	2.190.606	2.293.571	2.297.169	4,86	0,16
Total electricity sold on regulated and open market	7.414.899	7.360.299	7.415.009	0,00	0,74

Source: ERC, Annual Report 2018

Besides VAT of 18%, the following additional charges applied in 2018:

- Transmission network tariff: 0.2053 mkd/kWh or 3.30 €/MWh
- Elektrodistribucija (DSO) distribution network tariff: 1.4084 mkd/kWh or 23 €/MWh
- ESM Energetika (DSO) distribution network tariff: 0.2258 mkd/kWh or 3.70 €/MWh
- Electricity market organisation and operation tariff: 0.0018 mkd/kWh or 0.03 €/MWh

Cross-Border Interconnections

The 400 kV transmission lines are the backbone of the transmission grid in North Macedonia and provide interconnections to the neighbouring power systems. The 110 kV transmission grid is the most outspread one and connects the large hydro power plants, all of the larger populated places, as well as the industrial centres.

Map 5.51 shows the current transmission network with its interconnections.

The 400 kV transmission lines SS Skopje 5 – SS Kosovo B and SS Stip – SS Nis interconnects the north part of the grid to Kosovo and Serbia, respectively. With the Greek electricity system, the interconnection is realized via two 400 kV transmission lines: SS Bitola 2 – SS Florina and SS Dubrovo – SS Thessaloniki. In 2009 the transmission systems of North Macedonia and Bulgaria were synchronously connected, after completing the 400 kV transmission line SS Stip – SS Crvena Mogila.

Transmission rights on interconnectors in North Macedonia are granted in the form of Physical Transmission Rights. The allocation on the borders with Serbia and Bulgaria are carried out bilaterally, while coordinated capacity allocation is performed on the North Macedonian-Greek border by SEE CAO.

Map 5.51 **The Transmission network of the Republic of North Macedonia in 2019**

Planned New Projects

The electricity infrastructure part of Corridor 8 (East-West) will be fully completed by interconnecting the Albanian Power System on the west, after completion of the 400 kV interconnection project Bitola - Ohrid - Elbasan. This project is underway. It includes construction of a new 400 kV line and a new 400/110kV substation in Ohrid. The future topology of the North Macedonian transmission network, according to MEPSO's development plan, is shown in Map 5.52. In general, the transmission grid operates with satisfactory safety, reliability and security parameters. Certain weaknesses of the grid were identified in the Ohrid region related to reactive power and voltage support due to the old topology of the 110 kV grid. It is expected that completion of the project for the new 400/110 kV SS Ohrid will mitigate these issues.

Renewables

Overview of Sector's Development

The Renewables sector in North Macedonia is also governed by the Energy Law. It prescribes adoption of a new Strategy on Energy Development and Action Plan for Renewables in which the energy policy of North Macedonia for the following 20 years shall be determined, including the potential of RES and necessary measures for support. In the meantime, strategic decisions are based upon the previously adopted Action Plan for RES from 2015[36] and the Action Plan for Amending the Action Plan for RES from 2017[37].

The potential for RES capacity in the country is estimated as part of the Action Plan for RES. It follows the most likely scenario for RES development in North Macedonia, indicating the realistic potential to develop each RES type until 2025. Table 5.156 and Table 5.157 present the realistic potential, and therefore projected RES installed capacity and electricity generation until 2025.

These projections are taken into account in the Decision on the mandatory national targets for RES[38], brought in February 2019, that defines national targets as:

[36] Ministry of Economy of North Macedonia, Action plan for development of renewable energy sources until 2025 with a vision until 2035, Official Gazette of the Republic of North Macedonia, No. 207/15., November 2015.

[37] Ministry of Economy of North Macedonia, Action plan for amending the action plan for development of renewable energy sources until 2025 with a vision until 2035, April 2017, Official Gazette of the Republic of North Macedonia, No. 51/17.

[38] Government of North Macedonia, Decision on the mandatory national targets for renewable energy sources, February 2019, Official Gazette of the Republic of North Macedonia, No. 29/19., Available only in local language

• 23 % RES participation in the total electricity consumption by 2020
• 10 % RES participation in the total electricity consumption in the transport sector by 2020.

Table 5.156 **Historical and potential RES installed capacity in MW in North Macedonia from 2016 until 2025**

Latest Legislation, Incentives and National RES Policy

The current policy regarding support for RES investments is based on Feed-in Tariffs (FIT) and Feed-in Premiums (FIP). The latter is prescribed in the Energy Law of 2018, and is therefore a newly implemented support scheme in North Macedonia.

The support schemes are explicitly defined in the Decree on the Measures for Support of Electricity Generation from Renewable Energy Sources[39]. It defines FIT as a guaranteed price for the energy produced by an eligible energy source under a contract, while FIP represent a fixed premium to the price per kWh at which the producer has sold its energy on the wholesale market. In case the producer is unable to sell on the market, the energy produced shall be bought by either a trader or supplier previously nominated by the MoE. The eligible technologies for FIT are:
• Hydro power plants no larger than 10 MW
• Wind power plants no larger than 50 MW
• Biomass power plant no larger than 1 MW
• Biogas power plant no larger than 1 MW
Whereas, FIP eligible technologies are:
• Wind power plant no larger than 50 MW
• Solar PV power plant no larger than 30 MW

In addition to FIT and FIP, RES producers enjoy other benefits and preferential treatment. For instance, producers contracted under the FIT scheme are guaranteed to sell all energy they produce and are therefore not balancing responsible parties. This responsibility is taken on by the MO. Producers under the FIP scheme do not benefit from this treatment. Then, the TSO and DSOs are obliged to grant priority access and dispatch to RES producers and highly efficient combined heat and power plants in an objective, transparent and non-discriminatory manner and under the conditions set out in the network codes. Priority access and dispatch may only be suspended in cases of risks to system security of supply, and the corresponding operator must notify the ERC of the reasons.

[39] Government of North Macedonia, Decree on the Measures for Support of Electricity Generation from Renewable Energy Sources, February 2019

Table 5.158 below summarizes the duration and level of support available to RES plants under these two support schemes.

Table 5.158 **Information on the level of support and duration by type of RES**

RES type	Level of support (€¢/kWh)[40]	Duration of support (years)
Feed-in Tariffs		
Hydro (kWh/month)		
≤ 85000	12.00	
> 85000 and ≤ 170000	8.00	20
> 170000 and ≤ 350000	6.00	
> 350000 and ≤ 700000	5.00	
> 700000	4.50	
Wind	8.90	20
Biomass	15.00	15
Biogas	18.00	15
Feed-in Premiums		
Wind	Auction	20
Solar PV	Auction	15

Source: Government of North Macedonia, Decree on the Measures for Support of Electricity Generation from Renewable Energy Sources, February 2019

In February 2019, the Government also brought a Decision on the Total Installed Capacity of Preferential Electricity Producers[41]. It defines the limits on capacity that can be contracted under the FIT or FIP scheme, and by extension it sets out the budget for the FIT scheme.

In particular the capacity limits for FIT are:
• 86 MW for wind power plants
• 10 MW for biomass power plants
• 20 MW for biogas power plants
- 7 MW until 31 December 2019
- 13 MW after 1 January 2020

Under the FIP scheme, Solar PV installed capacity is limited to 200 MW. In addition, the Programme for Financial Support of Preferential Producers under Feed-in-Premium Scheme[42] defines the budget for the FIP scheme to be 30 million MKD, roughly equivalent to around 490,000 Euro.

Lastly, the maximum reference value of the fixed premium for PV in 2019 was 15€/MWh. Wind power capacity was not covered by the Decision or Programme because the government did not have plans to open a tendering procedure for this type of RES during 2019.

Installed Capacity per Source

The data on installed RES capacities and generation in 2018 per type of RES is released by the ERC in their annual report, and it is summarised in Table 5.159.

Table 5.159 **Types of Renewable Energy Sources**

	RES type	Installed capacity (MW)	Electricity generation (TWh)
1	Wind onshore	36.8	0.097
2	Wind offshore	0	0
3	Solar PV	18.49	0.023
4	Solar thermal	0	0
5	Hydro		
5.a	Small hydro	106.32	0.214
5.b	Large hydro with reservoir or run-of-river	586.65	1.625
6	Biomass		
6.a	Bio-solids	0	0
6.b	Biogas	7	0.054
6.c	Waste	0	0
7	Geothermal	0	0

Planned New Major Projects

With the new support mechanisms, the number of RES investment projects in North Macedonia is expected to increase in the following years. Nevertheless, there are a few confirmed and currently ongoing RES investment projects:

(1) The wind park Bogdanci was originally planned to have a capacity of 50 MW. With 38.2 MW already built and commissioned in 2014, ESM has been working on completing the project in the previous years. The projected

40 Excluding VAT
41 Government of North Macedonia, Decision on the Total Installed Capacity of Preferential Electricity Producers, February 2019, Official Gazette of the Republic of North Macedonia, No. 29/19
42 Government of North Macedonia, Programme for Financial Support of Preferential Producers under Feed-in-Premium Scheme for 2019, February 2019, Official Gazette of the Republic of North Macedonia, No. 29/19.

construction period is 2.5 years and the planned commissioning date is in early 2022. The new 13.2 MW are expected to yield a yearly generation of 0.037 TWh.

(2) ESM have announced two large solar PV long-term projects to be built in multiple stages

I. Solar power plant Oslomej which is planned to have 100 MW capacity at its final stage. So far, there are actions taken for the first two stages.

- The first stage is 10 MW which should be completed within 8 months of commencing, setting the expected commissioning date in late 2020. The planned yearly generation is 0.015 TWh.
- The second stage of 20 MW is currently subject to a feasibility study. Its projected construction time is 1.5 years, with an expected commissioning date in 2021. The planned yearly generation is 0.030 TWh.

II. 120 MW solar power plant Bitola, near the largest thermal power plant in the country.

- A feasibility study is being conducted for the first stage of 20 MW. The projected construction period is 1.5 years, with expected commissioning date in 2022. The planned yearly generation is 0.030 TWh.

(3) The FIP scheme was implemented for the first time through a tender procedure in summer 2019. As outlined above, this scheme is expected to cover 200 MW of Solar PV plants, while there is no decision on the coverage of wind plants to this date. With this, North Macedonia has become the third contracting party to the EnC to launch a competitive process for supporting the investment in RES. The first tender awarded support in the form of fixed premium for a total of 35 MW of solar PV, which are to be built on state-owned land in two locations locations:

- 25 MW in Sveti Nikole split into 10 MW, 5 MW, two plants of 2 MW and six plants of 1 MW;
- 10 MW in Makedonski Brod.

Once the Government approves support for new wind power capacity, new investment projects are expected to emerge. The wind potential in North Macedonia is shown in Map 5.53.

Map 5.53 **North Macedonia wind speed map at 80 m**

Energy Efficiency and Cogeneration

National Targets

A new Energy Efficiency Law[34] was introduced in February 2020. The Law partially transposes the newest EU Energy Efficiency Directives. These Directives will be fully transposed by the adoption of the deriving secondary legislation. The Law stipulates the following basic obligations for the Governmental institutions:

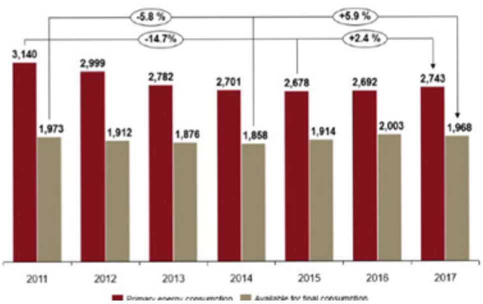
- To prepare and adopt a long-term Strategy to 2030 for Reconstruction of Housing, Public and Commercial Buildings, which is envisaged to provide an efficient, economically justifiable reduction of energy consumption by applying energy efficiency measures and at the same time reducing environmental pollution;
- To adopt a Decree on national energy efficiency goals and, accordingly, to develop three-year Action Plan for the implementation of EE measures;
- In order to ensure effective monitoring and verification of the implementation of EE measures, the Energy Agency shall manage, maintain and upgrade a web-based monitoring tool - Monitoring and Verification Platform (MVP);
- To adopt a Rulebook on MVP tool that will prescribe the procedures and technical parameters for the tool, as well as the rules for use and updating;

[34] Energy Efficiency Law, Official Gazette of the Republic of North Macedonia, No. 32/20, [Online]. Available only in local language: http://www.economy.gov.mk/doc/2766

- To regularly prepare and adopt three-year National Energy Efficiency Plan (NEEAP) and report on its execution to the relevant national and international institutions and bodies.

The last NEEAP covered the period until 2015 and its achievements were duly reported to the EnC Secretariat[44]. In general, primary energy consumption saw a decreasing trend, while final energy consumption remained stable. Between 2011 and 2017, the primary energy consumption decreased by 12.6% mainly due to a higher import of electricity and petroleum products, but partly due to implementation of energy efficiency measures and increased RES electricity production. This is shown in Figure 5.210.

Figure 5.210 **Primary energy and final energy consumption, 2011 – 2017 [ktoe]**



Source: Energy Development Strategy until 2040

In the last (3rd) NEEAP, it was estimated that achieved energy savings in 2015 amounted to 79.4 ktoe, or 4.85% of the reference consumption. That means that 99% of the planed energy savings in 2015 were achieved, as shown in Figure 5.210.

The Plan reinforced measures from its predecessor and introduced two new measures that together would contribute to cumulative energy savings of 148.7 ktoe in 2018.

This value represents a 9.09% reduction compared to the reference consumption. In addition, projections of primary energy consumption for 2020 were made taking 2016 as a base year and assuming and annual growth rate of 2.2%. As a result, the NEEAP estimated that primary energy consumption in North Macedonia will reach 3,014 ktoe in 2020, upholding the primary energy 'individual cap consumption' set for EnC countries, which is 3,270 ktoe. The 4th NEEAP for the period 2020-2023 is currently under preparation. It should set a new target against 2015 as a base year. It is expected that, after a public consultation, a draft plan will be submitted to the Government for adoption in April 2020 at the latest.

Furthermore, regarding the short deadlines on adoption of bylaws set by the then draft EE Law, a donor meeting was held with the aim to coordinate technical assistance in their preparation as early as November 2019. A consultancy of EBRD, under the 'Policy Window' of the Regional Energy Efficiency Program (REEP Plus), for the preparation of the Regulation setting out the binding energy efficiency scheme and the manner and measures for achieving the target referred to in Article 7 of the Energy Efficiency Directive has been agreed. The Government can choose measures to achieve savings of 0.7% per annum in final energy consumption compared to 2015.

Incentive-based Initiatives in the Building Sector

The currently conducted energy efficiency programme in the building sector is the National Programme for Energy Efficiency in Public Buildings in North Macedonia until 2020[45]. The 3rd NEEAP outlines 31 policies and measures, the majority of which have been implemented. The measures are divided in seven sectors: buildings, household, public, commercial, industry, energy and transport. Where the measures overlap multiple sectors, their overall savings are reported separately.

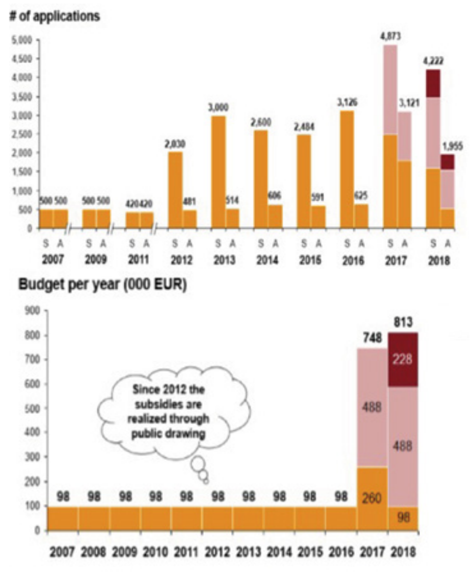
The implementation of measures on solar collectors, municipal street lighting, wider application of RES, and greater use of railway, all exceeded expectations. One third of the

44 https://www.energy-community.org/implementation/North_Macedonia/reporting.html
45 Draft National program for energy efficiency in public buildings in North Macedonia until 2020 (Phase I) is developed under the GEF Sustainable Energy Project and with technical assistance of, the World Bank Institute.

measures are partially implemented and only one (heat cost allocators) was not implemented at all.

The usage of RES and EE in households is promoted under the annual National Programme, implemented by the MoE. The following support schemes are stipulated in the programme: up to 30% reimbursement, with a cap of 300 €, of the costs for purchasing and installation of solar thermal collector system; up to 50% reimbursement, with a cap of 500 €, of the costs for purchasing and installation of PVC or aluminium windows; and up to 50% reimbursement, with a cap of 500 €, of the costs for purchasing a pellet stove. The eligible technologies are revised each year. The programme's popularity has been rising in previous years, as shown in Figure 5.211.

Figure 5.211 **Number of applicant and budget for promotion of RES and EE in households, 2007 - 2018**



Source: Energy Development Strategy until 2040

Furthermore, the Government adopted the Program for Promotion of Renewable Energy Sources and Promotion of Energy Efficiency in Households for 2019[46]. In 2019, 763 households were subsidized, out of a total of 1306 applicants who purchased and built solar collectors (about 163,000 €). Furthermore, 1503 households, out of a total of 2471 applicants, were subsidized for purchased and installed PVC or aluminium windows (about 646,000 €) and out of a total of 1863 applicants who purchased pellet stoves in their homes, 932 households were subsidized with about 50,000 € from the Budget.

EU Funded (or otherwise funded) Energy Efficiency Programmes in the Building Sector

The 3rd Annual Report Under the Energy Efficiency Directive[47] issued in June 2019 reports the following internationally funded projects, which are currently ongoing:

- A World Bank Public Sector Energy Efficiency Project through which, according the key findings and agreements reached during the mission in May 2019, the project will include a 25 million € IBRD loan to reduce energy consumption in the public sector and support the establishment and operationalization of a sustainable financing mechanism for the public sector (the proposed Energy Efficiency Found);
- An EBRD project through which five municipalities will conclude public private partnerships (PPPs) for providing public lighting energy services;
- A technical assistance form GIZ for operationalization of the Monitoring and Verification Platform (MVP) has been provided. The MVP platform will enable good communication and coordination between the national and local levels;
- A Residential Energy Efficiency project in the Western Balkans (WB) as part of the Economic Resilience Initiative-Infrastructure Technical Assistance (ERI-ITA) project, funded by the European Investment Bank (EIB);
- A Cool Heating project financed by Horizon 2020 - Framework programme for research and innovation 2014-2020. The project promotes an implementation of "small

46 Program for Promotion of Renewable Energy Sources and Promotion of Energy Efficiency in Households for 2019, Official Gazette No.15 / 2019
47 https://www.energy-community.org/implementation/North_Macedonia/reporting.html

modular renewable heating and cooling grids" for communities in SEE.

Cogeneration: Regulatory Framework, Installed Capacity

The currently operational cogeneration plants (CHPPs) in North Macedonia are CHPP TETO (227 MWe)[48], CHPP ESM Energetika (25 MWe) and CHPP Kogel Sever (30 MWe)[49].

The production of electricity by these three CHPPs is included within the information on electricity sector and specifically can be observed in Table 5.160. According to the new EE Law, the 5-year Programme for implementation of the Energy Development Strategy until 2040 (to be in place by mid-2020) should include the potential for application of highly efficient cogeneration and efficient district heating and cooling as well as cost-benefit analyses.

District Heating applications

The ERC Annual Report 2019[50] states that active district heating systems in the Republic of North Macedonia are present only at the territory of the City of Skopje, where there are three functioning systems. The largest district heating system is the one managed by BALKAN ENERGY GROUP JSC Skopje (BEG)[51], which in 2019 had about 53,281 consumers connected, with overall of engaged capacity of 475 MW, while 3,740 consumers were connected to the system of ESM JSC Skopje, Energetika Subsidiary with a total engaged power of 50 MW, and 496 consumers were connected to Skopje Sever JSC Skopje with an engaged power of 8 MW.

According to the Energy Law, for the systems with installed power of consumers of over 80 MW, licenses holders for production, distribution and supply of heat cannot be a single legal entity.

Therefore, BEG comprises three subsidiaries: BEG Heat Production, BEG Distribution of Heat and BEG Supply of Heat. In the systems operated by ESM JSC, Energetika Subsidiary and Skopje Sever, engaged power of the consumers is under 80 MW, and therefore all three licenses for production, distribution and supply are given to the single companies. They are all regulated businesses.

The BEG Heat Production capacities, connected to the grid of BEG Distribution of Heat, are:

- Thermal power plant Istok with installed thermal power of 279 MW, located in the east industrial zone of the city,
- Thermal power plant Zapad, with installed thermal power of 171 MW, located in the Taftalidge settlement and
- Thermal power plant 11-ti Oktomvri with installed thermal power of 28 MW, located in the Kisela Voda settlement.

The total installed thermal power of the heat plants (HPs) managed by BEG Heat Production is 478 MW, whereby natural gas is used to produce thermal energy. The CHPP TETO JSC Skopje is also connected to the distribution grid of BEG Distribution of Heat. It is with installed thermal power of 160 MW and is an only unregulated heat producer. ESM JSC Skopje, Energetika Subsidiary[52] owns the CHPP ESM Energetika and the CHPP Kogel Sever.

The total installed thermal power of ESM JSC Skopje, Energetika Subsidiary amounts 96 MW. ESM JSC Skopje also owns the majority part of the distribution grid managed and used by ESM JSC Skopje, Energetika Subsidiary.

Skopje Sever JSC Skopje produces thermal energy through two boilers of 23 MW each, i.e. has total installed thermal power of 46 MW. Heat production capacities of different producers, in 2019[53], are summarized in Table 5.160.

48 CHPP ESM Energetika untypically exists of two turbogenerators with installed electrical power of 12.5 MW each, built on the top of three existing thermal turbines with installed power of 32 MW each. The thermal units are mainly used for production of thermal energy. Source of information: ESM JSC Skopje

SKOPJE SEVER	Skopje Sever K2	Natural gas	HP	23

Source: ERC, Annual Report 2019

The overall heat production capacity is 793.88 MW, whereby, the engaged capacity of users is approximately of 510 MW. This situation provides connection opportunities for new heat consumers in the City of Skopje.

The heat production is dependable on the meteorology conditions, and usually the largest production is reached in the months of December and January. The overall heat production (kWh) in 2019[54] is presented in Table 5.161, below.

In line with the information of BEG Heat Distribution, the total length of its distribution network, including the length of connection points to facilities, as by the end of December 31, 2019, is 227 km. The length of BEG's distribution network and of the networks of the other two distributers, are given in Table 5.162. This Table also contains an information on average losses by distribution network.

Table 5.162 **Length of Distribution Networks and related Average Losses, in 2019**

Distributer	Length of Distribution Network (km)	Average Losses (%)
BEG Distribution	227	11.37
ESM Energetika	38	12.00
Skopje Sever	10	17.30
Total	275	

Source: ERC, Annual Report 2019

BEG Heat Supply is with the largest share of 88 % in the overall of the delivered quantities of heat. Next, is the system of AD ESM, Subsidiary Energetika with the share of 10 %, and the last is Skopje Sever with the share of 2 % in the overall delivered quantities of heat. Most of the consumers, about 77%, belong to the category of households.

The delivered quantities of heat in the past 10 years, by the three operational suppliers, are presented in the Figure 5.212.

Table 5.161 **Production of heat (kWh), by months and producers, in 2019**

January	67,455,499	69,823,099	10,887,000	2,244,000	150,409,598

Development and Investment Plans

In the forthcoming five-year period, BEG Heat Production plans to invest about 3 million €, in modernization and increased efficiency of its production facilities. It is expected that this investment will prolong the life cycle of their heat plants for the next 20 years[55].

Planned New Major Projects

The 3rd Annual Report Under the Energy Efficiency Directive[56] identifies the preparation of the following new EE projects in the Building Sector:

- An IPA2 Grant scheme for implementation of pilot measures for climate change and energy efficiency with emphasis on public buildings is under preparation, through which 4 million € will be provided from EU IPA funds;
- Negotiations are under way for launching a 25 million € through Loan Agreement for the Public Sector Energy Efficiency Project, which is part of the new four-year Strategy of EBRD – World Bank for partnership with our country for the period 2019-2023;
- EE Renovation of State Student Dormitories Project until 2024. The total investment value of the project amounts to approximately 25 million € (a loan from Germany, via KfW, in the amount of 20 million € and a grant from EU in the amount of 4.785 million €).

Furthermore, application of measures such as Energy Efficiency Binding Scheme, which prescribes rules and obligations for the distribution network operators and/or suppliers to achieve savings in the end-use energy consumption or to prove it by application of alternative measures, are prescribed by the new Law. Alternative measures include introduction of new pollution taxes, sale of energy-efficient products (other than those already in place), establishment of an EE Fund, voluntary agreements introducing high-efficiency technologies, campaigns, introduction of fees for purchasing inefficient products, i.e. use of inefficient services, renovation of municipal buildings and public enterprises, etc. The Law introduces an obligation for reconstruction of at least 1% of the total area of buildings used and/or owned by Government, annually.

Lastly, the EnC Secretariat places a focus on EE in buildings with its programme 2021 -2027[57]. Taking into account that the topic is expected to be prominent in the next EU financial framework 2021-2027, the EnC Coordination Group prepared this programme to tackle forthcoming EE issues. In order to do so, the programme sets out to assess and improve the national institutional, legal and regulatory frameworks governing the housing sector with an impact on energy investment. Its priorities include working with municipalities on heating and cooling, as well as nearly zero energy buildings, stricter EE requirements for appliances, and innovative funding programmes for residential buildings renovation

Energy Investment Outlook

The Energy Development Strategy sets out the following estimates and principles regarding investments between 2020 and 2040:

- A cost competitive transition would require a cumulative overnight capital investment ranging 9.4 – 17.5 billion € in the energy system of North Macedonia, depending on selected strategic scenario (Green, Moderate or Reference scenario).
- EE and RES investments are the primary focus of all scenarios. This allows the opportunity to benefit from increasing access to funding programmes that recognize the importance of energy transition projects - primarily EU funds as well as international financial institutions and donors.
- EE and RES projects, as well as the revitalization of TPP Bitola, will be also supported through the national budget.
- The pivotal year in the development is 2025, and decisions made in 2020 or 2021 at the latest will greatly influence the path through the energy transition. This requires immediate actions from the relevant energy stakeholders to start activities at all governance levels.

Since the Energy Development Strategy was adopted just recently (February 2020), an Action Plan for implementation of the Strategy, which will specify projects in different sectors, is to be prepared during 2020. Therefore, only information on short to mid-term investment plans of the regulated companies in the electricity and natural gas sectors of North Macedonia are available, either from the ERC's Annual Report 2018 or from sources within the companies themselves. That data is presented in the following sections. Collected information from different unstructured sources on potential mid-term investments in EE are presented along with the project descriptions in sections 4.6(c) and 4.6(e) of this text.

Electricity and Renewables

According to MEPSO's Ten-Year Network Development Plan until 2029[58], the major investments are presented in Table 5.163 and Table 5.164.

Table 5.163 **MEPSO Development Plan for the period 2019-2029**

No.	Projects	Budget Contract (MEUR)	Development plan (2019)	Development plan (2018)	Explanation about the costs difference or the time for commencement
Интерконективни врски					
1	400 kV interconnection line SS Bitola 2 – Macedonian/Albanian border	29.40	27.01	29.31	Costs structure is updated following the completed project and tender documentation and the procurement plans.
New transmission lines and transformer substations					
2	Transformer substation 400/110 kV SS Ohrid and new 400 kV OHL bay SS Bitola 2	14.00	13.72	17.61	Costs structure is updated following the completed project and tender documentation and the procurement plans.
3	Connection of 110 kV OHL HPP Vrutok - SS Skopje 1 in a transformer substation in the region of Polog	5.10	5.10	5.10	The completion time is prolonged for a year due to the specifics of the terrain, and the difficulties during tracing the access corridor.
4	Costruction of SS 400/110 kV Kumanovo (1 x 300 MVA)	15.00	15.00	8.60	The investment cost is updated in accordance with the actual prices of equipment, design and built of this type of facility.
Revitalization/ reconstruction of 110 kV lines					
5	Revitalizations of 110 kV lines	3.00	3.00	3.00	
6	Revitalization of OHL 2x110kV section Vapila - SS Ohrid 1	0.58	0.58	0.58	
7	Reconstruction of 110 kV OHLs section Vrutok - Tetovo	0.54	0.54	0.54	
8	Reconstruction of 110 kV OHL SS Shtip - TC Probishtip	2.45	0.42	1.92	The realization of the project has begun in 2018, the cost is updated according to the signed Contract, and in the development plan (2019) are given the funds for 2020.
9	Reconstruction of 110 kV OHL SS Bunardzik - SS Miladinovci	1.20	1.20	3.20	A new route is suggested as per rational execution; the newconnection point of the 110 kV OHL towards Miladinovci will be SS Bunardzik.
10	Reconstruction of 110 kV OHL SS Veles - SS Ovche Pole	1.81	1.16	3.19	In the development plan (2018) are used investment costs, while the contracts were signed at the end of 2019. The execution has stared in 2019. The costs and rate of progress were updated as per thesigned contracts and construction plans in coordination with the Bank. In the development plan (2019) the price was updated as per the contracts and the dynamic of costs given from 2020 onwards.
11	Reconstruction of 110 kV OHL SS Ovhe Pole - SS Shtip	1.41	1.01	2.88	
12	Reconstruction of 110 kV OHL SS Bitola 1 – SS Prilep	3.92	3.23	4.23	
13	Reconstruction of 110 kV OHL SS Skopje 4 –SS Petrovec - SS Veles	2.99	2.31	4.03	
14	Reconstruction of OHL 110 kV Gostivar (Bukovikj) - TPP Oslomej - Kichevo - Sopotnica - Bitola 1 length = 100 km AAAC)	3.10	3.10	3.10	The completion time is postponed for a year due to the optimization procedure during designing.
15	Reinforcement of the grid in the southeast region variant 1:Double-circuit 110 kV OHL to Strumica length = 57,5 km, AAAC-Z) or variant 2: 400/110 kV SS in Strumica (300 MVA)	7.1-25.0	7.10	5.24	The commencement of the project is planned 3 years earlier due to the increased interest for construction of RES in th SEE region. Unvestment costs were given about two variants, the costs wil be determined depending on the results from the Study (No.43).

Table 5.163

No.	Projects	Budget Contract (MEUR)	Development plan (2019)	Development plan (2018)	Explanation about the costs difference or the time for commencement
16	Reconstruction of OHL 110 kV Polog - HPP Vrutok - HPP Shpilje - HPP Globochica - Struga length = 100 km, AAAC)	7.95	1.00	9.06	The investment cost is updated following the actual prices of equipment, design and built of this type of facility, and in the plan ae given the funds for 2027-2029.
Revitalization /Reconstruction of transformer substations					
17	Revitalization of transformer substations	14.20	14.20	14.20	
Reconstruction/upgrade of swichyard Kratovo					
18	Construction of 110 kV transmission bays, complete Reconstruction and digitalization of the switchyard	0.70	0.70		New project for upgrade of switchyard Kratovo.
Ревитализација на ТС Скопје 4					
19	High-voltage equipment (breakers, disconnectors, *measurement transformers)*, control panels	4.80	2.34	4.36	
20	Power transformer (5-СК4-1ТА)	2.50	2.50	2.50	
Revitalization of SS Dubrovo					
21	High-voltage equipment (breakers,disconnectors, measurement transformers), auxiliary equipment (relay protection, SCADA, measurement transformers), rectifiers of 220 DC systems)	4.62	0.24	1.41	
22	Power transformer (3-ДУБ-1ТА)	2.50	2.50	2.50	
Revitalization of SS Bitola 2					
23	High-voltage equipment (*110 kV breakers)*, secondary equipment	1.00	0.42	0.93	
24	Power transformer	2.40	2.40	2.40	
Revitalization of SS Valandovo					The costs and the rate of progress are updated according to the signed contracts and current plans for execution; the dynamic of costs are given from 2020 onwards.
25	BH equipment (measurement transformers, breakers and disconnector)	0.77	0.18	0.70	
Revitalization of SS in TPP Oslomej					
26	BH equipment (diconnectors breakers measurement transformers)	0.63	0.21	0.57	
Revitalization of SS in HPP Tikvesh, HPP Vrutok, HPP Globochica and HPP Shpilje					
27	Secondary equipment (relay protection)	0.63	0.19	0.56	
Revitalization of SS Prilep 1					
28	High-voltage equipment (breakers,disconnectors, measurement transformers), auxiliary equipment (relay protection, SCADA, measurement transformers), исправувачи на 220 DC систем)	1.12	0.26	1.01	
Revitalization of SS Veles and SS Kavadarci 1					
29	Adaptation. Supply and installation of the primary equipment, installation of SACS, Protection and DC supply	0.54	0.54	0.52	
Revitalization of SS Kochani					
30	Shunt compenzation in 110 kV SS Kochani (25 Mvar)	0.75	0.75	0.75	
Modernization of the transmission system					
31	Telecommunication equipment and remote monitoring of the transformer substations	5.00	5.00	4.79	The cost and dynamic are updated following the plans for supply and installation.
32	Underground facility for optical connection	0.20	0.20	0.20	The commencement period is postponed for a year due to terrain problems.
33	Balkan Digital Highway	5.80	5.80		*Студија за развој на оптичка и телекомуникациска мрежа и проценка на вкупни трошоци за интегрирање во национален широко појасен план* и *Проектот за ревитализација на телекомуникациска мрежа* се надградени во регионален проект за креирање „дигитален автопат", финансиран преку WBIF и координиран од Светска Банка.
34	Wide Area Monitoring System-WAMS	0.15	0.15	0.15	Цената и динамиката е ажурирана според плановите за набавка и инсталација.
35	DLR - Dynamic Line Rating	1.23	1.23	0.60	New smart grid project as part of the Implementation of new technologies in the transmission grid; the project is needed for optimal utilization of the existing capacity of the transmission lines
36	Special software and hardware package for maintenance of the transmission grid	0.27	0.27	0.20	The cost and dynamic are updated following the plans for supply and installation.
Research on Power Transmission System					
37	CROSSBOW	0.18	0.10	0.15	The costs are updated in in accordance to the planned undertakings in 2020 and 2021.
38	TRINITY	0.80	0.08	0.08	New scientific and research project financed by Horizon2020.
39	Study on Optimal Utilization of the Double-circuit Busbars in the Substations	0.02	0.02	0.02	The commencement period is shortened as to faster concept implementaton.
40	Transmission Network Development Study	0.08	0.08		Preparation of a new Transmission Grid Development Study based on the new Energy Development Strategy.
41	Action Plan for Power Grid Strengthening to Support Renewable Eenergy Projects in North Macedonia	0.08	0.08		New study financed by EBRD because of the actuality of the RES integration.
42	Study on Voltage Profile Improvement of the Smart Grid	0.60	0.60	0.60	The Study is expected to be completed at the beginning of 2020.
43	Strengthening the Transmission Network in the Southeast Region of North Macedonia	0.25	0.25	0.03	The Study will be carried out as part of the WBIF Grant for technical support and and will have enlarged scope of work: more variants, project and tender documentation for optimal variant.
Cancelled/posteponed projects and undertakings in the new development plan					
	Reconstruction/revitalization of 110 kV OHL SS Kavadarci -HPP Tikvesh				By the Strategy for reconstruction/revitalization of the transmission grid, these reconstructions have a lower priority for realization and are excluded from the 10-year period.
	Reconstruction/revitalization of 110 kV OHL SS Gj. Petrov –SS Skopje1				
	Study for tower testing station				The project is delayed.
	Study for Procedures and Technologies for Organization, Operation and Planning in MEPSO				The study is delayed.
	Investigation of Potential Increase of the Bidirectional Transfer Capacity in the MK-GR Border				The results of the new calculations for system requirements by ENTSO-E TYNDP2020 are expected.

Natural gas

Data on planed mid-term investments, which are presented in section 4,2(g), are gathered from the latest ERC's report and presented in Table 5.167 and Table 5.168.

Table 5.167 **Development and investment plan of natural gas TSO, GA-MA, in thousand €**

Investments	2019	2020	2021	2022	2023	Total
x1000 €	4,472	3,203	2,585	1,724	2,130	14,114

Table 5.168 **Development and investment plan of DTIDZ for TIDZ Skopje (thousand €)**

Investments	2019	2020	2021	2022	2023	Total
Equipment supply	33	65	65	65	65	293
Constructing pipe for connecting new users in "TIDZ Skopje1"	163	/	/	/	/	163
Constructing pipe for connecting new users in "TIDZ Skopje2"	407	/	/	/	/	407
Total	602	65	65	65	65	862

These correspond to an ambitious country-wide gasification plan. DTIDZ plans to provide the necessary investment funds from the Budget of the Republic of North Macedonia, as well as from the funds collected from the self-funding activities of the Directorate. Projects related to phase 1 are expected to be completed by 2020, phase 2 by 2022 and phase 3 after 2022.

ROMANIA

Romania

Economic and Political Background

Romania's GDP was USD 250 billion in 2020, while the GDP per capita was 12,900 USD, according to the World Bank. For the first time ever, the World Bank classified Romania as a high-income country, based on 2019 data (per capita income of $12,630) - an important development for accession negotiations to the Organisation for Economic Cooperation and Development (OECD)[1].

The IMF's database of October 2020[2] showed that Romania's economy contracted 1.4% in annual terms in the final quarter of last year, above the preliminary estimate of a 1.5% decline and softening from the 5.6% drop tallied in the third quarter. All in all, the economy shrank 4.8% in 2020, swinging from 2019's 4.1% expansion and logging the worst reading in a decade. A second release showed that Romania's economy contracted 1.4% in annual terms in the final quarter of last year, above the preliminary estimate of a 1.5% decline and softening from the 5.6% drop tallied in the third quarter. All in all, the economy shrank 4.8% in 2020, swinging from 2019's 4.1% expansion and logging the worst reading in a decade.

Private consumption fell at a sharper rate of 5.5% year-on-year in Q4 2020, deteriorating from the 4.3% contraction in the previous quarter. Moreover, government spending dropped for the first time since Q2 2018, declining 1.2% (Q3: +3.5% y-o-y). However, fixed investment grew at a stronger rate of 6.5% in Q4 compared to the 2.7% increase recorded in the prior quarter. On the external front, exports of goods and services contracted at a slower pace of 3.1% year-on-year in the fourth quarter (Q3: -5.2% y-o-y). Meanwhile, imports of goods and services flatlined at the tail end of the year (Q3: -4.3% y-o-y).

On a seasonally-adjusted quarter-on-quarter basis, economic growth moderated to 4.8% in Q4 from 5.6% in the previous quarter. Looking ahead, the Romanian economy is expected to bounce back from 2020's pandemic-induced plunge on the back of reviving domestic and foreign demand. Moreover, incoming EU funds and an accommodative monetary policy should further support the recovery. However, much depends on the progress of vaccination efforts at home and in key trading partners, with new strains of Covid-19 and the possible prolongation of restrictions clouding the outlook. IMF estimates that Romania's GDP will expand by 4.6% in 2021, significantly higher than -4.8% in 2020.

The justice laws in Romania draw again tensions among politicians. The Chamber of Deputies finally voted for the abolishment of the Section for the Investigation of Crimes in Justice, a controversial prosecution office created for the investigation of corruption cases among magistrates. However, the bill adopted by the deputies also includes an amendment stipulating that magistrates can be prosecuted only with the approval of the magistrates' body, which raised the fear that a super-immunity of magistrates could be enhanced in this way. While the governing coalition agrees to the actual format of the law, the major opposition party supports the preservation of the institution. Recent tensions inside the coalition parties on new amendments to the justice laws point to further discussions on this topic.

A note on Unemployment

When it comes to **unemployment**, the official statistic for Romania has to be taken with a grain of salt. While low (5%) compared to the EU average (7%) – data for 2020[3], it does not reflect reality. Structurally, Romania has had, for a long time, a significant number of people active in the underground economy (an estimated 1/5 of the labor force).In addition, an estimated 3 million Romanians reside and work abroad, most of them in the EU.

[1] https://www.worldbank.org/en/country/romania/overview

[2] It should be noted that most of the available analyses (feeding the chapter "Energy and Emissions Projections for SE Europe") do not include the effect of the COVID-19 pandemic and its possible long-term effects to the macroeconomic development and the energy systems of the countries in the region.

Of those who stayed in Romania, people who have been out of a job for many years have stopped looking altogether relying on informal, seasonal or household work (especially in rural areas) in order to get by, which is why a significant number of unemployed (at least 10%) are completely unaccounted for in the official statistics (since they are neither "employed" nor "unemployed" nor "looking for a job"). The **real unemployment figure should be at least 15%**. Romania has a population of 19 million, of which 7 million are economically inactive (children, pensioners, people with disabilities, housewives) which leaves a labor force of 12 million. According to the ILO, total labour force participation rate in Romania is just 55% (2018 data) which translates into 6.6 million employed people, implying that the remaining 45% (5.4 million) are unemployed. Of the 45% unemployed, only 5% (500,000 persons) are counted in the official unemployment rate. Another 20% (2.5 million) work in the underground economy, while the remaining 20% of the unaccounted unemployed is made up of structurally unemployed or the "extremely poor" (10%, 1.25 million) and seasonal workers that go abroad for short periods of time (10%, 1.25 million).

Energy Policy

National Energy Policy

The primary objective of Romania's energy policy is to ensure energy supply from its own internal sources. According to the final Integrated National Energy and Climate Plan (INECP) submitted by Romania in April 2020, energy policy is structured around 5 dimensions: decarbonization, energy efficiency, energy security, internal energy market, and research, innovation and competitiveness.

In some ways Romania's national energy strategy can be described as a white elephant. A document originally written in 2016, and subsequently re-written over 2017-2018 (but never adopted), it has little insight to offer, since much has changed in the past 2-3 years. Assumptions used 5 years ago are no longer valid. A more recent document, the INECP, also lacks focus and is mostly a wishlist – a collection of plans of state-owned companies combined with a regurgitation of EU legislation. Estimates made in Romania's INECP are already outdated, since they are based on assumptions made in 2016 by the PRIMES scenario. For instance, annual economic growth was projected to be 2.7% during 2020-2025 and 2% during 2025-2030 (INECP, pg. 141) – a projection that is already outdated.

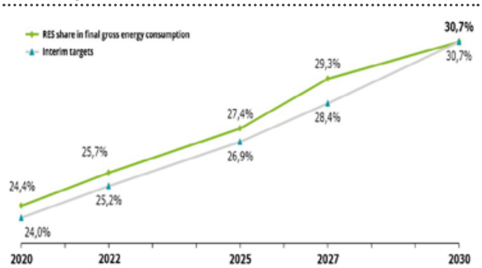
During 2017-2019, the country struggled to move towards decarbonization (decision makers fought to keep the coal-fired generation

[3] https://ec.europa.eu/eurostat/documents/portlet_file_entry/2995521/3-04032021-AP-EN.pdf/cb6e5dd6-56c2-2196-16b7-baf811b84a4f

until the very last moment, some still do). Only reluctantly Romania agreed to up the target for renewable energy sources for 2030 - initially set at 27.9%, it was increased to 30.7%, which is still below the 34% recommended by the European Commission. Under pressure from the European Union, Romania grudgingly agreed to mitigate.

In Romania, GHG mitigation during the next decade will mean:
- radical overhaul of the main coal-based electricity producer (Complexul Energetic Oltenia), which is to switch from coal to natural gas and renewables;
- extending the operating period of existing nuclear units + building new nuclear capacities;
- adding new RES capacities and promoting the use of hydrogen;
- developing/upgrading the existing infrastructure of electricity and natural gas networks;
- developing storage capacities.

Figure 5.216 **Projected RES share in final energy consumption (2021-2030), in %**



Source: INECP 2020

This target for RES will most likely be exceeded, due to the availability of extra funding for green projects, especially through the Resilience and Recovery Facility in the next few years and through the Modernization Fund (mechanism 10d), on top of the traditional EU funding channeled through the 7-year Multiannual Financing Framework (MFF). Hence, the key issue becomes Romania's ability to attract all this available money. Everything hinges on its ability to understand what energy transition is and what it is not. For instance, note analysts, energy transition does not mean granting a state loan of 250 €million to the main coal-fired electricity producer. On the other hand, it means having mature green projects, and avoiding wasting any more time and money with loss making enterprises by trying to keep them alive. There is a general consensus today in Romania that the Green Deal has not been sufficiently internalized and well understood, and the necessary strategic documents have not been updated to reflect the new imperatives.

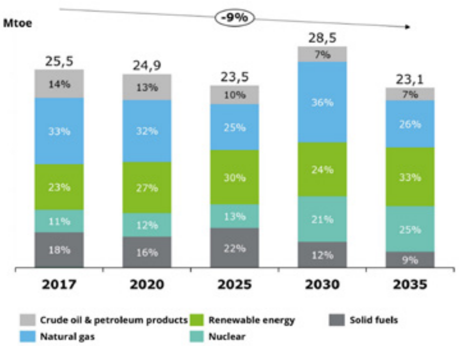
Governmental institutions
- **Parliament, the Committee for Industries and Services**, is responsible for drafting the primary legislation in the energy sector.
- **Energy Ministry** coordinates the state-owned companies in the energy field (with the exception of the TSO in electricity and natural gas).
- **General Government Secretariat/ Prime Minister's Office** has kept oversight of two key energy companies - the electricity and natural gas TSOs (Transelectrica and Transgaz).
- **National Agency of Mineral Resources (ANRM)** organizes tenders and concludes contracts for mineral resource exploration and production, including oil and gas. Extremely weak institution, subordinated to the Prime Minister's office.
- **Romanian National Regulatory Agency (ANRE)**, independent and autonomous body, under the supervision of Romanian Parliament, which is in charge of drafting the secondary legislation for electricity, natural gas and heat.
- **OPCOM** – state-owned market operator. Manages the platform for trading of electricity, natural gas, and issues Green Certificates. It is not the only market operator, since there is also the Romanian Commodity Exchange (Bursa Romana de Marfuri, BRM).
- **Ministry of Environment** issues environmental permits.
- **Environment Guard** has a weak law enforcement capacity.
- **Transelectrica** is the electricity TSO. Authorizes connections to the grid, is in charge of electricity transmission activity, grid maintenance and carrying new investments, issues Green Certificates (GCs) and administers the cogeneration bonus.
- **Transgaz** is the gas TSO.

Energy Demand and Supply

National energy demand and supply

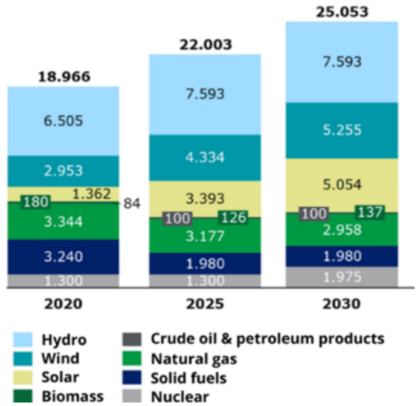
As shown in Figure 5.217, demand is projected to decrease after 2030, but supply as shown in Figure 5.219 is projected to grow by 2030.

Figure 5.217 **Primary energy production, by energy source (2017-2035 forecast, in Mtoe)**



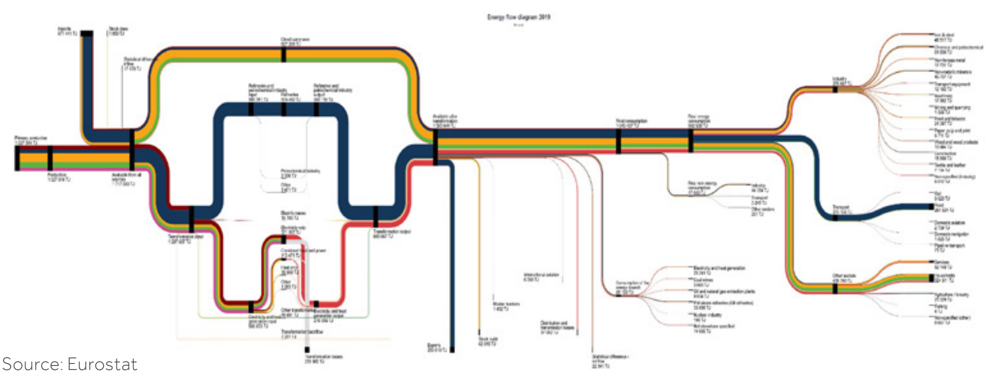
Source: INECP 2020

Figure 5.219 **Expected development of net installed capacity by source (in MW)**



Source: INECP 2020

Figure 5.218 **Romania energy balance for 2019 in Terajoule (TJ)**

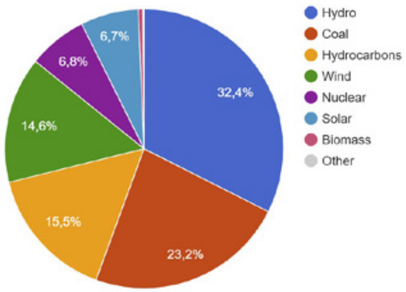


Source: Eurostat

Electricity mix

Presently, Romania has a well-balanced electricity mix, with the highest installed capacity in hydro (6,704 MW equivalent to 32.4% of the total installed capacity), followed by coal (4,787 MW, 23.2% of total installed capacity), and by natural gas (3,211 MW, 15.5% of total capacity). In terms of installed capacity, wind comes 4th (with 3,024 MW, and a 14.6% share), and nuclear 5th (1,413 MW, 6.8%), and solar is 6th (1,392 MW, 6.7%). See the figure below.

Figure 5.220 **Installed electricity capacity per source (in % share)**

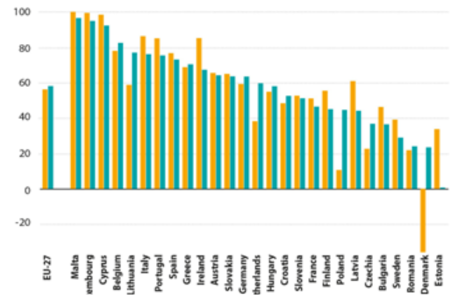


Source: ANRE, March 2020

Degree of energy dependence

Romania constantly ranks as the third (and second, after Brexit) least energy dependent country in the EU. While the EU-27 average rate of energy dependency was 58% in 2018, Romania's dependency rate was a little over 20%. Along with Denmark and Estonia, Romania was among the top 3 countries with the lowest energy dependence in 2018. This is due to rich domestic resources such as hydro, coal, natural gas, nuclear and renewables. This is, to a large extent a legacy of the communist regime, which pursued a policy of self-reliance and diversification. Contemporary Romania has further built on this favorable inherited mix, with efforts focusing on developing new RES capacity (mostly other than hydro) and on shrinking the share of coal in the energy mix. However, this good fortune also led to complacency with regard to developing new hydrocarbon resources, as evident by the 8-year delay in the development of the Black Sea natural gas resources discovered in 2012. The decrease of coal's share in the energy mix is still unfolding, but it is mostly the result of the pressure from Brussels and of the EU energy and climate policy, not an autonomous or conscientious decision made by the Romanian government.

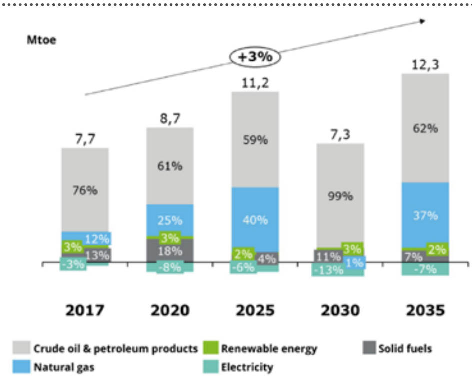
Figure 5.221 **Energy dependency rate (%), 2018 vs. 2000**



Source: Eurostat

Despite Romania's favorable current situation, overall energy dependence is expected to increase by 2025, then to drop in 2030 (due to an increase in domestic gas production) and increase once again by 2035.

Figure 5.222 **Net imports by energy source (2017-2035 forecast)**



Source: Romania's INECP, 2020

The energy import forecast for 2017-2035, as shown in Fig. 8, suggests that Romania will remain an electricity exporter until 2035. This, however, is already no longer the case, as in 2019 Romania became a net electricity importer. Whether Romania will be an importer or exporter of electricity will depend on how fast new generation assets will come online.

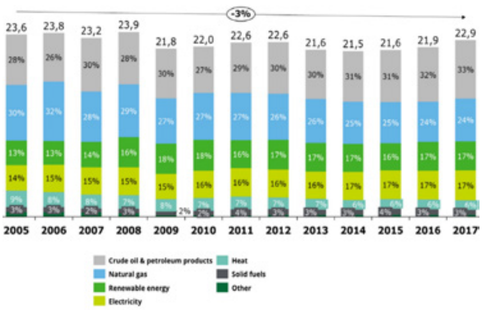
Most likely, until 2025 Romania will be a net electricity importer, and will revert to electricity exporter status only after the additional generation capacity is put in place (see plans for new power plants detailed in the "Cogeneration" and "Energy investment outlook" sections).

The Energy Market

Oil and Petroleum Products

(a) Oil supply and demand

Figure 5.223 **Structure of final energy consumption by energy source (2005-2017)**



Source: Romania's INECP, 2020

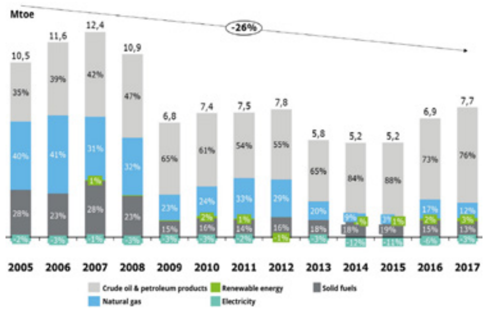
Between 2005 and 2017, oil and petroleum products accounted for 30% (on average) of final energy consumption – the largest share of all energy sources, as shown in Fig. 9 on the structure of final energy consumption by energy source.

While overall energy imports decreased by 26% from 2005 until 2017, the share of crude and petroleum products in energy imports doubled during this period (from 35% in 2005 to 76% in 2017). See Fig. 5,224 on net energy imports. At the same time, as Romania exhausts its domestic oil reserves without improving its reserve replacement, the import of crude and petroleum products is likely to go up. The main crude producer in Romania remains OMV Petrom. The company is also the main user of the oil pipeline system (OMV Petrom is Conpet's largest client, accounting for 80% of its revenues). Key Romanian refineries are Petromidia (5 Mt/year refining capacity), Petrobrazi (4.5 Mt/y) and Petrotel - Lukoil (2.7 Mt/y).

(b) Oil imports/dependence

The quantity of energy imports fell in 2009 and never recovered to its pre-2008 level. Net energy imports dropped from 10.9 Mtoe (2008) to 6.8 Mtoe (2009) and hovered around 7 Mtoe during the next decade. Crude and petroleum products (which used to account for 35% of imports in 2005) represented 76% of total energy imports in 2017. On the other hand, the share of natural gas and solid fuels has dropped significantly since its peak years (2005-2008), a trend that is persisting, as shown in Figure 5.224.

Figure 5.224 **Net energy imports, by energy source (2005-2017)**

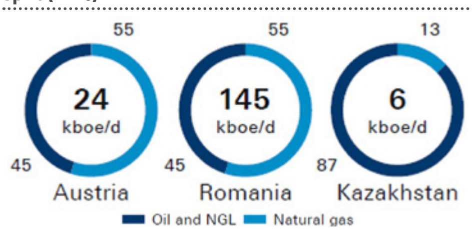


Source: Romania's INECP, 2020

(c) Upstream sector - domestic production and exploration

OMV Petrom remains the largest oil producer in Romania. At the end of 2019, the company operated 193 onshore and offshore production licenses and was active in 10 exploration licenses. Total hydrocarbon production was 145 kboe/d, of which 55% natural gas and 45% crude. Romania remains the most important country in OMV's production portfolio. By comparison, its assets in Austria produce just 24 kboe/d and those in Kazakhstan produce just 6 kboe/d.

Figure 5.225 **OMV production in CEE, plus oil and gas split (in %)**



Source: OMV Factbook 2019

Figure 5.226 **Daily production of OMV in CEE (in kboe/d)**

Although OMV has expanded and now has a global footprint, Romania remains the top hydrocarbon producer (145 kboe/d) in its upstream portfolio, followed by Russia (100 kboe/d), and Norway (87 kboe/d).

Table 5.169 **OMV global hydrocarbon production in 2019, by country and by region (2015-2019)**

Source: Romania's INECP, 2020

Table 5.169 underscores the central role that Romania continues to play in OMV's upstream portfolio. Despite OMV's diversification and market entry in other geographical areas (Middle East, Africa, Asia Pacific, Kazakhstan, Russia), so far none of these new assets have outstripped the hydrocarbon production OMV has in Romania. However, there has been a visible decline between 2015-2019 in OMV's Romanian hydrocarbon production: from 170 kboe/d in 2015 to 145 kboe/d in 2019.

As Table 5.170 shows, Romania holds a prominent place among OMV's major licenses in various countries.

Table 5.170 **OMV's major licenses in Romania, Austria, Kazakhstan, Norway and Russia**

Note: Romania's and Austria's licenses are clustered into asset units due to their large number (more than 190 in Romania, more than 150 in Austria).

For the exact location of the 12 cluster assets in Romania, please see map on next page.

5

Map 5.55 **OMV Petrom's oil & gas assets (as of December 2019)**

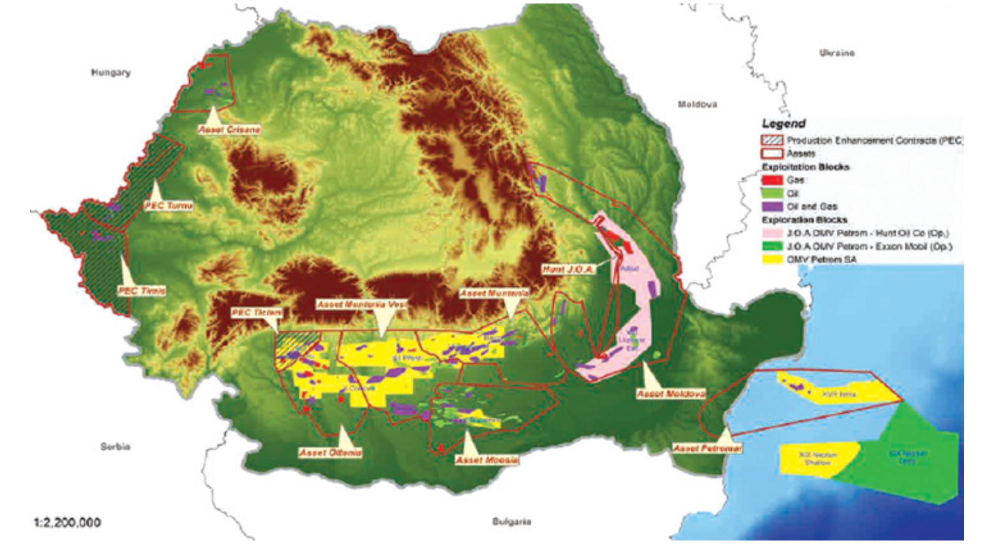

Table 5.171 **OMV production in 2019 in Romania and Kazakhstan, oil and natural gas**

	Oil and NGL		Natural gas		Total
	mn t	mn bbl	bcm	mn boe	mn boe
Romania	3.34	24.06	4.42	28.92	52.97
Kazakhstan	0.27	2.07	0.05	0.30	2.37
OMV Petrom Group	**3.61**	**26.12**	**4.47**	**29.22**	**55.35**

In Romania, 26% of Petrom's total domestic production is based on EOR techniques. Heavy oil accounts for 36% of the total crude and NGL production.

Since 2010, OMV Petrom concluded partnerships with international companies, such as PetroSantander and Expert Petroleum, for production enhancement. The production enhancement contracts (PECs) cover 22 mature fields in total, which are clustered in 3 groups: PEC Timis, PEC Turnu, PEC Țicleni. Under this type of contract, the contractors finance and take over operations, but OMV remains the sole titleholder of the concession and owner of the hydrocarbon production and assets. Total production under PECs was 7.3 kboe/d in 2019, of which 3.9 kboe/d from PEC Țicleni, 1.2 kboe/d from PEC Turnu and 2.2 kboe/d from PEC Timis.

Under the Joint Operations Agreement with Hunt Oil (50% OMV Petrom, 50% Hunt Oil as operator) production was 1.4 kboe/d (OMV Petrom share). Total production under PECs and the Joint Operations Agreement with Hunt Oil was 8.7 kboe/d, representing juts 6% of OMV Petrom's domestic production in Romania.

(d) Downstream and midstream sectors infrastructure (Refineries, Pipelines, Storage, Terminal and Domestic Oil Market)

The main players in the downstream sector are OMV Petrom (the main player on the Romanian fuels market with a 32% market share also in the region), Rompetrol (8% market share in Romania) and Lukoil.

OMV Petrom operates one refinery in Romania - Petrobrazi.

Petrobrazi refinery has a refining capacity of 4.5 million tons per year and achieved a utilization rate of 97% in 2019 (up from 85% in 2018). Petrobrazi can process OMV Petrom's entire Romanian equity crude oil. The refinery also has a hydrogen plant on its premises.

Its latest upgrade was the Polyfuel plant, with an investment worth 65 million EUR. The plant allows 90,000 tons of high-octane gasoline and diesel to be obtained through reconversion of LPG and low-grade light gasoline. The unit is "the third of its kind worldwide and the first to convert low-grade light gasoline as well, not just LPG" according to the company annual report for 2019.

OMV Petrom has a network of 793 filling stations in the Black Sea region, most of which (556 stations) are located in Romania. It has 94 filling stations in Bulgaria and 81 in Moldova.

Table 5.172 **Number of filling sations per country at the end of period**

Romania	556
Moldova	84
Bulgaria	94
Serbia	62
Total	**793**

In terms of sales, OMV sold 5.5 million tons of refined products in 2019, of which 2.8 million tons were retail sales. Retail sales in Romania were 2.4 million tons in 2019. The company boasts to have achieved a record throughput in Romania: 5 million liters per filling station in 2019.

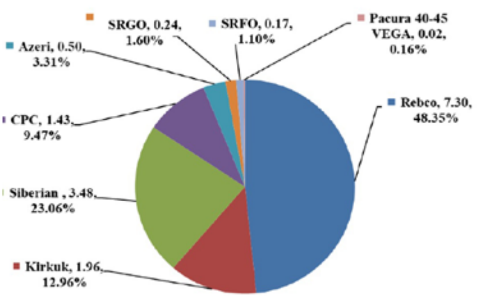
Rompetrol operates 2 refineries in Romania: **Petromidia Refinery** (in Constanta) and **Vega** refinery (in Ploiesti) and a **petrochemical plant** (in Navodari, Constanta).

Petromidia refinery is the largest in Romania and one of the most modern in the Black Sea region with a Nelson complexity index of 11.4. Ranked 9th among 250 refineries in Europe and Africa by Wood MacKenzie in 2018. The refinery has the highest white product output in the region (86.2%) and a utilization rate of 90% (higher than the average European utilization rate of 83%).

In addition, it has the highest in the region capability to extract sulphur from oil, obtaining exclusively Euro 5 fuels. KazMunayGaz (KMG) has invested 1.6 billion USD since it took over the company, of which 1 billion USD was invested in Petromidia. The largest project was the upgrade and increase of its capacity from 3.5 Mt/year to 5 Mt/year, a project worth 450 million USD.

As shown in Fig. 5.228, the total feedstock processed in 2019 was 6.33 million tons while gasoline production was 1.37 million tons, jet group production was 406 ktons, diesel production 2.93 million tons (highest ever).

Figure 5.227 **Petromidia refinery: feedstock structure in 2019 (in 000 tons/day, and % it represents)**



The yield for diesel was 48.5% and for fuels (gas, diesel, Jet, automotive LPG fuel) is 75.4%. The finished products are sold in the domestic market as well as in the international market.

The main export markets, by petroleum product, are:

- gasoline: Greece, Georgia, Lebanon, Bulgaria, Moldova, Turkey;
- diesel: Greece, Bulgaria, Moldova, Turkey, Georgia;
- jet fuel: Moldova, Georgia, Bulgaria, Albania;
- petcoke: Turkey, Moldova, Ukraine, Serbia, Hungary;
- sulphur: Egypt, Ukraine.

Table 5.173 **Petromidia refinery: structure of deliveries in 2019**

OIL PRODUCTS	TOTAL DELIVERIES	DELIVERIES					
		DOMESTIC *		EXPORT		TRANSFER	
	[tons]	[tons]	[%]	[tons]	[%]	[tons]	[%]

TOTAL	**5,955,930**	**3,072,857**	**51.59**	**2,334,773**	**39.20**	**548,362**	**9.21**

** The quantities delivered for domestic consumption include the petroleum products marketed on the domestic market. The deliveries to Vega and Petrochemical are included under the heading "transfer"*

Most of the gasoline produced at Petromidia is exported (1 million tons or 74%) and only 357,000 tons (26%) is supplied to the domestic market. In contrast, most of the diesel fuel (1.9 million tons, or 65%) and most of the LPG (178, 678 tons or 68%) is sold in the domestic market. Overall 52% of the finished products are sold in the domestic market, and 40% are exported. Motor fuels (gasoline, diesel, LPG) account for 80% of total finished products sales.

Vega refinery is the oldest processing unit in Romania (115 years). It is the only domestic producer of bitumen and hexane. Its total feedstock in 2019 was 436 kt while hexane production was 92 kt and bitumen production was 120 kt. Vega works in perfect synergy with the Petromidia refinery.

Table 5.174 **Vega refinery: structure of petroleum products deliveries in 2019**

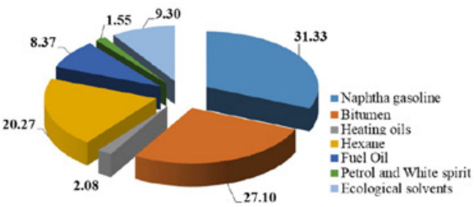
Group of products	TOTAL DELIVERIES 2019		DOMESTIC		EXPORT	
	[tons]	% of total sales	[tons]	%	[tons]	%
Naphtha gasoline	138,953	31.33	48,823	35.14	90,130	64.86
Bitumen	120,199	27.10	119,219	99.18	980	0.82
Heating fuels	9,247	2.08	9,247	100.00	-	-
Hexane	89,889	20.27	3,110	3.46	86,779	96.54
Heavy fuel oil	37,120	8.37	36,833	99.23	287	0.77
Petroleum and White spirit	6,890	1.55	4,926	71.50	1,964	28.50
Ecologic solvents	41,228	9.30	679	1.65	40,549	98.35
Total	**443,526**	**100.00**	**222,837**	**50.24**	**220,689**	**49.76**

Vega focuses on the production of solvents (SE 30/60, n-Hexane, white spirit)), naphta, heating fuels, normal road bitumen and modified bitumen (Fig. 5.229). Two thirds of the naphta gasoline produced at Vega is exported. The entire bitumen production (119,219 tons or 99%) and 100% of the heating fuels (9,247 tons) is used in the domestic market, as is 99% of the heavy fuel oil. On the other hand, ecological solvents go mainly to export (98%).

The main export markets for petroleum products produced at Vega are:

- naphta: Hungary, Slovakia, Czech Republic, Poland, Spain;
- hexane: India, Turkey, Ukraine, Bulgaria, Russia;
- ecological solvents: Germany, Cyprus, Spain, Ukraine, Hungary, Moldova;
- white spirit: Bulgaria, Moldova;
- fuel oil: Bulgaria;
- bitumen: Bulgaria.

Figure 5.228 **Structure of Vega sales, by product (in %)**



Navodari petrochemical plant is the only producer of polypropylene (PP) and polyethylene (LDPE, HDPE) in Romania.

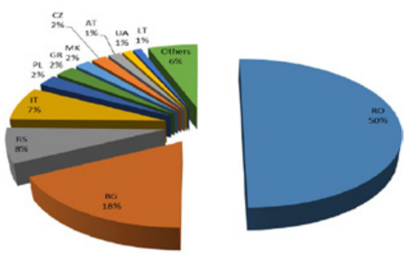
Table 5.175 **Navodari petrochemical plant: structure of polymers deliveries in 2019**

		DELIVERIES			
PRODUCTS	TOTAL DELIVERIES	DOMESTIC		EXPORT	
	[tons]	[tons]	[%]	[tones]	[%]
PP	91,771	40,112	44%	51,659	56%
LDPE	38,121	25,053	66%	13,069	34%
HDPE	3,316	1,101	33%	2,215	67%

Note: PP = polypropylene; LDPE = low density polyethylene; HDPE = high density polyethylene.

In addition to its own products, the petrochemical plant also sells products of high demand in the domestic market (which are not produced there) such as HDPE variants, LLDPE, PVC, or PET. The main markets for polymers (PP, LDPE, HDPE, PET, PVC) are Romania (50%), Bulgaria (18%, Serbia (8%) and Italy (7%), as shown in Figure 5.229.

Figure 5.229 **Polymer Sales by Destination 2019**



Domestic fuel sales:

Rompetrol Downstream distribution segment has 964 points of sale (December 2019) which include its own network of stations plus partner stations and mobile stations. Rompetrol Downstream sold 2.11 million tons of fuel on the Romanian market in 2019, an increase compared to 2018, largely due to a boost in diesel sales. Diesel has the highest share (84%) of the total motor fuels sold by Rompetrol nationwide.

Lukoil

In Europe, the company fully owns 3 refineries (in Romania, Bulgaria and Italy) and holds a 45% share of a refinery in Netherlands as shown in Table 5.176.

Table 5.176 **Lukoil owned refineries in Europe in 2019**

Country	Refinery	Built	Acquired	Refining capacity	Nelson index
Romania	Petrotel-Lukoil	1904	1998	2.7 million tons	10
Bulgaria	Burgas	1964; 1975	1999	7 million tons	13
Italy	Isab	1964	2008 (49%); 2011 (60%); 2012 (80%); 2013 (100%)	14 million tons	10.6
Netherlands	Zeeland (ex-TRN)	1973	2009	3.6 million tons	8.4

Source: compiled by author

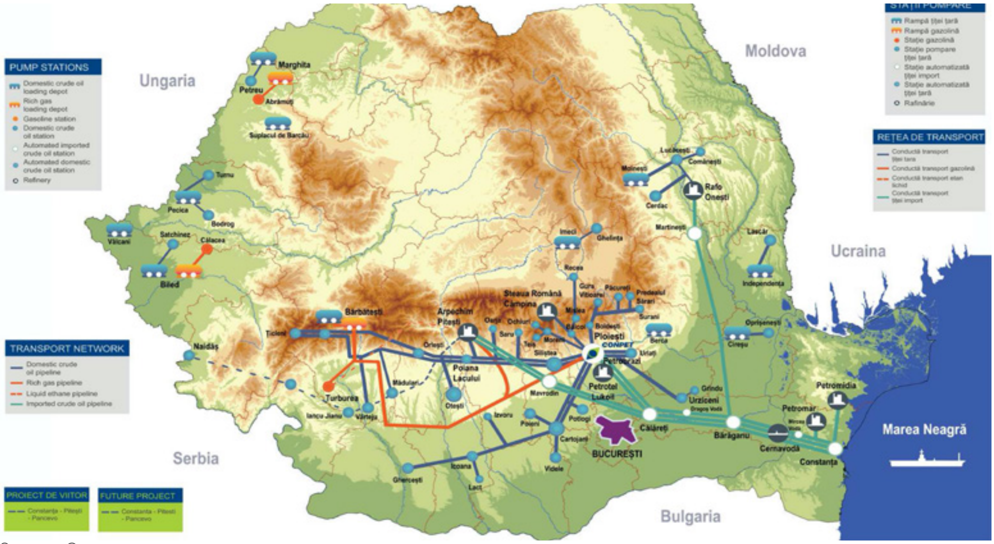
Petrotel-Lukoil is the oldest of these 4 refineries, built in 1904, which is why it was also the first to be modernized. Until 2013-2014, Lukoil's Romanian refinery was the most advanced one in its portfolio of refineries outside Russia (and the only one with a Nelson index of 10 at the time). Following subsequent upgrade and modernization programs in other refineries, this is no longer the case, as the Burgas refinery (Bulgaria) and Isab refinery (Italy) now have a higher Nelson index than Petrotel (in Romania). In terms of refining capacity, Petrotel-Lukoil has the lowest refining capacity (only 2.7 million tons) compared to Burgas (7 million tons) or Isab (14 million tons). Petrotel processes Urals oil and oil produced at Romanian fields. Its refining throughput was 2.485 million tons in 2019.

Table 5.177 **Key figures for Petrotel Lukoil refinery in Romania**

	2015	2016	2017	2018	2019
Refining capacity, mln t/year	2.7	2.7	2.7	2.7	2.7
Nelson index	10.0	10.0	10.0	10.0	10.0
Refinery throughput, mln t	2.237	2.771	2.368	2.723	2.485
Petroleum products output, mln t	2.173	2.709	2.320	2.659	2.368

The refinery is located in Ploiesti, some 55 km away from Bucharest. Crude is delivered to the refinery by railway and via a pipeline from Constanta. Finished products are shipped by railroad and motor trucks.

Map 5.56 **OMV Petrom's oil & gas assets (as of December 2019)**



Source: Conpet

Romania has an extensive crude pipeline system for transporting oil within the country. Romania's crude pipeline system is concentrated almost entirely in the central-southern part (Constanta, Bucharest, the outer Carpathian region). The main gateway for crude import is Constanta. The oil transport system is not connected to any of the neighboring countries and has mostly a domestic purpose. Conpet is the operator of the oil transport system (also referred to as "crude oil, rich gas, condensate and ethane pipeline transport system"). For areas not connected to the transport system, Conpet uses railway tanks.

The National Transport System was built to transport crude from the oil fields to the refineries. The system has 3,800 km of pipelines, out of which 3,161 km are currently used. The system has the following subsystems, grouped according to the transported products:

- **Domestic crude and condensate transport subsystem** (approx. 1,540 km) transports crude oil and condensate produced in OMV Petrom areas to the refineries. The domestic crude oil and condensate production is transported via pipelines, by railway tanks, or combined (rail and pipelines).
- **Rich gas transport subsystem** transports rich gas from the separation units in Ardeal (Biled and Pecica) to Petrobrazi refinery.
- **Ethane transport subsystem** from Turburea ethane separation platform to Arpechim Pitesti refinery. Currently, due to the shutdown of Arpechim refinery, the subsystem is not used, except for one portion of the pipeline which is used to transport condensate from Totea warehouse to Petrobrazi refinery.
- **Subsystem for crude** imports transports crude oil from Oil Terminal Constanta to the refineries in Ploiești, Arpechim-Pitești and Midia.

Three quarters of Conpet's revenues come from the domestic transport of oil -and not from the transport of imported oil- despite the fact that the overall quantities are about the same. The total annual volume transported through the oil pipeline system is 7 million tons, which translates into a transport throughput utilization rate of 40%.

Table 5.178 **Conpet: oil volumes transported and revenues (2017-2019)**

Indicators	M.U.	2019	2018	2017
Quantities transported on the domestic subsystem	Thousand tons	3,487	3,493	3,551
Quantities transported on the import subsystem	Thousand tons	3,637	3,362	3,269
TOTAL TRANSPORTED QUANTITIES	**Thousand tons**	**7,124**	**6,855**	**6,820**

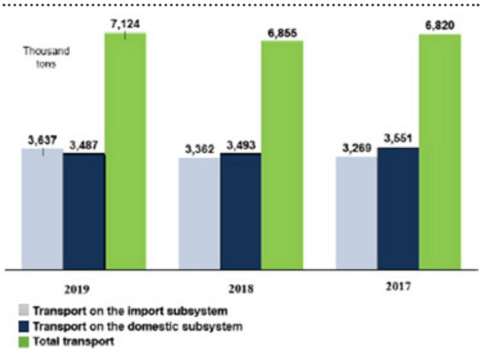
Figure 5.230 **Conpet: oil volumes transported in 2017-2019**



Source: Conpet

Oil transport is a natural monopoly activity, therefore Conpet has no competitors. Tariffs are set by ANRM. They are higher for the use of the domestic subsystem than for the import subsystem. There is also a differentiation in tariff value for the import subsystem based on volume.

Table 5.179 **Oil transport tariffs for the domestic subsystem**

Period	Transport tariff (RON/ton)	Approved by NAMR Order no.
January 01st, 2018 - June 18th, 2018	79.75	32/2016

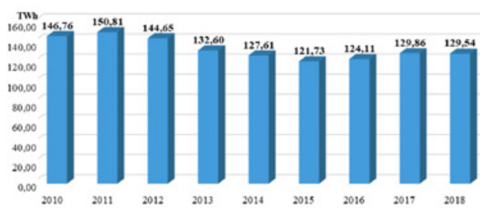
Natural Gas

(a) Natural Gas Supply and Demand

Currently, Romania is the 2nd natural gas producer in the European Union, after Netherlands. Presently, annual domestic production stands at 10 Bcm. Romania is traditionally an onshore gas producer. The most impressive discovery to date – the Neptune gas field in the Black Sea, in 2012 - has not led to an investment decision yet. The first Romanian Black Sea gas may start flowing in 2021 from the Ana and Doina gas fields, part of the Midia project, developed by Black Sea Oil and Gas (BSOG) which will add 1 Bcm/year to the market.

As shown in Figure 5.231, Romania's gas consumption reached a low in 2015 (121.7 TWh), has rebounded since, without however reaching the 2010-2012 levels.

Figure 5.231 **Natural gas consumption in Romania (2010-2018)**

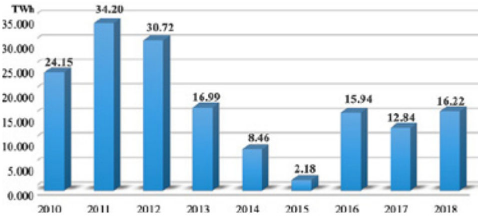


Source: ANRE

Romania's consumption profile is determined by high gas imports during winter and low gas imports during summer (when consumption relies mostly on domestic gas). The highest gas imports in the past decade were recorded in 2011 and 2012, and the lowest gas imports were recorded in 2015 as shown in Figure 5.232.

(b) Natural Gas Imports

Figure 5.232 **Romania's natural gas imports (2010-2018)**



Source: ANRE

Romania achieved full liberalization of its gas market on July 1, 2020. Until June 30, 2020, there was a *de facto* price cap on domestic gas at 68 lei/MWh (€14/MWh). More broadly, the current situation in the gas market is shaped by demand reduction (due to the economic Covid-induced slowdown).

(c) Dependence (%)

It should be noted that, thanks to its sizable indigenous gas production, Romania has the lowest gas import dependency in the region (See Figure 5.233). At present Romania has 44 active concession areas, where the companies involved undertake exploration, development and production activities on the strength of submitted programs approved by ANRM. Map 5.57 shows these active areas.

Figure 5.233 **Share of domestic vs. import gas (2008-2019)**

(e) Infrastructure (Pipelines, Storage)

Pipelines

The National Gas Transmission System is a radial-ring system interconnected with the starting points in the deposit area of Transylvania, Oltenia and Muntenia East, and the destination area of Bucharest-Ploiești, Moldova, Oltenia and Central and North Transylvania. Natural gas is transported via gas pipelines and gas supply connections, a network operating at pressures between 6 and 35 bar. The gas network, which is managed by Transgaz as shown on Map 5.59, is connected to Ukraine, Hungary, Bulgaria and Moldova through seven interconnection points as follows:

- Medieșul Aurit entry point with annual import capacity of 4 bcm (42.2 TWh) and regime pressure of 70 bar;
- Isaccea entry point with an annual import capacity of 8.6 bcm (90.73 TWh) and regime pressure of 55 bar;
- Isaccea 1/Orlovka 1 with capacity of 6.8 bcm/year. Pressure: 49.5 bar at import, 45 bar at export
- Csanadpalota entry and exit point with an annual import capacity of 1.75 bcm (18.46 TWh), 63 bar pressure, an annual export capacity of 0.087 bcm (0.91 TWh) and annual interruptible export capacity of 0.35 bcm (3.69 TWh). As of October 2019, the import capacity grew to 2.2 bcm/year.

After the completion of phase II of the BRUA gas pipeline, the transport capacity towards Hungary will increase to 4.4 bcm/year.

- Iași-Ungheni exit point, with an annual capacity of 1.5 billion cubic meters (15.8 TWh), 50 bar.
- Giurgiu-Ruse entry/exit point, with annual capacity of 1.5 bcm from Romania to Bulgaria and 0.5 bcm from Bulgaria towards Romania. Pressure: 40 bar at export, 30 bar at import.
- Negru Voda 1/ Kardam with a capacity of 6.4 bcm at export, 55 bar pressure.

Romania's maximum annual import capacity is 14.35 bcm (151.39 TWh). The nominal annual export capacity is 1.58 bcm (16.74 TWh). Physical gas export is possible only with Hungary (Csanadpalota), Bulgaria (Giurgiu-Ruse) and Moldova (Iasi-Ungheni).

Source: SNAM-BCG (2017), ENPG (2018)

Romania's flagship project in the last 5 years (2015-2020) has been the BRUA (Bulgaria – Romania – Hungary – Austria) pipeline. While Hungary has extracted itself from the original route, Romania pressed ahead in completing phase I of the project on its territory. The BRUA project was initially designed along 3 stages, of which only the first one has been realized:

Phase I

- is considered a Security of Supply project (SoS)
- Cost: €478.6 million, of which €179.3 million come from the EU.
- Construction start: June 2018
- Completed: November 2020

• Status: As of now, it is "a pipeline from nowhere to nowhere". The pipeline links the Romanian Black Sea gas to export gas markets in Central and Eastern Europe. It was supposed to carry natural gas (yet to be produced) and transport it through Hungary further to Austria. Hungary has chosen instead to be part of the alternative Russian project (Turkish Stream), making the Romanian gas unnecessary, since Bulgaria, Hungary and Serbia all signed on to the Russian project, making the Romanian leg irrelevant.

Phase II

- Considered a commercial project (will go ahead only if commercially viable)
- Lack of market interest
- Cost: €74.5 million
- Status: cancelled

Phase III – a back-up plan for phase II, in case additional gas volumes require transportation in excess of the volumes shipped West through BRUA stage II. Currently not applicable.

Storage

Romania's current nominal storage capacity is 4.5 bcm /cycle (47 TWh), with a regular use of 3 bcm/cycle (31 TWh). There are two storage operators: Romgaz (Depogaz) and Depomures. There are 6 UGS set up in depleted reservoirs, five of which are operated by Romgaz (total capacity of 2.76 bcm), and only one by Depomures (0.3 bcm). Table 5.182 shows the status of Romania's underground gas storage facilities.

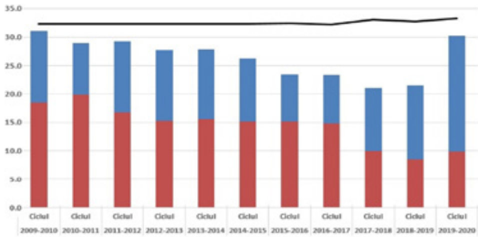
Table 5.182 **Capacity of underground gas storages (UGSs)**

Storage name	Operator	Active capacity (TWh/cycle)	Extraction capacity (GWh/day)	Injection capacity (GWh/day)
Balaceanca	Depogaz	0.5452	13.176	10.98
Bilciuresti	Depogaz	14.3263	152.782	109.13
Ghercesti	Depogaz	1.6343	21.4	21.4
Sarmasel	Depogaz	9.5987	79.035	68.497
Urziceni	Depogaz	4.0168	50.157	33.438
Targu Mures	Depomures	3.1545	29	27
Total		**33.2758**	**345.55**	**270.445**

Source: Transgaz, PDSNT 2020-2029

Storage is not very flexible, as it was mainly developed to deal with seasonal variations, and hence, the rate of injection/extraction is not designed for fast commercial use. Tariffs for gas storage are regulated.

Figure 5.234 **Reserved gas storage capacity (2009-2019)**



Note: color code: red = producers, blue = others, black = technical capacity   Source: Transgaz

As Figure 5.234 shows, in the previous 4 cycles before the last one, storage usage dropped below 25 TWh, and climbed back to 30 TWh in the 2019-2020 cycle, reflecting a wider stock build up and glut in the market. In addition, national legislation now obliges gas suppliers to hold minimum required quantities for each market segment.

(f) Domestic Gas Market

The Romanian gas market is highly concentrated on the production side, it is essentially an oligopolistic market, with 2 big players: Romgaz and OMV Petrom (together they account for 90% of the domestic gas production). The other players are Amromco Energy, Serinus Energy Romania, Stratum Energy Romania, Raffles Energy, Mazarine Energy Romania, Hunt Oil Romania, and Foraje Sonde. It is a less concentrated market on the supply side, with 84 gas suppliers and 31 gas distributors.

Gas transport, storage and distribution is regulated, while the rest of activities are conducted in the free market on a competitive basis. In Romania, households account for up to 30% of gas consumption, while industry and commercial end-users account for 70%. Households in urban areas use natural gas, while in the countryside it is largely biomass

5

(firewood) that is used for heating and cooking. There are 3.6 million residential consumers. Gas supply in the residential sector is dominated by Engie and E.ON, which together account for 90%.

Industry: The non-residential consumers (industry, electricity production, district heating, chemical industry) amount to 200,000. OMV Petrom is an important supplier to large industrial customers and commercial customers (businesses, small industrial customers), but is not present on the residential segment. Both Romgaz and Petrom's domestic production, but also imported gas, supply the chemical industry which is one of the biggest consumers. **Azomures** (the biggest producer of fertilizers, since 2011 owned by Swiss company Ameropa) is now the main industrial **consumer of gas**, especially since Interagro's plants have closed down or have been under restructuring following bankruptcy procedures in the past years.

District heating: CHPs are major users of natural gas, with ELCEN (the main supplier of heat in Bucharest) being the biggest such customer. Romgaz is the main gas supplier for CHPs. Many coal-fired power plants have switched in recent years to natural gas in order to comply with stricter environmental standards. This trend will continue in the coming years, with natural gas displacing coal-fired power generation, especially in cogeneration.

Utilization of natural gas (CH4) in transport is incipient. Despite having domestic gas production, Romania did not give too much thought until now to natural gas as an alternative fuel (as CNG or LNG) for sustainable transport. No LNG re-fueling infrastructure exists to date.

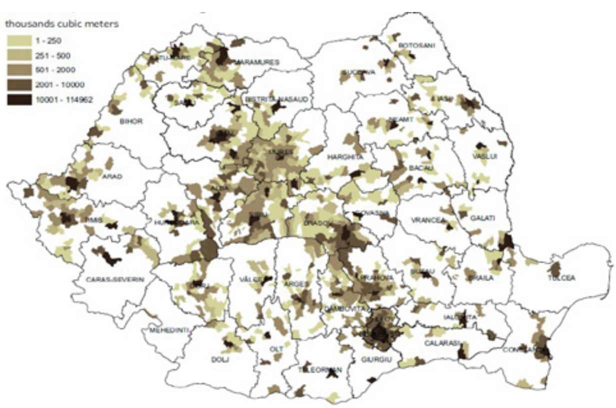
(g) National NG policy - strategic plan

At EU level, there is a major shift away from natural gas under way. Financial institutions (such as the European Investment Bank) have excluded fossil fuel projects (including gas) from future financing, with EBRD and some commerce banks following suit. As climate finance develops further driven by EU's aggressive decarbonization agenda, this will reduce funding opportunities available for gas projects.

In Romania, it took more than 10 years for decision-makers to understand that natural gas is a transition fuel (hence its days are numbered). Therefore, the upcoming decade presents a last window of opportunity to invest in domestic gas related infrastructure. Despite being a gas producer since 1909, Romania's gas grid covers less than half of the country's household use (estimates range between 35% and 40% in terms of household that have access to the gas grid).

The prevailing situation concerning household use is clearly shown on Map 5.60.

Map 5.60 **Consumption of natural gas for household use**



Source: ANRM

In October 2020, Romania's president approved **Law no. 214**, which enacts GEO no. 128/2020 which creates a **National program for connecting the population to the gas grid**. The law creates the possibility for the costs of connecting to the gas grid to be covered by EU funds during 2014-2020 (under LIOP, Axis 8)[4] as well as in the upcoming 2021-2027 period[5]. The funding will support the „transformation of existing natural gas grids into smart gas distribution grids".

In September 2020, the EU Parliament has passed an amendment which would allow EU countries to use the Just Transition Fund also for natural gas projects in coal dependent monoindustrial regions. This keeps the door open for gas as a transition fuel in the next decade.

On the upstream side, 6 years were lost (between 2012-2018) without adopting a fiscal regulatory framework for Black Sea gas development. When finally it was adopted in 2018, the oil and gas companies did not like it and held back on making an investment decision. Furthermore, with the changed global circumstances (gas glut and demand destruction), Exxon wants to exit the Romanian Black Sea, and so does Lukoil. Both are looking to sell their shares in the offshore concession areas where gas discoveries were made.

Onshore, the situation does not look any better. Excessive and haphazard regulation (such as the price freeze at 68 lei for sale of domestic gas to end-consumers in 2019-2020) resulted in over-taxation of domestically produced gas in comparison to imported gas (which was not subject to these additional taxes), and led to an increase of gas imports in 2019 and the shutdown of some domestic gas wells deemed unprofitable (mostly belonging to Romgaz). At the same time, a dash for gas in power generation has been underway since 2015, with more and more CHPs gradually switching from coal to natural gas in Romania.

(h) Planned new projects

The biggest development in natural gas was supposed to be the start of gas production in the Romanian Black Sea, which was expected in 2018. However, 8 years since the gas discovery was first made in Neptune Deep in 2012, no FID has been taken. Exxon wants out of the perimeter and has been looking for two years for potential buyers of its 50% stake. Finally, after much foot dragging and other proposals under consideration, Romgaz submitted a bid to buy Exxon's share of the perimeter for €900 million in early April 2021.

If Romania manages to get its act together and kickstart production of Black Sea gas, that would be the biggest development in the natural gas market.

Solid Fuels

(a) Supply and consumption

In 2020, Romania had 4,787 MW of coal-fired installed capacity which accounted for 23% of its total installed capacity. In its initial INECP (2019), Romania outlined a moderate reduction in net installed coal capacity (from 5.5 GW in 2019 to 3.2 GW in 2030) – a reduction of 2.3 GW in the span of a decade. Retirement of coal-fired capacities started with the write-off of obsolete units (which existed on paper only, labeled as "reserves", but were not functional in practice). Nevertheless, Romania does not yet have an official coal phase-out strategy, with a clear commitment to back away from coal. Instead, the country has an ambivalent position on the issue of coal phase-out. On the one hand, it plans to retire 2.3 GW of coal capacity by 2030, but on the other hand, it shies away from adopting a coal phase-out strategy or making an explicit time-bound commitment, and tends to avoid the topic of coal phase-out in public discussions. This is complicated by the fact that there are regions in Romania (such as Hunedoara, with 1,225 MW installed

[4] The National program financed from EU funds allocated for 2014-2020 will run until December 31, 2023.
[5] The National program financed from EU funds allocated for 2021-2027 will run until December 31, 2029.

coal capacity) where no alternative to coal generation has been put in place yet. Which is why old powerplants have to function partially (at minimum 400 MW) for system stability reasons until the end of 2020, despite being practically bankrupt.

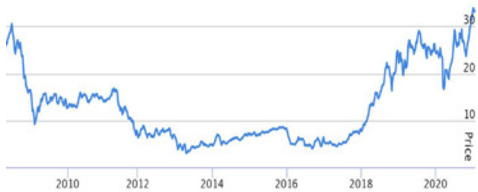
The entire coal production of Romania is used for heat and power generation. Hard coal is mined by Complexul Energetic Hunedoara (CEH) and lignite by Complexul Energetic Oltenia (CEO). Complexul Energetic Oltenia (CEO)'s power plants run entirely on lignite (3,240 MW in total) while Complexul Energetic Hunedoara's power plants run entirely on hard coal (1,225 MW, as shown in Table 5.183.

Table 5.183 **Coal-fired power generation in 2017**

Power supply		2017
Total gross power generation	TWh	64.3
Net power imports (exports)	TWh	(2.9)
Total power supply	TWh	56.0
Power generation from hard coal	TWh	1.2
Power generation from lignite	TWh	15.6
Hard coal power generation capacity	MW gross	1 225
Lignite power generation capacity	MW gross	3 240

The pressure to decarbonize grew in 2018-2020, especially after the price of carbon emissions under the EU ETS jumped significantly, as shown in Figure 5.235. This has put even more pressure on coal-fired power generation. In order to benefit from state-aid, some producers have agreed to restructure completely. This is the case of Complexul Energetic Oltenia which has tabled an ambitious plan to reorganize its assets, by abandoning coal-generation entirely and replacing it with natural gas and renewables in the coming years.

Figure 5.235 **EAU price evolution**

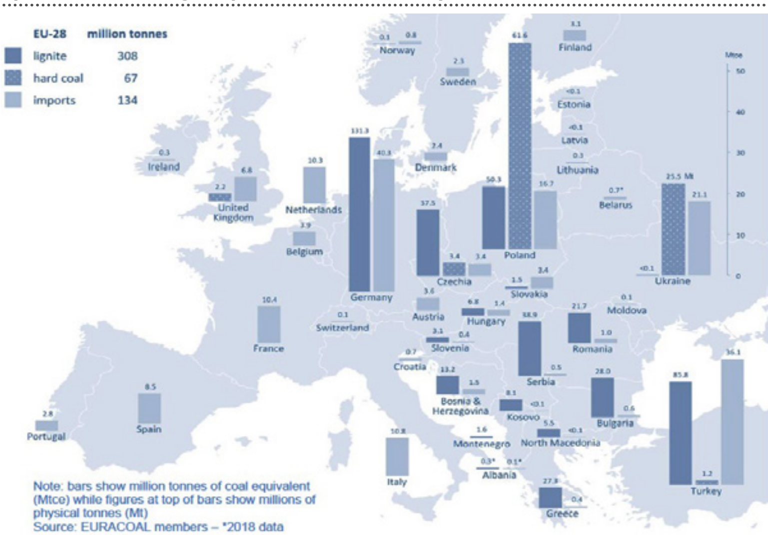


Source: Ember

(b) Local production and exploration

Romania ranks fifth in the EU by domestic coal production (after Germany, Poland, Bulgaria, and Greece) and 7th on the European continent (with Turkey and Ukraine having a larger coal production than Romania). Map 5.61 shows the prevailing situation in Europe and Turkey.

Map 5.61 **Europe: hard coal and lignite production and coal imports in 2019**



Source: ANRM

(c) Deposits

Hard coal resources are estimated at 2,446 million tonnes, of which 11 million are economically recoverable. Lignite resources are estimated at 9,640 million tonnes, of which 280 million tonnes are proven reserves. Almost 90% of lignite is located in Oltenia basin and 80% can be surfaced mined. Table 5.184 shows Romania's coal resources and reserves.

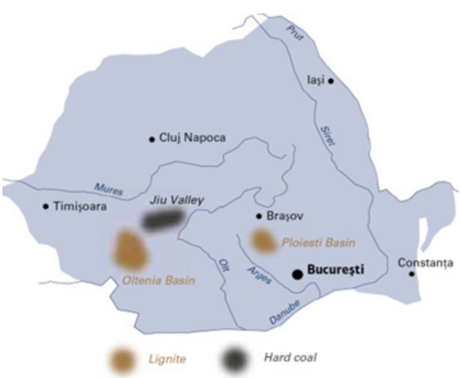
Table 5.184 **Romania's coal resources and reserves**

Coal resources and reserves		as at 1.1.2018
Total resources hard coal	Mt	2 446
Total resources lignite	Mt	9 920
Reserves hard coal	Mt	11
Reserves lignite	Mt	280

The Romanian government agreed in 2011 to close the loss-making mines. The closure targets only unprofitable mines. The following hard coal mines have been closed: Petrila mine (oldest in Romania) in 2015, Paroşeni and Uricani mines in 2017, Lonea and Lupeni (in 2018). Only two hard coal mines are still being exploited: Vulcan and Livezeni (belonging to CEH).

In terms of lignite mines, the following are scheduled to be closed: Rovinari, Husnicioara, Lupoaia, Pesteana (which belong to CEO). Map 5.62 shows the geographic location of the above mines.

Map 5.62 **Location of lignite and hard coal deposits**



Source: Euracoal

(d) Core imports

Romania imported 0.9 Mt of coal in 2018. No coal was exported in that year.

(e) Planned new projects: There are no new coal projects under consideration.

Electricity

(a) Electricity supply and demand (in TWh)
Romania's gross electricity production in 2019 was 59.5 TWh – almost the same as a decade ago (60.8 TWh in 2010) as shown in Figures 5.236 and 5.237 which provide further information on electricity consumption patterns.

Figure 5.236 **Actual annual gross electricity production in Romania (2010-2019)**

Figure 5.237 **Average net consumption 2017-2019 (MWh/h)**

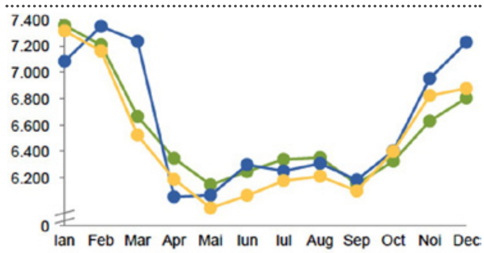

Table 5.185 **Maximum hourly consumption (2017-2019)**

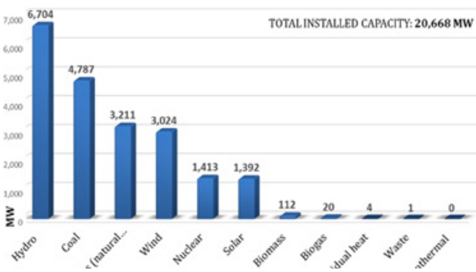
Year	Month	Value (MWh/h)
2017	January	8,940
2018	February	8,920
2019	January	8,812

Source: Transelectrica data

b) Installed Capacity (in MW)

The evolution of Romania's installed electricity capacity is shown in Table 5.186, while Figure 5.238 depicts the installed capacity per source for 2020. The total installed capacity has steadily been decreasing in late years on account of thermal units scale down as RES capacity is moving upwards.

Figure 5.238 **Installed capacity per source (in MW)**



Source: ANRE data, 2020

In terms of installed capacity in MW, hydro has by far the largest capacities, see figure above.

Table 5.186 **Evolution of installed capacity (2017-2019)**

MW	2019	2018	2017
Termo	8.026	11.888	12.029
Nuclear	1.413	1.413	1.413
Hidro	6.704	6.759	6.761
Regenerabile	4.553	4.546	4.535
Total	20.696	24.606*	24.738

Source: Transelectrica
Note: thermal means coal + natural gas

Electricity imports - exports

Table 5.187 **Electricity balance (2017-2019)**

Year	2017	2018	2019
Net domestic production	59.8 TWh	60.7 TWh	56 TWh
Import	3.2 TWh	2.8 TWh	5.5 TWh
Export	6.1 TWh	5.4 TWh	4 TWh
Net domestic consumption	56.9 TWh	58.1 TWh	57.5 TWh

Source: Transelectrica

Tariffs

Electricity transport is a natural monopoly activity and tariffs are regulated. As of January 2021, ANRE set the following tariffs for electricity transmission as shown in Table 5.188:

Table 5.188 **Transmission tariffs in 2021**

Tariff type	Lei/ MWh	€/MWh
Average tariff for electricity transport	20.55	4.22
TG – tariff for injecting power in the grid	1.3	0.27
TL – tariff for extracting power from the grid	19.22	3.95
Tariff for system services	11.96	2.46

Source: ANRE Order no. 214/ December 9, 2020

(c) Cross-border interconnections:

There are 16 cross-border electricity interconnections which are summarized in Table 5.189.

Table 5.189 **Cross border power lines**

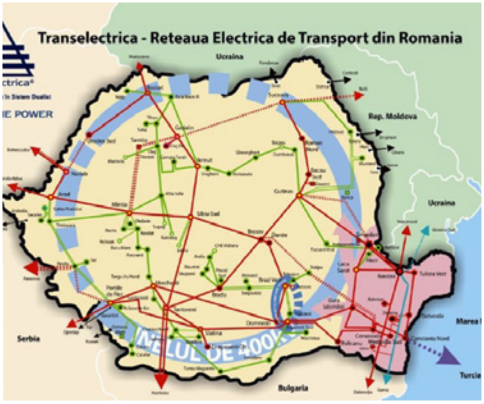
Order no.	Border	OEL interconnection
1	Bulgaria	400 kV Ţânţăreni – Kozlodui OPL
2	Bulgaria	400 kV Stupina – Varna OPL
3	Bulgaria	400 kV Rahman – Dobrudja OPL
4	Serbia	400 kV Iron Gates – Djerdap OPL
5	Serbia	400 kV Reşiţa – Pancevo OPL
6	Serbia	110 kV Jimbolia – Kikinda OPL
7	Serbia	110 kV Gura Văii – Sip OPL
8	Serbia	110 kV Ostrovu Mare – Kusjak OPL
9	Hungary	400 kV Arad – Sandorfalva OPL
10	Hungary	400 kV Nadab – Bekescsaba OPL
11	Ukraine	400 kV Roşiori – Mukachevo OPL
12	The Republic of Moldova	400 kV Isaccea – Vucăneşti OPL
13	The Republic of Moldova	110 kV Stânca – Costeşti OPL
14	The Republic of Moldova	110 kV Cioara – Huşi OPL
15	The Republic of Moldova	110 kV Ţuţora – Ungheni OPL
16	The Republic of Moldova	110 kV Falciu – Goteşti OPL

Source: Transelectrica, ETG Development Plan for 2018–2027, Annex B-2, Electricity Transmission Grid in Romania, http://www.transelectrica.ro/web/tel/transport-detalii

(d) **Planned new projects focus mostly on the domestic level.** Transelectrica considers as priority the following projects to be completed by 2030:

- 400 kV OPL Nădab – Oradea South;
- 400 kV OPL Iron Gates - Reșița and extension of 220/110 kV Reșița Station by building a new 400 kV station;
- 400 kV OPL in double circuit Cernavodă – Stâlpu, with an entry/exit circuit in Gura Ialomiței station;
- 400 kV OPL in double circuit Reșița - Timișoara - Săcălaz, including construction of the 400 kV Timișoara station;
- 400 kV OPL in double circuit Smârdan – Gutinaș;
- 400 kV OPL in double circuit Timișoara – Săcălaz - Arad, including the construction of the 400 kV Săcălaz station and extension of the 400 kV Arad station.

Map 5.63 **Romania Electricity Transmission network**



On account of these projects Romania aims to achieve a 15.4% rate of interconnectivity by 2030.

Renewables

(a) Overview of the sector's development

Significant investments (€8 billion) made in the renewable energy sector during 2010-2015 led to 5 GW of new renewable energy sources (RES) capacity being added. It must be mentioned however that, in RES Romania started from a strong position due to the existence of a large hydro base. To date, its hydro capacity remains the largest in the country (6,704 MW of installed capacity). On the other hand, geothermal capacity continues to remain underdeveloped (below 1 MW). No significant new RES capacities were added during 2017-2019.

To date, most of the investments in new RES capacities built in Romania were carried out by foreign companies, with little to no interest (until 2020) from the large state-owned enterprises (SOEs), with the exception of Hidroelectrica.

The biggest investors in wind are CEZ (600 MW in total), Enel Green Power Romania (499 MW), Energias De Portugal Renovaveis - EDPR (386 MW), Verbund Wind Power Romania (226 MW), STEAG (108 MW), IKEA (123 MW), Engie (98 MW), and Lukoil (84 MW). CEZ sold its Romanian assets to Macquire Infrastructure and Real Assets (MIRA), an Australian investment fund in a transaction valued over €1 billion, a record amount for Romania, where only three other M&A transactions ever exceeded this threshold (Erste-BCR; Vadofone-Connex, and Rompetrol - KMG).

The biggest projects in solar energy belong to Samsung (98 MW in total), GPBS Solaris 48 (56 MW), Green Vision Seven (46 MW), Enel Green Power Romania (34 MW), XPV (23 MW), EDPR (22 MW), Eye Mall (20 MW) and WDP Development Romania (12 MW).

The largest investors in small hydro projects are Hidroelectrica (38 MW in total), Elsid SA (36 MW), CEZ through TMK Hydroenergy power (22 MW), Vienna Energy Forta Naturala (20 MW), MHC Water Power (15 MW), Electrocarbon (14 MW) and Luxten Lighting Company (9 MW).

The largest biomass projects belong to Bioenergy Suceava (30 MW), Holzindustrie Schweihofer (21 MW), Bio Electrica Transilvania (20 MW), and Egger Romania (15 MW).

Currently, **Romania has no offshore wind capacity.** Moreover, there is a significant onshore wind potential that remains unexploited, estimated at 9.0 GW of the 12 GW overall.

With the exception of Hidroelectrica, the majority of the state-owned enterprises (SOEs) have largely been indifferent to renewable projects during the peak years of RES development in Romania (2011-2015). This is now changing. The new government policy is to encourage diversification of the power generation portfolio of SOEs, moving away from the hitherto business model of power generation by one energy source which existed between SOEs (Hidroelectrica for hydro generation, Romgaz for natural gas, Oltenia and Hunedoara for coal). This trend will only speed up in the context of the Green Deal and as funding for green infrastructure projects is becoming available in the coming years.

(b) Latest legislation, incentives and national RES policy

Romania's Integrated National Energy and Climate Plan (INECP) aims for a share of 30.7% from RES in gross final energy consumption by 2030. This target is a step-up from 27.9% which was included in the first draft (December 2018). In its final version Romania's INECP (April 2020), Romania increased the target to 30.7% (a level still considered conservative by the EC, which recommended a RES target of at least 34%). In order to achieve this target, an additional 6.9 GW of renewable generation should be added by 2030, compared to 2015. Fortunately, Romania possesses a generous potential when it comes to RES. According to a study by Deloitte, Romania's renewable potential by RES type is:

- 54 GW in solar (19 GW industrial, 35 GW rooftop)
- 16 GW in wind (12 GW onshore, 4 GW offshore)
- 11 GW in hydro

The two main non-technical barriers that, if removed/solved, could allow additional RES development are:

- allowing conclusion of Power Purchase Agreements (PPAs)
- the possibility to use EU funds for power grid consolidation, in areas where new RES projects are located, in order to facilitate integration of RES into the grid.

(c) Installed capacity per source (in MW)

Table 5.190 **Accredited RES-E producers (2018)**

RES technology	Number of producers	Installed capacity	Share of accredited RES-E
Wind	66	2,961 MW	62%
Small hydro (<10 MW)	102	341 MW	7%
Solar PV	576	1,359 MW	28%
Biomass	28	124 MW	3%
Total	772	4,785 MW	100%

Source: ANRE National Annual Report for 2018

(d) Planned new major projects

There is an interest in offshore RES potential signaled by Hidroelectrica (the largest RES player, entirely state-owned) which stated its intention to build 300 MW of offshore wind, as well as from the banking sector.

Romgaz (a traditional natural gas producer) is planning to build 250 MW of RES capacity in the next five years (2020-2025), according to the National Investment and Economic Recovery Plan of July 2020.

The largest coal producer, Complexul Energetic Oltenia (CEO), has tabled a restructuring plan that aims to "decarbonize" its electricity production by building 8 PV parks (totaling 700 MW) and 2 small hydro projects (12 MW), but also replacing all of its coal-fired generation capacity with natural gas-fired units by 2026.

Energy Efficiency and Cogeneration

Romania aims to achieve **10 million toe of cumulative energy savings** between 2020 and 2030. Investments will be concentrated in 2020-2025, with effects to be felt from 2025 onwards. Table 5.191 shows the targeted energy savings for 2021-2030.

Table 5.191 **Target energy savings for 2021-2030 based on avg. final energy consumption (2016-18)**

Year	Annual energy savings										TOTAL
2021	0.11										0.11
2022	0.11	0.11									0.23

Source: INECP

Romania plans to seriously focus on buildings and has drafted a National long-term strategy for building renovation (2020-2050), which was approved by the government in November 2020. The strategy targets an annual increase of energy savings from 0.03 Mtoe (in 2021) to 0.83 Mtoe (in 2030) – a total of **3.4 Mtoe in energy savings in the building sector** is foreseen for the next decade. Table 5.192 shows the energy efficiency targets for the residential sector for 2021-2030.

Table 5.192 **Energy efficiency in residential sector to be achieved in the period 2021-2030 [Mtoe]**

Year	Energy saving in the residential sector										TOTAL
2021	0.03										0.03
2022	0.03	0.04									0.07

TOTAL cumulated energy efficiency in the residential sector in the period 2021-2030											3.4

Source: World Bank, INECP

The National long-term strategy for building renovation (2020-2050) considered 3 scenarios for building renovation which differ in terms of renovation speed, in comparison to the baseline (current annual renovation rate of the building stock of just 0.5%). Scenario 1 assumes a gradual increase of annual renovation rate over the next 3 decades. Scenario 2 assumes an aggressive increase of the annual renovation rate in the first decade (2020-2030). Scenario 3 assumes a relative constant annual renovation rate of 3-to-3.6% over the entire period. The various scenarios are shown in Table 5.193.

Table 5.193 **Scenarios for building renovation in 2020-2050**

	Annual renovation rates 2021-2030	Annual renovation rates 2031-2040	Annual renovation rates 2041-2050
Baseline scenario	0.50 %	0.50 %	0.50 %
Scenario 1	Gradual increase from 0.53 % to 1.56 %	Gradual increase from 2.22 % to 4.78 %	Gradual increase from 4.85 % to 6.41 %
Scenario 2	**Gradual increase from 0.69 % to 3.39 %**	**3.79 %**	**4.33 %**

Source: World Bank, INECP

The strategy ultimately chose Scenario 2 which was included in the *National Integrated Energy and Climate Plan* that Romania submitted to the European Commission in 2020. The implications and required investments to achieve scenario 2 are summarized in the Table 5.194.

Source: Romania's long-term renovation strategy for 2020-2050

According to the strategy, the investment requirement to achieve scenario 2 is estimated at 12.8 billion EUR. The funding for energy efficiency programs could come from:

- State budget or EU funds: 5 billion EUR, of which 3 billion EUR non-reimbursable grants;
- Reimbursable grants/loans: 6-to-9 billion EUR;
- Owners' co-financing: 1.8 billion EUR.

The following years will present an auspicious period for energy efficiency projects in Romania, with a variety of funding instruments available for all types of green projects. A general overview of the main European financing channels is provided in Table 5.195.

On top of the funding it receives for the 2021-2027 under the classic EU budget (EU Multiannual Financial Framework), Romania is earmarked to receive €30 billion from the Recovery and Resilience Facility. A part of these resources will be channeled towards building renovation.

Table 5.195 **Overview of main EU funds available to Romania in 2021-2027**

Program	Amount	Comment
Cohesion Policy Funds (ERDF, ESF+, Cohesion Fund)	€29.2 billion	Does not include sums under Connecting Europe Facility.
Recovery and Resilience Facility	€30 billion (approx.)	€13.8 billion of which will be grants.
Just Transition Fund	€3.5 billion	Amount was increased in September from €1.7 billion
Modernization Fund	€3 billion	approximation
ETS auction revenue	€0.7 billion	Revenues from auctioning of allowances under the EU Emission Trading System (ETS); approximation.

On April 7, 2021, the Romanian government approved the National Recovery and Resilience Plan (NRRP), the final version of which will be submitted to the European Commission by May 31, 2021. Building renovation is included under pillar I (Green Transition) and named "Renovation Wave – Fund for green and seismic renovation" (I.5). Its initial negotiating budget is €2.2 billion. Renewable energy is also part of pillar I (Green Transition), and is titled "Renewable energy and energy efficiency" (I.6.) and is allocated an initial negotiating budget of €1.3 billion. However, the numbers in the NRRP are not final yet, and are change following the feedback received from the European Commission.

(d) Cogeneration: Regulatory framework, installed capacity

Romania has a cogeneration bonus (introduced by GD 1215/2009). It is a support scheme that was approved by the European Commission as state aid and became operational on April 1, 2011. The bonus is granted upon request, for electricity produced by high efficiency cogeneration units, which must be included in an approved producers list. The bonus can be granted also to producers who replace, on the same site, old capacities with new ones. The scheme was amended in 2016 to extend also to cogeneration units of less than 1 MW. The state aid is granted for operation and is meant to cover the difference between costs and revenues, allowing a rate of return (RoR) of maximum 9%. It is granted for maximum 11 years, until the end of 2022.

The level of the bonus is set annually by ANRE. The bonus has a reference value for each fuel used as feedstock (coal or natural gas). Its value is adjusted annually based on the following factors: average price of fuel, average price of CO_2 certificate, average price of electricity on DAM, and inflation. In case of overcompensation, a producer can be granted a bonus which is lower than the reference bonus. The contribution for cogeneration is collected from all electricity consumers as a unitary tariff applied on the electricity bill. This contribution is not applied to exported electricity (exemption as of July 2014). In 2019, the value of the bonus was 11.86 lei/MWh in the first semester and 15.64 lei/MWh in the second. The value of the cogeneration bonus for the first half of 2021 was set at 17.12 lei/MWh, valid from January 1, 2021 until June 30, 2021. The bonus is not granted to capacities that have been completely depreciated. The maximum capacity that can benefit from the support scheme over its duration is 4,000 MW. Once this limit is reached, only new capacities (that replace existing ones) can be granted support, in excess of this limit. In 2020, the number of companies that benefited was 36, as shown in Table 5.196.

Table 5.196 **Accredited cogeneration assets for 2020**

(e) Planned new major projects

The current support scheme (cogeneration bonus) ends in 2022. Romania wants to extend it, and has submitted a proposal to the EC in this regard. If approved, the new support scheme will apply as of March 2022. The new support scheme should be optimized since the previous one failed to attract any new investments in high efficiency cogeneration since 2015.

It is expected that the new conditions will be stricter and much more difficult to comply for older cogeneration units. It is largely believed that the 2011 support scheme was used more to cross-subsidize and keep on life support older capacities (of Complexul Energetic Hunedoara, CEO, ELCEN Bucharest, ELCEN Galati, CET Govora), instead of serving its primary purpose – that of incentivizing the construction of new cogeneration units. The lack of investments in any new capacities after 2015 is a case in point confirming that the 2011 support scheme was highjacked and redirected to serve another purpose (i.e.: delay reform and artificially keep alive outdated generation capacities). In the past year (2019), under pressure to decarbonize and move away from coal, many new cogeneration projects have been announced. Most of the planned capacities are natural gas-fired ones. The largest investment in such capacities is expected to be made by Complexul Energetic Oltenia (CEO) – which alone will account for 1,400 MW of the new installed gas-fired capacity. Table 5.197 shows the status and plans for gas-fired capacities.

Table 5.197 **Planned gas-fired capacities (selection)**

Program	Amount	Owner	Status and plans
CCGT Iernut	430 MW	Romgaz	To be completed by June 2021
CCGT Mintia	400 MW	Romgaz	Feasibility study; could be operational by 2022
Craiova 2	200 MW	CEO	Feasibility study; operational by 2024
Isalnița	800 MW	CEO	Coal-to-gas switch; operational by 2025
Turceni	400 MW	CEO	Coal-to-gas switch; operational by 2025
ALRO	467 MW	ALRO, Romgaz	n/a. 300 MW for Alro's own consumption, 100 MW earmarked for sale on the power market
Halanga	150 MW	Romgaz, GSP	Proposal, MoU signed in September 2020
CCGT Midia	73 MWe	Rompetrol Group	Funded through the Romanian-Kazakh investment fund; deadline n/a
Titan	50 MW	Titan Power SA	deadline n/a.

Note: CEO = Complexul Energetic Oltenia

The Iernut CCGT (430 MW), a Romgaz project initiated in 2013 and still not completed, has had a rocky evolution. Romgaz signed a contract for a turn-key project with a JV made up of Duro Felguera (Spain) and Romelectro (largest Romanian contractor) in 2016.

The project is the first greenfield investment made by the Romanian state (Romgaz is a majority state-owned company) in the past 30 years. The project was meant to mark Romgaz's entry into a new market (electricity production). Estimated at €268 million (without VAT), the contract has experienced cost and time overruns. Things are advancing so slow that Romgaz announced it wants to cancel the contract altogether (currently under discussion with the JV). However, we could use the cost of Iernut (€300 million) as proxy for building 400 new MW, to estimate the cost of adding 3,000 MW of new generation capacity to be at least €2 billion until 2030.

Energy Investment Outlook

The investment requirement in the energy system (only on the demand side) until 2030 was estimated back in 2018 to be €20 billion on average (with a minimum of €15 billion and a maximum of €30 billion).

This estimate was made *before* the Green Deal, so it does not reflect the new EU level of ambition for clean energy. It is, therefore, safe to conclude that the updated investment requirement should be at least **€28-30 billion**, that being a conservative (a minimum) figure to include all investments made (private, public and EU-funds) and distributed as follows by sector:

- RES and storage: €15-17 billion (could go as high as €20 billion if offshore wind takes off)
- Grids (electricity, heat, natural gas): €3 billion
- Buildings: €4 billion
- Nuclear: €4 billion
- «Natural gas-fired generation: €2 billion

Table 5.198 **Estimated investments by energy sector in Romania until 2030**

Sector	Technology type	Capacity	Comment
Nuclear	CANDU (unit 3 of Cernavoda NPP)	700 MW	Estimated investment of **€3.5-4 billion** for unit 3 of Cernavoda NPP, to be put in operation by 2030-2031. Construction start planned for 2024
Hydro	units>10 MW	1,000 MW	Total targeted new capacity in all RES is 6.9 GW by 2030. Estimated investment requirement: **€15-17 billion**
RES	Wind + PV	5,900 MW	
Natural gas	CCGT+CHP	3,000 MW	of which 1,400 MW (gas-fired CCGTs) will belong only to Complexul Energetic Oltenia (CEO) Estimated investment requirement: **minimum €2 billion**
	grid development	n/a	
Energy efficiency	Building renovations	100,000 buildings	**€4 billion**

Source: compiled by author

In the version of the National Recovery and Resilience Plan adopted on April 7, 2021, energy is allocated €4.1 billion: €2.2 billion (building renovations), 1.3 billion (RES and energy efficiency), €600 million (natgas and hydrogen infrastructure). An additional €6-7 billion is available for clean energy projects under the Modernization Fund. Another source of funds is the MFF 2021-2027.

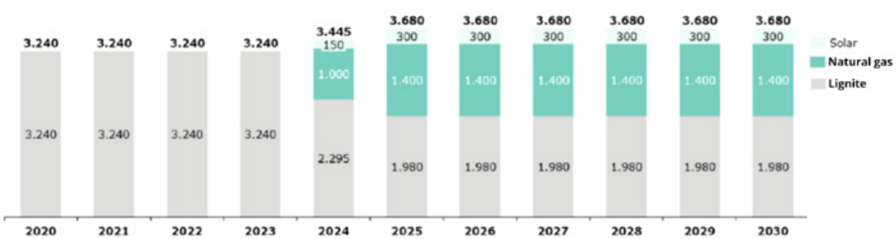
Nuclear

The latest available study estimated the construction cost for both Cernavoda NPP units (number 3 and 4) at €7 billion, meaning €3.5 billion per each unit. The figure has to be updated, but it is realistic to assume €4 billion/unit, given the cost inflation associated with nuclear projects.

Coal phase-out

Although not spoken of explicitly, with no official national calendar for retiring coal generation, with no commitment to a clear deadline, and no coal phase-out strategy, Romania will nevertheless go through this process. In fact, it already is. In February 2020, the Romanian government received the approval from the European Commission to grant a €251 million loan to Complexul Energetic Oltenia (CEO) – the largest coal-fired electricity producer - to help the company buy CO_2 certificates. The cost of CO2 certificates went up significantly in the past 2 years (accounting for 41% of the company turnover in 2018, and 45% in 2019). The loan was to be repaid in 6 months. Since this did not happen, the company opted to send the Commission a restructuring plan (meant to restore profitability). This is how the Decarbonization Plan of Complexul Energetic Oltenia came to be written. If carried out, it will be one of the most significant developments in power generation in the next decade. Currently entirely coal-based (all 3,240 MW), Complexul Energetic Oltenia (CEO) plans to reduce its coal-fired generation to 1,980 MW and add 1,400 MW of natural gas and 300 MW of solar by 2030 – a decarbonization of 54% of its generation assets in just 10 years. The bulk of the current coal capacity will be replaced by natural gas and renewable assets (mostly solar).

Figure 5.239 **Forecast for installed power (in MW) at Complexul Energetic Oltenia (2020-2030)**



Source: The 2020-2030 Development and decarbinisation plan of CE Oltenia

Natural gas

It is positioned to become the largest fuel in power generation over the next decade. There is a total of at least 3,000 MW worth of new projects announced/planned, such as:

- Romgaz CCGT at **Iernut** (430 MW);
- new 200 MW gas-fired block at **Craiova 2**, i.e.: construction of a combined cycle gas-fired high-efficiency cogeneration unit (CCGT) to supply heat to Craiova city and to economic operators (i.e.: Ford), which is to replace the current lignite-fired capacities of 2 x 150 MW;
- new 400 MW unit (CCGT) at **Turceni**, which will replace a current 300 MW lignite-fired capacity at Turceni (project of Complexul Energetic Oltenia);
- two new 400 MW units (CCGT) at **Ișalnița** which will replace unit 7 and 8 (two lignite-fired units of 315 MW each) - project of Complexul Energetic Oltenia;
- new CCGT at **Mintia** (400 MW), in the North-West (a Romgaz project);
- new unit of 70 MW in Midia (project of Rompetrol);
- a CCGT unit at Grozăvești (Elcen project);
- a CCGT unit at **Bucharest South**, of approx. 200 MWe and 200 MWt (Elcen project);
- a gas-fired cogeneration capacity at Progresu (Elcen project);
- upgrade of **Bucharest West** in order to extend its lifespan/implementation of a new combined cycle unit of approximately 186 MWe and 170 Gcal/h.
- CCGT at Halanga (RES, CCGT + hydrogen).

Renewables

The estimate for investments of €15-17 billion is based on a number of assumptions. In the last decade Romania added some 5 GW of new renewable capacity at a cost of €8 billion. Romania targets an additional 6.9 GW by 2030, which should cost up to €11 billion, assuming traditional RES areas (onshore wind and solar). If offshore wind is added into the mix (which is more expensive), this figure can be even higher (€20 billion). At the moment, Romania's wind capacity is situated exclusively onshore.

But the Black Sea in general is considered to hold significant potential for offshore wind: according to the World Bank, 453 GW of technical offshore wind potential – 269 GW for bottom-fixed and 166 GW for floating offshore wind. In addition, Europe published its Offshore Renewable Energy Strategy in November 2020. Banks are keen to finance offshore wind in Romania. Hidrolectrica, the state-owned hydro producer, already announced its plans to build 300-500 MW of offshore wind projects. There is currently no regulatory framework for offshore wind, however the Romanian Parliament is debating a draft Offshore Wind Bill. Furthermore, Romania's National Integrated Energy and Climate Plan (INECP) in its current version does not foresee any offshore wind development, but this can change in 2023 (next document update).

Offshore wind projects will require grid reinforcement in Dobrogea (already operated at capacity in this area), or investment in new power lines to allow the uptake of the new electricity produced offshore. The next decade is also likely to bring about the first electricity storage projects in Romania. Proposals for such projects have already been submitted in response to the call for projects conducted for the Modernization Fund (10d mechanism), under which some € 6-7 billion can be accessed specifically for RES, storage and grid modernization projects (including power lines). Therefore, the estimated investment of €15-17 billion in renewables by 2030 is the sum of the €11 billion (for traditional RES projects) plus an allowance of minimum €4 billion and maximum €6 billion for electricity storage and offshore wind development projects as well as any RES-related grid reinforcement costs.

It is important to note that all these are estimates. There are no guarantees as to which projects will be implemented eventually. Romania has a wish-list, but in the end a lot will depend on the financiers (IFIs, EIB, European Commission) who have a say in project selection (which projects can secure funding). And a lot will depend on timely project execution.

SERBIA

Serbia

Economic and Political Background

Serbia's GDP slid at a milder pace of 1.1% year-on-year in the final quarter of 2020, following the 1.4% contraction tallied in the third quarter. On a seasonally-adjusted quarter-on-quarter basis, economic growth waned markedly in Q4, slowing to 2.2% from the previous period's 7.2% increase. Taking the year as a whole, the economy shrank 2.5% in 2020, contrasting 2019's 4.2% expansion and marking the first contraction since 2014.

The fourth quarter's softer annual contraction largely came on the back of a rebound in the external sector. Exports of goods and services bounced back in Q4, growing 2.1% year-on-year (Q3: -8.5% y-o-y). In addition, imports of goods and services rebounded in Q4, growing 0.8% and contrasting Q3's 2.7% decline.

Meanwhile, on the domestic front, private consumption fell 2.7% in the fourth quarter - a sharper drop than the third quarter's 1.1% contraction - likely reflecting the tightening of restrictions amid a resurgence in Covid-19 cases. On the other hand, government spending bounced back, growing 4.6% in Q4 (Q3: -1.1% y-o-y), while fixed investment dropped at a milder pace of 4.1% in Q4 (Q3: -4.5% y-o-y).

Economic growth is forecast to return this year as activity rebounds amid the relaxation of restrictive measures. Moreover, the reopening of foreign economies will boost external demand. That said, the outlook is clouded by lingering downside risks amid uncertainty over the evolution of the pandemic, a rise in unemployment and the phasing out of some relief measures. IMF estimates that Serbia's GDP will expand by 5.5% in 2021, significantly higher than -2.5% in 2020.

The year 2020 was expected to bring further increase in Aleksandar Vučić's power after the parliamentary elections.

This was complicated by coronavirus pandemic, but with careful management, weakness of the opposition and some luck, achieved anyway. At the end of the previous year, Vučić looked forward to the third "victory over coronavirus" without parliamentary opposition and at least temporarily relieved from pressure over Kosovo issue.

Energy Policy

National Energy Policy

Serbia's economy is strongly impacted by market forces, but the state's influence remains significant in certain areas that require long-term approach and exhibit broad (socio-economic) implications.

In Serbia the state is still the key player in the energy sector. The national energy policy and development strategy of the Republic of Serbia are formulated at central government level and adopted by the National Assembly.

Legal commitments under the Energy Community Treaty, the EU accession process and the Paris Climate Agreement (2017) need to be converted into actions, within the transition roadmap and the further structural transformation of the energy sector.

All national goals, activities and measures in the energy sector are in line with the objectives of the Energy Strategy of Energy Community, which implies creating a competitive and integrated energy market, attracting investment in the energy sector and ensuring safe and sustainable energy supply. Serbia's coal-based energy sector is under pressure to adapt to new political priorities and the new decarbonized energy landscape.

In view of the three components of EU's energy policy, i.e. security of supply, competitiveness, and sustainability, Serbia as an EU accession country will have to harmonize its energy and climate policies.

The new upcoming obligation (2018) including the preparation of National Energy and Climate Plan (NECP) should cover the period from 2021 to 2030 with the intention of achieving agreed 2030 targets set by Energy Community. The NECP is currently under preparation and is planned to be submitted to the EnC by the end of 2021. All subsector strategies will have to merge in the NECP. EU Commission is expected to propose the 2030 targets for the Energy Community in the first half of 2021.

Improving energy efficiency and decarbonizing the Serbian energy system is a capital-intensive process that essentially involves the substitution of fossil fuels. From the transition perspective, natural gas can provide near-term benefits when replacing more polluting fuels. Scaling up the utilization of renewable energy sources is important not just for power, but for the heating and transport sectors also.

In general, Serbia faces a unique dual transition: transition towards decarbonized society and transition from centralized state-controlled systems to open and competitive markets.

Policies and policy measures in Serbia in general are defined by Laws and other documents, which in most cases include strategies and action plans. The main characteristic of the current Energy Law adopted in December 2014 (Official Gazette 145/2014) is the abolition of monopolies and the introduction of market competition in all energy activities and transposition as provided by the Third Energy Package.

National energy policy is elaborated in more detail through the Energy Sector Development Strategy for the period 2015-2025, with projection up to 2030, the Implementation Program of the Energy Development Strategy for the period 2017 to 2023 and the annual Energy Balance of the Republic of Serbia.

The Strategy is a document outlining the energy policy and energy sector development planning and it is adopted by the National Assembly for a period of at least 15 years. The Implementation Program establishes the conditions, manner, dynamics and measures to implement the Strategy for a period of up to six years.

The Ministry of Mining and Energy (MoME) is responsible for preparing the country's annual energy balance. Consequently, the Energy Balance defines the needs for energy and energy products, sources to provide the required quantities, and the required level of reserves. The Energy Balance is adopted by the government, not later than late December of the current year for the following year.

Serbian Governmental Institutions

The National Parliament adopts energy related legislation, approves Energy Sector Development Strategy and appoints the Council members of the Energy Agency of the Republic of Serbia (AERS).

The Government, as the top executive political body, determines conditions for supply and delivery of energy products (electricity, natural gas and oil), as well as intervention measures in the event of the major disturbances in the energy market. Government adopts the Energy Sector Development Strategy and secondary legislation, decides on launching tendering procedures for the construction of energy facilities (following proposals of the Ministry of Mining and Energy).

The Ministry of Mining and Energy (MoME) is responsible for state administration related to mining, energy, and energy balance of the Republic of Serbia, together with power, gas and oil industry development. The Ministry is in charge of formulating the country's energy policy, energy sector development strategy, energy related legislation and secondary legislation concerning security of supply, energy efficiency and utilisation of renewable energy sources. The Ministry monitors the implementation of the Strategy and development of legal framework within the energy sector. It is responsible for introducing energy-related legal norms of the EU and Energy Community into the legal system of the Republic of Serbia.

The Regulatory Authority - Energy Agency (AERS) is the regulatory authority established with the purpose of improving, directing and supervising the electricity and natural gas markets based on the principles of non-discrimination and efficient competition, by creating a stable regulatory framework, as well as ensuring high standards of service in energy supply. Agency adopts and monitors implementation of methodologies, technical and market rules, tariffs, certificates and prices for regulated market activities. Agency also plays an important role in the work of the Energy Community institutions and offers support to other institutions on national and international levels. In future the competences of AERS will have to be extended to include a complete set of regulatory powers and objectives foreseen under the Third Energy Package, particularly the right to carry out investigations, impose measures to promote competition and proper energy market functioning.

Local municipal authorities have competences in the field of heat, energy efficiency and renewable energy use. They cooperate directly with the citizens, and have a very important role in motivating and promoting rational energy use. They are in charge of energy planning and energy balance at the local level.

PE Serbian Electricity Transmission System and Market Operator (EMS), with main activities in electricity transmission, transmission system control and organisation of electricity market. PE EMS is 100% owned by the Republic of Serbia. In 2015, EMS established SEEPEX - Electricity Exchange in partnership with EPEX SPOT, France.

PE Electric Power Industry of Serbia (EPS), 100% owned by the Republic of Serbia performs activities of electricity generation, trade and supply of electricity, coal production, steam and hot water production, rivers and lakes hydropower utilisation. After the envisaged restructuring measures had been realised, PE EPS became a joint-stock company in 2020. In 2015, EPS established EPS Distribution with its main activity of electricity distribution and distribution system operation.

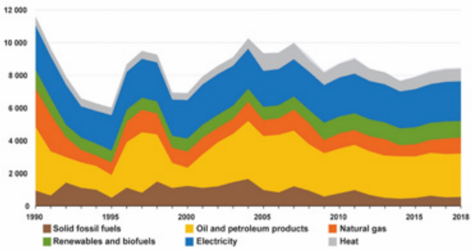
PE Srbijagas holds licenses for natural gas supply, public gas supply, distribution and storage. The transmission operators are the newly formed companies Srbijagas-Transportgas, Yugorosgas-Transport and Gastrans. The expected unbundling in market activities of Srbijagas is ongoing.

PE Transnafta is the public company established by the Government of the Republic of Serbia in 2005 for the purpose of carrying out pipeline transportation of crude oil and oil derivatives. The company is also licensed for trade and storage of oil and petrol derivatives.

Energy Demand and Supply

Today, Serbia faces serious challenges when it comes to harmonization of its Energy and Climate policy in a sustainable way.

Figure 5.243 **Serbia – Final energy Consumption 1990-2018 (ktoe)**



Source: Eurostat

Serbia has survived the last 30 years in very turbulent circumstances. Civil war and partition of the former Yugoslavia, economic blockade (1992-2002), NATO bombing (1999) and the perennial problem with the province of Kosovo and Metohija.

Figure 5.243 shows declines and fluctuations in energy consumption that result from these historical circumstances. Serbia's economy and industry have not yet reached the 1990 development level.

Security of energy and fuel supply to Serbia's energy market is reliable and still optimal owning to the considerable reserves of domestic coal and some reserves of oil and natural gas. Coal is and will continue for some time to be a relevant energy source in Serbia's primary energy supply

Table 5.199 **Serbia - Primary Energy Consumption (Mtoe)**

Primary Energy Consumption	2015	2016	2017	2018
GROSS INLAND CONSUMPTION - TPES	15.054	15.668	16.023	15.802

Primary energy consumption of the Republic of Serbia in 2018 was 15.802 million toe, while its structure is presented in Table 5.202. Over

90% of the necessary coal amounts, whose share in the primary energy consumption is 48%, are secured from domestic sources. Coal consumption is dominantly connected with energy generation (about 86%), where thermal power plants have the highest share.

A race is underway among coal, natural gas and renewables to provide power and heat to Serbia's fast-growing economy. Coal share decreases, natural gas consumption increases and renewables have a greater share in the energy mix than before.Considering the depleted natural gas and crude oil deposits in Serbia, the trend of increased import dependence continues. In 2018 import dependency has already reached 77% for oil and 82% for natural gas.

The total renewable energy sources potentia which is technically available in the Republic of Serbia, is estimated to 5,65 Mtoe. 1,121 Mtoe of biomass and 0,979 Mtoe of hydropower of this potential is already utilized.

Biomass potential is available in the entire territory of the Republic of Serbia. Wood biomass is mostly located in the area of central Serbia, and agricultural biomass in the area of Vojvodina. The level of wood biomass use is relatively high (70%) while agricultural biomass is used very little (about 2%).

Energy Market

Oil and Petroleum products

Ever since 2009, NIS has been the only company in the Republic of Serbia engaged in crude oil and natural gas research, exploration and production. Oil production in the Republic of Serbia is carried out in 63 oil fields with 666 wells by various extraction methods.Oil processing is performed in two oil refineries in Pancevo (4.8 million t/year) and Novi Sad (2.6 million t/year) producing a wide range of petroleum products. The plant in Novi Sad is not used at present and, so the current processing capacity is 4.8 million tones of crude oil a year.

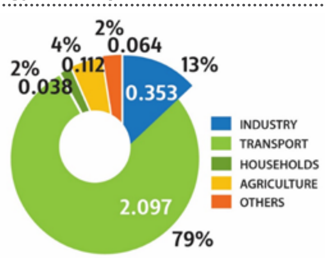
In 2018, Serbia's crude oil production was 0.926 million tons, while imports of crude oil and oil derivatives were around 2.69 mil. tons. The total consumption of crude oil and semi-finished products from domestic production, imports and supplies in 2018 in Serbia was about 3.6 mil. tons and the overall final consumption of petroleum products was 2.66 Mtoe. With regard to motor fuels, unleaded super gasoline accounted for 17.9%, gas oils-euro diesel for 74.3%, and LPG for 7.8%. In the Republic of Serbia, there are about 2.5 million registered vehicles, of which only 200 are electric vehicles, so it can be said that they do not affect the total consumption of motor fuels so far.

Crude oil imports are fully liberalized and the prices are set by the market. The import and trade of crude oil and petroleum products, including biofuels and compressed natural gas and storage, is undertaken by a large number of economic entities.

At the end of 2019 there were 25 licenses issued for crude oil trading and petroleum products storage, 52 for wholesale of crude oil and petroleum products and 461 for petroleum products retail trade. The retail trade of petroleum products in the territory of the Republic of Serbia is performed through a well developed and extensive trade network of about 1500 retail facilities.

Figure 5.249 **Serbia – Oil and Petroleum products final energy consumption 2018 (Mtoe)**



Source: SORS

PE Transnafta is the public company established by the government of the Republic of Serbia in 2005 for the purpose of carrying out pipeline transportation of crude oil and oil derivatives.

The company is also licensed for trade and storage of petroleum derivatives.

Crude oil transport to Pancevo Refinery is operated via Janaf, through the former Yugoslav oil pipeline infrastructure of 622 km from Adriatic Sea to Pancevo. Transnafta performs the oil transport through Serbian territory via a pipeline of 155 km stretching from the Danube on the border with Croatia to Pancevo. Associated pipeline infrastructure consists of a terminal in Novi Sad with four crude oil tanks of 10.000 m³ each. The average annual amount of transported oil is about 2.5 million tons/year (domestic and imported oil).

The transportation of oil derivatives in the Republic of Serbia is carried out by rail, ships and roads. Oil transport by oil pipelines and oil derivatives transport via product lines, are regulated activities of general interest separate from other energy-related activities and are performed by Transnafta under regulated prices. Pipeline transportation is a more economical, efficient and environmentally friendly mode of transport.

There are plans for a project for the construction of the Product Pipeline System connecting the Oil Refinery in Pancevo with the existing storage tanks in Smederevo and Novi Sad. The first section to Smederevo (27 km, with crossing the Danube) was scheduled to be put in operation in late 2020. Project realization after 2020 depends on the fuels' consumption trend and market demands.

A long-term plan for Serbian Product Pipeline System envisages connection of Pancevo to Sombor, in the north, and with the City of Nis, in the south with a total length of 402 km. Crude oil and petroleum products storage has a significant role in ensuring security in the country's energy supply, especially in case of market disruption caused by shortages usually followed by energy prices increase.

By EU Directive 2009/119/EC member states are obliged to maintain emergency stocks of crude oil and petroleum products in quantity of 90 days of average daily net imports or 61 days of average daily inland consumption. Signing the Agreement on the Energy Community of South-East Europe and gaining the EU membership candidate status, and in accordance with the above Directive, the Republic of Serbia is obliged to maintain conditions for keeping the required amount of crude oil and petroleum products that amounted to 1 million tons in 2020.

According to a statement from the Ministry of Mining and Energy, Serbia currently maintains reserves for 18 days of supply (2018).

Map 5.64 **JANAF oil pipeline route through Serbia and Croatia**

Source: Updated data from Energy Sector Development Strategy of Republic of Serbia for the period by 2025

NIS JSC is the dominant market player in Serbia dealing in oil, oil derivatives and natural gas exploration, production, processing and sales. Vertically integrated, it has been in the stock exchange since 2010. It is controlled by the Russian company "Gasprom Njeft" with a share slightly higher than 56%, by the Republic of Serbia with slightly less than 30%, while around 14% is owned by a great number of small shareholders through the Exchange.

The majority of NIS oil fields are located in Serbian territory, in the province of Vojvodina. However, it has business operations both in Serbia and abroad. In 2011, NIS started to expand its business to south-east Europe: Bosnia and Herzegovina, Romania and Hungary.

The company owns and operates oil refineries in Pancevo (annual capacity 4.8 million tons of crude oil) and Novi Sad (annual capacity 2.6 million tons of crude oil), and a natural gas refinery in Elemir. NIS refining complex produces an entire range of petroleum products - from motor gasoline and diesel fuel to mechanical lube oils and feedstock for the petrochemical industry, heavy fuel oil, road and industrial bitumen, etc. NIS accounts for 80% of the Serbian refined products market. The company sells a total of some 2.5 million tons of refined products annually.

In the retail market of motor fuels and other types of fuels, a considerable share is also held by Lukoil, OMV, MOL Serbia, EKO-Serbia, Knez Petrol, Petrol and smaller independent retail operators such as Europetrol, System Mihajlović, Art Petrol, AVIA, etc.Key development projects for NIS in the period 2018 - 2020 were the completion of the „Bottom-of-the-barrel" project at the Pančevo Refinery and the construction of a combined-cycle power plant, also in the town of Pančevo (140MW).

Directive 2009/28/EC, which refers to the required content of biofuels in motor fuels, in order to reduce greenhouse gas emissions, has not yet been implemented in domestic legislation. According to the Renewable Energy Action Plan it is assumed that this obligation would reach 10% of the share of biofuels in motor fuels by 2020, but the share of biofuels in the overall oil products market in 2016 was still negligible. Only one energy company, Biogor Oil doo from Sukova, has been licensed for the activity of biofuel production and bio-liquid production. The same company, with NIS, is only licensed for the energy activity of blending biofuels with fuels of petroleum origin.

Natural Gas

Natural gas is the third most used primary energy source in Serbia, after coal and oil. Gross domestic consumption in 2018 amounted to 2,667 bcm. Domestic production covered 18% of gas demand while the remaining amounts were secured by imports from the Russian Federation under a long-term contract.

At present Serbia has only two interconnections, the one at the border between Hungary and Serbia (entry point) and the other at the border of Serbia and Bosnia and Herzegovina (exit point). Serbia's total geological reserves of natural gas are small and can be estimated at 50 Mtoe.

Natural gas exploration and production in Serbia is performed exclusively by the Petroleum Industry of Serbia (NIS). The transmission and transmission system operation are performed by natural gas transmission system operators: Srbijagas-Transportgas and Yugorosgaz-Transport. The length of the Srbijagas-Transportgas transmission system amounted to 2,339 km (95%) in north and central Serbia, while the length of the Yugorosgaz-Transport transmission system is 125 km (5%) in southern Serbia. Natural gas markets in Serbia are still under development.

Source: SORS

Natural gas imports from the Russian Federation under long-term and other contracts amounted to 2,198 bcm in 2018, and all imported quantities were delivered at the Serbian – Hungarian border.

Serbia is intensively working on interconnections with neighbouring countries, which will enable gas supplies from new sources. The interconnection with Bulgaria is crucial through the construction of the Nis-Dimitrovgrad-Sofia gas pipeline.

The Bulgaria-Serbia Interconnection (IBS), expected to be completed by the mid 2022 at the latest, along with the Greece-Bulgaria Interconnection (IGB), connecting Serbia to the Southern Gas Corridor and opening up opportunities for the future supply of Caspian gas via the TANAP and TAP pipelines, as well as the regional LNG terminals. In addition to the TANAP and TAP pipelines, whose capacity is limited and already "sold out", the Turkish Stream is a realistically promising option. Under the Gastrans management, Serbia has built a 403 m long line section of the main interconnector gas pipeline from the border with Bulgaria (Zajecar) to the border with Hungary (Horgos), which is a continuation of the TurkStream pipeline.

The Balkan Stream project is of strategic importance for Serbia and provides the backbone of many new energy projects. The construction work is finished on both sides of the border. The earliest date for completion and commissioning would seem to be in the first half of 2021. This represents a new supply and transit route (with capacity of 12,87 bcm/y) of Russian gas primarily, thus increasing Serbia's energy security and will enable further reindustrialization of the country. Furthermore, there are plans for new interconnections between Serbia and Romania (Mokrin – Arad) and between Serbia and Croatia (Futog-Sotin).

Table 5.209 **Serbia - Technical characteristics of the natural gas transmission system – 2018**

Transmission and Storage

Under the agreement of the governments of Romania, Bulgaria, Greece and Serbia, the concept of the Balkan Gas Hub provides for the supply of natural gas from different sources: the Black Sea (Romania and Bulgaria), the Southern Gas Corridor (Caspian region, Middle East and Eastern Mediterranean), LNG terminals in Greece and Turkey and Russian gas via Turkish stream. The shortest route to the Central European gas market is passing through Serbia. Therefore, Serbia has a key role to play in ensuring the transit of natural gas to Central Europe after its entry into the Balkan Gas Hub.

The Bulgaria (Sofia)–Serbia (Nis) Interconnector is one of the priority projects between the two countries. Initially, the interconnector pipeline is expected to deliver 1,8 bcm of natural gas annually. The Nis-Sofia interconnector has a length of 171 km and is planned to be operational in mid-2022. The European Union, through its grants, is contributing to the financing of the project, and 49.6 mill. € has been committed by Serbia. The overall development of the Nis-Sofia transport system, which will provide the full capacity of reverse transmission of natural gas (2,7 bcm from Serbia to Bulgaria and 3,2 bcm from Bulgaria to Serbia), requires additional 208 mill. €.

In June 2017, a Road Map was signed between the Ministry of Mining and Energy and Gazprom for the implementation of the project Balkan Stream, for the construction of the main transport gas pipeline in the territory of the Republic of Serbia, from the border with the Republic of Bulgaria (Zajecar) to the border with Hungary (Horgos).

A joint project company, Gastrans LLC Novi Sad is the project developer and 95% of activity has already been done in Serbia. The "Balkan Stream" gas pipeline in Serbia is just over 400 kilometres long, the projected pressure is 75 bar, the pipe diameter is 1,220 millimetres and annual gas transportation capacity is 12,87 bcm. This pipeline is planned to be operational in the first half of 2021. Implementation of the Bulgaria-Serbia-Hungary main gas pipeline project will significantly increase the level of energy security both in Serbia and the region. On 21 February 2020, the Serbian Energy Agency Council adopted a Decision issuing a certificate to Gastrans LLC as an independent natural gas transmission operator.

Srbijagas-Transportgas is creating preconditions for the connection to neighbouring countries network. In addition to the Nis-Sofia interconnector there are plans to build interconnections with Romania (Mokrin-Arad - 1 bcm) and Croatia (Futog – Sotin -1,5 bcm). Banatski Dvor Underground Gas Storage (UGS) is located at a depleted gas deposit whose capacity used to be 3,3 billion cubic meters of natural gas. There is currently 450 million cubic meters of available capacity while the maximum productivity in the withdrawal process amounts to 5 million m³/day. After phase two of construction, the storage will have increased to 800 million cubic meters of capacity. This storage is connected to the natural gas system through two gas pipelines.

During 2018, more natural gas was taken out of the storage than delivered to the facility. At the beginning of 2018, there was 404 million m³ of commercial gas. From the transportation system, 273 million m³ were delivered to the storage, of which 3 million m³ was consumed by the facility's own needs, while the remaining

270 million m³ of gas was injected for commercial purposes. Users have taken over 299 million m³ from the storage, also delivered to the transport system. At the end of 2018, there was 375 million m³ of commercial gas inside the storage. There are plans to build a new underground facility at Banatski Itebej, with a capacity similar to the existing Banatski Dvor as well as a smaller Tilva storage. Srbijagas and Yugorosgaz have undergone the initial unbundling of transmission activities. The two newly established transmission system operators are the Transportgas Serbia LLC and Yugorosgaz -Transport LLC companies.

Map 5.65 **Serbia – Current natural gas transmission network - 2019**

Source: Gastrans

Natural Gas Market

Natural gas market participants include producers (NIS JSC), suppliers (66 companies), public suppliers (33 companies), transmission system operators Srbijagas-Transportgas and Yugorosgaz-Transport, distribution system operators (33 active companies) and one storage operator UGS Banatski Dvor. Serbia currently consumes about two and a half billion cubic meters of gas annually. Industrial production is beginning to grow and Serbia will certainly need more gas. In the past five years, Serbia's natural gas consumption increased by about 5% per year, while the domestic production has fallen significantly. In the upcoming period, it is expected that the domestic production will continue to decline.

Given the increase in industrial consumption, the planned construction of several CHP installations and expanding the country's natural gas transportation and distribution network, it is estimated that annual consumption in 2030 will be about 4 bcm/y.

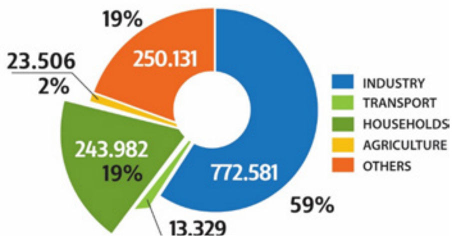
Under the Energy Law, the following regulated energy activities are of general interest:

- natural gas transmission and natural gas transmission system management,
- natural gas storage and natural gas storage facility management,
- natural gas distribution and natural gas distribution system management and
- public supply of natural gas.

Serbia's Energy Agency (AERS) is the competent body regulating the natural gas price for public supply, determining the natural gas transmission and distribution system access price and the natural gas storage access price. In order to ensure supply security of end customers, it is stipulated that households and small customers whose facilities are connected to the natural gas distribution system are entitled to public supply at regulated prices, if they opt not to choose another supplier. Small natural gas consumers are the final customers whose annual consumption of natural gas is less than 100,000 m³.

The government of Serbia appointed Srbijagas as the supplier of public natural gas suppliers under public tendering. The total distribution network length at the end of 2018 was 18.422 km. The share of the Srbijagas distribution network in total distribution network length is 52%. At the end of 2018, there were over 276.581 delivery points of which 64 inside the transport and 276.517 inside the distribution network. Of these, 262.814 or 95% are households, which is only roughly 10% of all households in Serbia. Average annual consumption of natural gas per connected household in 2018 was 1009 m³.

Figure 5.251 **Serbia - Final natural gas consumption (1,303.529 bcm) by sector - 2018 (mcm, %)**



Source: SORS

A bilateral market is functioning in the natural gas sector. In the wholesale natural gas market, buying and selling takes place directly between market participants. The wholesale natural gas market in 2018 was based on trade between natural gas suppliers and between natural gas suppliers and producers. In 2018, three suppliers (Srbijagas, King gas and Cestor Veks) and one producer, NIS, participated in the wholesale market. The average wholesale price at which suppliers sold natural gas to other suppliers in 2018 was 34.03 RSD/m³ (~0.29 €/m³).

At the end of 2018, the business of distribution and distribution system operation was performed by 32 licensed distribution system operators. In addition to distribution system operators, Srbijagas and Yugorosgaz, distribution and distribution system operation is performed by 30 other companies, most of which are owned by municipalities and cities, some are mixed and partly privately owned. The average weighted approved distribution system access price for all distribution networks in Serbia as of 31 December 2018 was 4.35 RSD/m³. In the retail bilateral market supply was carried out at both unregulated and regulated prices. Since 2018 all customers, except households and small customers, had to buy natural gas in the free market. The Serbian government appointed Srbijagas as a supplier supplying public suppliers with natural gas under the same conditions and price. During 2018, a total of 1.881 million m3 was delivered to buyers in the free market, while 321 million m³ was delivered to buyers under regulated prices.

The average weighted retail price realized in the free market in 2018, including transportation and distribution system use costs, was 35.26 RSD/m³ (~0,30 €/m³), while the realized weighted average retail price in the regulated market was 34.82 RSD/m³ (~0,29 €/m³).

The greatest share of natural gas, over 1.778 million m³ (81%) of the total amount was sold to final customers by Srbijagas in 2018. The second greatest share was sold by the DP Novi Sad Gas with 72 million m³, or about 3,3%, while Yugorosgaz came third with 51 million m³ or 2,4% of the total amount sold in 2018. Individual share of the remaining suppliers in the total amount is some 2%.The 2025-2030 Energy Sector Development Strategy considers two natural gas consumption scenarios: reference scenario and energy efficiency measures implementation scenario. Both scenarios foresee an increase of gas consumption, both for transformation input (CHP gas facilities, increase of gas share in district heating plants and auto producers) and for final consumption. Around 5 million, or 70% of Serbia's population, lives in areas with a developed transportation network, with further natural gas system expansion and consumption growth potential. In the upcoming period, natural gas consumption will be governed by various energy sector factors (natural gas price, infrastructure development, prices of other energy sources, etc.), general economic and social development factors (GDP growth, purchasing power of the population, implementation of environmental regulations, demographic indicators, structure of industrial production, etc.). Further increase of import dependency for natural gas can be expected, from 82% in 2018 to around 90% by 2025.

Solid Fossil Fuels - Coal

Coal represents the largest share in Serbia's Total Primary Energy Supply (TPES) (with a share of 48%) followed by Oil (24%), Natural gas (15%) and Renewables (13%). Coal is the most significant domestic fuel, and the estimates suggest that existing deposits should be sufficient even after 2050. The coal sector includes coal extraction and processing. Coal is mined in surface and underground mines and in one underwater mine. However, the domestic coal structure is dominated by low-quality lignite.

In 2018, 7.263 Mtoe (38,645 million tons) were consumed in transformation processes, of which 6.273 Mtoe (36,517 million tons) or 86% in thermal power plants, while the remaining 14% by industrial power plants, district heating plants, blast furnaces and coal processing.

Almost 98% of the total domestic coal production comes from surface mining (37 million tons in 2018) while the remaining amount of 0,660 Mt comes from underground and underwater coal mines. Since the domestic production mainly yields low-quality lignite and covering some 95% of the total coal demand, roughly 5 - 10% are imported. Coal imports include different types of coal, primarily coke for metallurgy and high-caloric coal for industrial use, followed by anthracite and brown coal for retail consumers.

Source: SORS - Statistical Office of the Republic of Serbia

Coal mining and processing in Serbia takes place in:

- Surface coal mining in two major mines in Kolubara and Kostolac operated by PE EPS. Production of low-quality lignite in 2018 was: Kolubara 28,4 Mt and Kostolac 8,6 Mt

- Underground mining in PE Resavica – nine underground mining facilities producing high quality hard and brown coal with annual production of about 0,48 Mt.
- Underwater mining of lignite in Kovin with an average annual production of 0,22 Mt.

One of the problems in supplying coal from surface mines is the uniformity of coal quality in order to achieve savings, as well as to reduce specific coal consumption by the Nikola Tesla Thermal Power Plants (TENT). Kolubara coal processing plant also produces some 0,78 Mt of dry lignite.

Table 5.213 **Serbia - Coal Production structure by EPS subsidiaries in 2018 (t)**

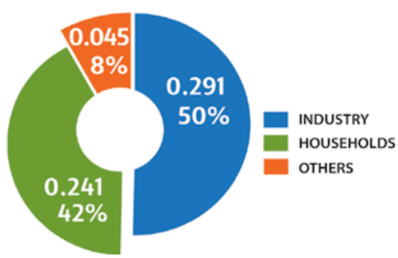
Figure 5.254 **Serbia - Coal – Final energy consumption by sector 2018 – 0.578 Mtoe**



Source: SORS

Final coal consumption in 2018 amounted to 0.583 Mtoe, of which 0.005 Mtoe and 0.578 Mtoe for non-energy and energy purposes, respectively. The share of industry in the final consumption mix is 59%. It is followed by households 19% and other sectors with 22%.

Map 5.66 **Serbia - Mining basins of Serbia**

Source: EPS

Serbia's most significant coal deposits consist of low-quality lignite. Geological reserves of lignite compared to the geological reserves of all coal types in Serbia cover 97%. Total coal reserves available for mining are substantial and represent a realistic basis for further long-term development of the energy sector in general and particularly for electricity generation.

Table 5.214 **Serbia - Coal geological reserves (Mtoe)**

Source: EPS

The structure of Serbia's fossil fuels reserves is presented in Table 5.215. Reserves of higher quality energy products, such as oil and gas are negligible and make less than 1% of geological reserves with a high exploration level, while the remaining 99% of energy reserves include various types of coal, with lignite having the highest share, over 95% in the investigated reserves.

Table 5.216 **Serbia - Geological reserves and resources of fossil fuel (Mtoe)**

Resources (Mtoe)	Proven and probable geological reserves	Total geological reserves and resources
Hard coal	2.77	4.02
Brown coal	37.7	45.17
Brown-lignite coal	134.25	193
Lignite	1.583 (780*)	3.698
Oil	10.14	50
Natural gas	3.37	50
Oil shale	-	398**

*Without Kosovo and Metohija **Kerogen - organic part of oil shale Source: EPS

Estimated reserves of oil shale in the Republic of Serbia are about 4,8 billion tons. They may be found in few locations, but a higher degree of exploration has been achieved at the Aleksinac reservoir with the deposit of around 2 billion tons. There is some interest in oil shale mining.

However, its exploitation depends on the prevailing crude oil price. Oil shale can be effectively used to produce synthetic oil (by extraction), which can be used as fuel or upgraded by refining to petroleum products, while the residual part could be used in electricity generation. From an environmental point of view, the project is acceptable since there is no need for extracted oil shale disposal.

Strategic mid-term coal sector actions and measures include:

- More intensive exploration of coal deposits across the entire area of Republic of Serbia.
- Opening of replacement capacities for existing open pit mines close to depletion and opening of open pit mines to supply new thermal power plants.
- Optimization and concentration of underground coal production.
- Introduction of coal quality management system.
- Harmonization of national legal framework with EU and Energy Community legislation in the coal sector.

Electricity

The current structure of the electricity sector in Serbia was established in 2005 after the unbundling and internal reorganisation of the vertically integrated public company Electric Power Industry of Serbia (PE EPS). Transmission, transmission system operation and market operation are performed by EMS (TSO), while EPS is the company dominating the generation, distribution, supply, public supply and supply of the last resort. Both companies EMS and EPS are 100% owned by the Republic of Serbia. In 2016, EPS established EPS Distribution, a distribution system operator (DSO). Although the legal unbundling of EPS Distribution was finalized the functional unbundling has not yet been completed. In partnership with EPEX SPOT, France, EMS established an organised day-ahead electricity market (exchange) SEEPEX.

Table 5.217 **Serbia - Electricity balance & Final electricity consumption (TWh)**

Electricity - TWh	2015	2016	2017	2018

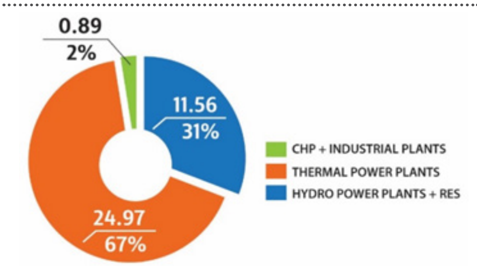
Source: SORS, Statistical office of Republic of Serbia.

Conventional thermal power generation has the largest share (close to 70%) in the generation mix, followed by hydropower generation (some 30%). Serbia is almost self-sufficient, with minor seasonal deviations of shortages and surpluses.

Figure 5.255 **Serbia - Gross electricity generation in 2018 (TWh, %)**



Source: SORS

Total electricity generation in 2018 amounted to 37.42 TWh, while the gross electricity consumption was at the level of 32.58 TWh.

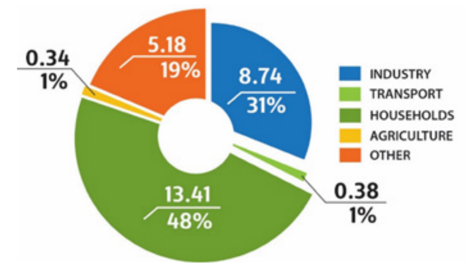
The largest share of generation was achieved by thermal power plants (67%) and hydropower plants plus other RES (31%). The small independent electricity producers generated some 0.6 TWh. Electricity imports and exports were 6.40 TWh and 6.28 TWh, respectively.

In addition to EPS, there are 66 licensed free-market suppliers with main activities in the area of cross-border trade, mainly for transit through Serbia, which is dominant due to the central geographic position of Serbia's electricity system with 8 borders. In the year 2018, electricity transit through Serbia reached the level of 12 TWh.

Electricity demand has shown little increase over the past several years. Annual peaks are still achieved in winter partly due to the cold climate and extensive use of electricity for heating. In recent years, there was a somewhat larger increase in the summer peak loads. Maximum average hourly load of the system amounted to 5,805 MW and it was achieved on 28 February 2018 at 8 p.m.

Figure 5.256 shows the structure of Serbia's final electricity consumption in 2018. The largest share was consumed by households (48%) and industry (31%). The remaining 19% of the final consumption was used by public and commercial users.

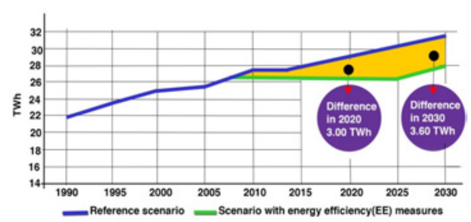
Figure 5.256 **Serbia - Final electricity consumption by sector 2018 (TWh, %)**



Source: SORS

In 2015, the Serbian government adopted the Draft Energy Sector Development Strategy covering the period up to 2025 with the forecasted annual average growth in electricity consumption until 2025 of less than 1%. These assumptions took into account the growth of the industrial sector as well as energy efficiency measures in all consumption sectors. Energy efficiency measures can save some 3TWh of the final consumed electricity in 2025 based on international benchmarks.

Figure 5.257 **Serbia - Final electricity consumption projections up to 2030 (TWh)**



Source: Energy Sector Development Strategy of the Republic Serbia 2025-2030

Generation Capacities

Serbia's electricity generation capacities comprise of thermal power plants (TPP), cogeneration power plants (CHP), large and small hydro power plants (HPP), industrial power plants and some independently owned plants using renewable energy sources (solar, wind, biomass and biogas).

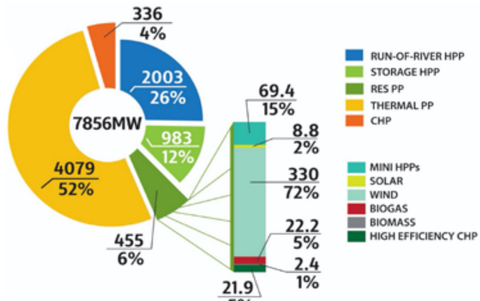
Figure 5.259 **Serbia - Total installed generation capacities structure in 2019 (MW, %)**

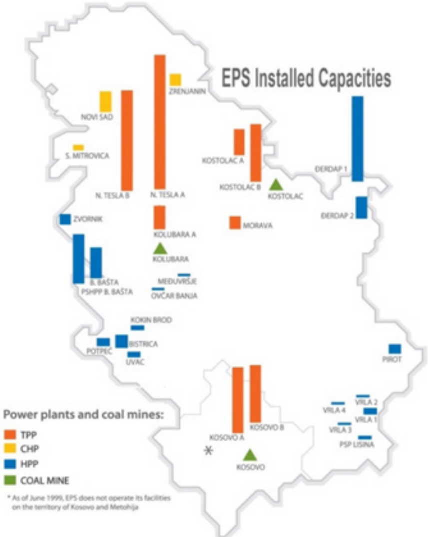


Source: MoME, EPS

Considering the age (over 25 years) and efficiency of existing generation capacities and the fact that some of them will be decommissioned, it is necessary to build new capacities. It is planned to build some coal-fired thermal power plants, a number of natural gas-fired CHPs, as well as to add several facilities fuelled by renewable energy sources (wind and hydro). Up to 2028 it is expected to add almost 1000 MW of wind capacity, mostly operated by independent power producers. Rehabilitation and revitalization of existing major power plants (TPP Nikola Tesla, HPPs Djerdap, Zvornik, Potpec etc.) will secure additional capacity for power generation. Other electricity generation projects preferably dedicated to utilising renewable energy sources are covered by the NREAP (National Renewable Energy Action Plan) adopted in 2013.

During the same period, 2020-2030, due to obligations stemming from the Energy Community Treaty, Serbia has to harmonize its electricity consumption and generation to meet the targets in energy efficiency, RES share in gross final consumption, limited pollutant emissions from large combustion plants and expected new climate targets. Under the Paris Climate Agreement, Serbia has committed to reduce its GHG emissions by 9.8% by 2030 compared to 1990 levels, however, it still does not have to reduce its GHG emissions under the Energy Community Treaty. Throughout the EU accession process, Serbia's electricity sector will face mandatory and financially challenging CO_2 emission costs by implementing the EU Emissions Trading Scheme. Currently, the share of electricity generation in Serbia's total CO_2 emissions is around 50%.

Map 5.67 **Serbia - EPS - Installed electricity generation capacities**



Source: EPS

In January 2020, the Serbian government adopted the National Plan for the Reduction of the Main Pollutant Emissions from Old Large Combustion Plants (NERP) with the aim of harmonizing emissions from large combustion plants with the limits set out in the EU Industrial Emission Directive by the end of December 2027. Application of the Large Combustion Plants Directive and Industrial Emission Directive requires significant investments into modernisation and environmental improvements. Under EPS estimates, the required amount is close to 1 billion €.

Table 5.221 **Serbia - Potential new build projects of the electricity sector**

Transmission Infrastructure

Serbia's transmission system, without Kosovo and Metohija (K&M) operated by EMS, comprises of 38 substations of 400/x, 220/x and 110/x kV with installed capacity of 15,706 MVA. There are 449 high voltage lines of 400, 220 and 110 kV with total length of 9453 km. EMS transmission system is connected with the neighbouring power systems via 22 interconnection overhead lines of 400, 220 and 110 kV.

Table 5.222 **Serbia - EMS transmission system in 2018 (without K&M)**

Transmission system elements	Number of lines	Length km
400 kV	36	1.766
220 kV	46	1.845
110 kV	367	5.842
Total	**449**	**9,453**

Source: EMS, 2019-2028 Transmission System Development Plan

The Transmission Network Code governing technical transmission aspects and relations between EMS and system users was adopted for the first time in 2008. During 2011, 2013 and 2017 there were a number of amendments aligning it with the Market Code. In 2016, PE EMS was corporatized and it functions as a closed joint stock company, EMS JSC.

In 2018, by applying the ruling charges, average transmission use-of-system charge amounted to 0.49 RSD/kWh (~4 €/MWh) which is one of the lowest charges in Europe. Electricity losses of Serbia's transmission system amounted to 868 GWh in 2018, which represents 2.13% of electricity withdrawn into the transmission system. The loss reduction trend continued.

In cooperation with neighbouring transmission system operators, EMS is responsible for the allocation of rights to use available cross-border transmission capacities on interconnection lines of the Serbian power system. The joint explicit auctions for 100% of capacity allocations are in use on the borders with Hungary (2011), Romania (2013) Bulgaria and Croatia (2014), Bosnia & Herzegovina (2015) and North Macedonia (2017) while on the borders with Albania and Montenegro, there are the 50:50% rights for both neighbouring operators. In 2018, EMS generated revenue from capacity allocation amounting to 25 mill. €. Transmission system operator - EMS, as an ENTSO-E member (European Network of Transmission System Operators for Electricity), is required each year to update the national Ten-Year Network Development Plan (TYNDP), aligned with the Pan-European TYNDP. EMS is already participating in activities aimed at strengthening the Trans Balkan and North Continental South East (CSE) Power Corridors.

A group of projects is dedicated in strengthening internal transmission capacities (by replacing obsolete 220 kV network) and reinforcing the transmission capacity of busy international corridors (North – South, North-East to South-West) up to 2028:

1. New interconnection transmission lines between Serbia and Romania (double 400 kV transmission lines) Resica (Romania) - Pancevo (Serbia) and Porțile de Fier - Djerdap 1.
2. New double 400 kV interconnection between Serbia, Montenegro and Bosnia and Herzegovina.
3. New 400 kV interconnection between Serbia and Croatia.
4. New 400 kV interconnection between Serbia and Bulgaria.
5. Upgrade of the West Serbia's network to a voltage level of 400 kV (400 kV transmission lines Kragujevac - Kraljevo and Obrenovac - Bajina Basta).

Distribution Infrastucture

In July 2015, as a continuation of restructuring and corporate reform the incumbent company – EPS, established EPS Distribution having as a main activity electricity distribution and distribution system operation (DSO). The legal unbundling of the EPS Distribution was finalized, however, functional unbundling has not been completed yet.

By the end of 2020, the DSO was obliged by Law to take over metering devices, switchboards, connection lines, installation and equipment in the switchboard and other devices within the connection in the facilities of existing customers or producers since these devices and equipment are part of the distribution system. Strategic goals in the field of electricity distribution are to increase supply reliability levels, reduce electricity losses and optimize distribution network use.

The primary target of distribution system operator is to improve the measurement system of Medium Voltage (MV) and Low Voltage (LV) customers, those with active and reactive energy and monthly maximum power. Smart grids and measurement systems will enable high reliability and quality levels of delivered electricity. They will stimulate better consumption management and a more dynamic electricity market, as well as considerable reduction of technical and commercial losses. There is expectation that 3 million meters will be replaced by 2030.

Distribution system (without Kosovo and Metohija) covers around 36,000 substations with the total installed capacity of around 30,000 MVA and more than 160,000 km of distribution lines, with voltage levels of 110, 35, 20, 10 and 0.4 kV. Distribution Network Code has been in force since early 2010. The new version was approved by the regulator, the Energy Agency of the Republic of Serbia in late 2017.

The total number of electricity metering points for customers in Serbia (without Kosovo and Metohija) in late 2018 was 3.651.169, while the total number of customers was 3.507.133.In 2018, the average distribution use-of system charge for all customers amounted to 2.95 RSD/kWh (~2.5 c€/kWh). Today, the average monthly consumption per household in Serbia is 345 kWh.

Electricity delivered to customers over the distribution system in 2018 was almost fully taken over from the transmission system, nonetheless, considering the growth of distributed generation (mostly RES connected to the distribution system), some 8 GWh of electricity was supplied from the distribution system to the transmission system.

The core distribution network problem are high losses primarily caused by unauthorised connections, theft and long-term network and metering devices underinvestment. Distribution losses amounted to 3.66 TWh, or 12.2% of the electricity supplied to the distribution system in 2018. Designated future electricity distribution projects include improving metering infrastructure, distribution network automation, obsolete SS 110/X kV reconstruction project, together with the new SS 110/X kV construction project. The total investment value of these four projects is around 277 mill €.

Electricity Market

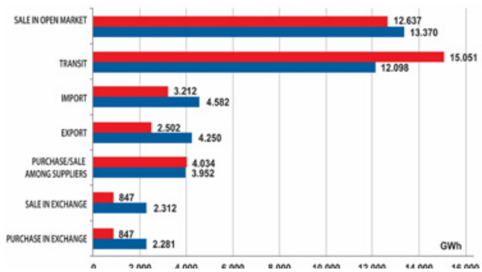
Electricity market in Serbia includes bilateral electricity market, balanced electricity market and organized electricity market. Main players are producers, wholesale and retail suppliers, customers, TSO and DSO, market operator and power exchange.

Purchase and sales of electricity are organized on the bilateral market directly between market players. On the wholesale bilateral market, the players traded electricity under open market prices, while on the retail sale side there are two groups of customers.

The first one includes customers supplied under open market prices (such as industrial customers), while the second one includes households and small customers supplied by the Public Supplier (EPS Supply) under regulated prices. After the Energy Law was adopted in December 2014, as of 1 January 2015 all households and small customers were able to freely choose their electricity supplier or remain a customer of the Public Supplier. EPS daughter company - EPS Supply - was appointed by the Energy Agency in 2013 as the official public supplier and a supplier of last resort. Coexistence of unregulated and regulated segments of the domestic electricity market operating under entirely different conditions is still a status quo in Serbia. However, it is only a matter of time when the low priced regulated electricity market (low retail prices for obvious socio-political reasons) will become open in the sense of most EU countries.

In 2018 there were 68 electricity market players entitled to nominate operational plans based on a relevant contract signed with EMS (mostly dealing with cross-border exchange), while there were only 18 supplying customers in the open market.

Figure 5.260 **Serbia - Electricity quantities by suppliers' activities in 2017 and 2018 (GWh)**



Sources: IEA, Eurostat, WB, SORS Statistical office RS, compiled by AERS

EPS was still the dominant supplier in the open market with 96,4% of the total electricity quantities sold to final customers in the open market and with 98,3% of the total final consumption.

Achieved average annual electricity price in 2018 for industrial customers was 7.55 RSD/kWh (~6.4 c€/kWh), while for households and small customers, this price was at the level of 6.84 RSD/kWh (~5.8 c€/kWh). On 31 October 2019, the Energy Agency (AERS) approved new power transmission tariffs, electricity distribution tariffs and guaranteed supply prices. The transmission tariff was increased by 3.9% and the distribution tariff was increased by 2%. Average power price for customers entitled to guaranteed supply at regulated prices (households and small customers) amounts to 7.3 RSD/kWh (~6.2 c€/kWh) – (taxes and duties excluded).

Even after this price modification, the price applied to households is still considerably lower than regional and EU prices. In order to maintain the balance between total production, consumption, electricity exchanges and deviations in 2018, EMS hired balance entities (such as EPS) to perform secondary and tertiary regulation within its regulatory area and also cross-border balancing. At the end of 2018, a total of 63 electricity market participants had a Balance Responsibility Agreement signed with a transmission system operator.

The total balance energy engaged in 2018 was 832 GWh, for which the total weighted settlement price was 47.83 €/MWh. On 14 July 2015, EMS established SEEPEX Belgrade - Electricity Exchange, in partnership with EPEX SPOT, France. It was decided that, at the outset, SEEPEX would manage an organized market with standardized products on a day-ahead market. In 2018 there were registered 18 participants.

The total amount of electricity traded in SEEPEX in 2018 was 2,318 GWh, which is 2.7 times more than in 2017. The share of electricity traded in the power exchange in relation to the electricity delivered to all end customers of electricity was 7.9%.In the wholesale market, the SEEPEX stock market share is 59%, where the wholesale market is actually a bilateral market (buying and selling electricity between suppliers).

The average annual base price was 50.1 €/MWh while the highest hourly rate was reached on 22 November 2018 at 06 p.m. arriving at the level of 126.8 €/MWh. The transmission system operator, EMS, has entered into contracts for emergency energy exchange or cross-border tertiary regulatory energy exchange in cases where the power system operation security or power supply of the country is compromised, either on a natural or commercial basis. In 2018, EMS concluded one-year contracts on a commercial basis with the transmission system operators of Hungary (MAVIR), Croatia (HOPS) and Romania (Transelectrica).

In June 2019, the European Commission adopted an updated Electricity Regulation 2019/943 as part of its Clean Energy Package. One of the provisions is a new emission limit of 550 grams of CO_2 of fossil-fuel origin per kWh of electricity as an eligibility condition for participation in capacity mechanisms.

Renewables

Increase of energy production from renewable sources is important in order to reduce import dependency, improve energy security, for environmental protection and for GHG emission reduction. In the primary energy production in Serbia for 2018, energy from renewable energy sources participated with 21% (2.146 Mtoe).

The largest part is biomass with 52%, followed by hydro at 46% and by wind, solar, geothermal and biogas with a total of 2% participation. In accordance with the Energy Community Ministerial Council Decision on adoption of the RES Directive (2009/28/EC), Serbia adopted the National Renewable Energy Action Plan (NREAP) in June 2013. Serbia committed to a binding target for energy from RES of 27% of gross final energy consumption (GFEC) in 2020, compared with 21.2% in the base year 2009. In order to achieve this Serbia plans to provide 2,563 Mtoe from RES utilization in 2020.

The share of RES in the electricity mix is projected to increase from 28.7% in 2009 to 36.6% in 2020 (RES-E), in heating and cooling from 25.6% to 30% (RES-H&C) and in the transport sector from 0% to 10% (RES-T), respectively. These sectorial targets are not binding and do not represent fixed targets for each individual sector, thus they can be changed, i.e. increased in case of quicker development of certain sectors with respect to others. There is progress in a number of new RES installations in Serbia, but dynamics of implementation are not as was expected. Table 5.223 illustrates the progress in NREAP implementation since the base year (2009) covering the three sub-sectors of electricity production, heating/cooling and transport.

Table 5.223 **Serbia – Actual development and projections in NREAP implementation**

Project	2009	2014	2015	2016	2017	2019
GFEC (Mtoe)	9.1	8.5	9.3	9.4	9.6	9.6
Share of RES - E %	28.7	40.68	38.86	29.15	28.71	30.11
Share of RES - H&C %	25.6	30.34	26.77	24.65	24.43	26,64
Share of RES - T %	0	0	0	1.23	1.18	1,14
Overall RES share %	21.02	22.73	21.00	20.98	20.60	21,44

*Scenario with applied EE measures
Source: Ministry of Mining and Energy

It is evident that Serbia is still below the planned RES share level in GFEC. There are economic, political and other reasons for this. Firstly, the average Cost of Capital (WACC) is higher than in other parts of Europe because of political instability and banks' distrust in the legal and judiciary system. Access to capital is expensive and banks have the perception of a high risk factor for RES investment in Serbia.

Furthermore, there is a shortage of institutional capacity and experience in the implementation of new technologies, as well as an evident chronic delay in by-laws and secondary legislations adoption of incentive measures for small-scale private investments, such as solar PV or solar water heaters.

Res -Electricity Sector

As defined in the Energy Development Strategy 2025-2030 and actual NREAP, Serbia should have already installed 1092 MW of RES by 2020, 1300 MW by 2025 and a further 1700 MW by 2030.

Besides the large hydropower electric plants owned by EPS with total power generation capacities of 2.986 MW, including 614 MW in pump storage, the government has delegated the investment in generation by utilization of renewable energy sources, to the private sector and to private-public partnerships, supported by incentive measures (Feed-In Tariffs).

From 2014 to the end of 2020 independent producers built 514 MW utilizing RES energy, in 121 Small HPPs, 107 solar–photovoltaic plants and tens of wind and biogas installations. Some additional plants (304 MW) are currently under construction or in a testing stage.

Privileged producers entitled to a feed-in tariff are paid by the state-owned electricity incumbent "EPS Supply", according to the power purchase agreements. The guaranteed purchase price in the form of a feed-in tariff is being passed on to customers through a surcharge applied to all electricity end-users. Current surcharge for all customers is 0.093 RSD/kWh. (~ 0.078 €/kWh).

Table 5.224 **Serbia - Independent privileged electricity producers in feed-in tariffs – 2019 (MW)**

Privileged RES	MW - Active	MW - On hold
Independent mini HPPs	69.4	28.7
Independent Solar PP	8.8	/
Independent Wind PP	330.0	236.0
Independent Biogas PP	22.5	37.0
Independent Biomass PP	2.4	2.4
Landfill gas and sewage gas PP	/	3.1
Waste fired PP	/	30.2
Fossil fired high efficiency CHP	21.9	14.0
Total	**455**	**351.4**

Source: Ministry of Mining and Energy

Table 5.225 **Serbia - electricity produced by privileged producers on Feed-in-tariffs (GWh)**

RES sources	2015	2016	2017	2018
Hydro	151.2	192.4	183.2	265.9
CHP High Efficiency	44.3	78.2	112.4	105.8
Biogas	22.0	34.1	71.3	95.5
Solar	10.0	11.1	11.1	10.5
Wind	0.4	26.2	48.4	150.4
Total	**227.9**	**342.0**	**426.4**	**628.1**

Source: AERS – Annual Report 2018

Privileged producers are exempted from balancing responsibilities costs during the entire 12 years. They also enjoy priority in the takeover of the total produced electricity into the transmission or distribution system, except if operation security is jeopardized.

With regard to the promotion of RES, Serbia has been applying the feed-in tariff model since 2009, and periodically revised and updated it as in 2011, 2013 and 2016.

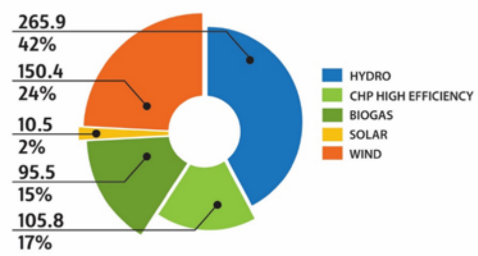
8.2		0.5 - 2	8,447 - 0,493*P
8.3		2 - 10	7,46
9	Waste fired power plant		8,57

Source: Ministry of Mining and Energy

Planned additional electricity installation (1092 MW) and production of (3635 GWh) by RES in 2020 was envisaged mostly for hydro, wind and biomass. In the current situation (end of 2020) there are new additional and installed RES capacities (514 MW) and 304 MW still in construction. In 2018, Serbia had a production by privileged producers in the amount of 628 GWh.

Figure 5.262 **Serbia - Electricity generated by privileged producers in 2018 – 628 GWh**



Source: EPS

Despite the considerable potential in renewable resources, there has been limited progress other than the hydroelectric sector mainly in the form of small hydro power plants. Hydro power generation is a proven and mature technology coupled with traditional national knowledge and experience in the construction of hydro power stations.

It took a few years for the new system of incentives to come to life, and then to gain investors' confidence in the functioning of the system, as well as in the preparation of appropriate projects especially for large power plants.

As announced by the government there will be a partial modification of the existing legal framework for the promotion of the use of RES, such as the introduction of tenders for large wind and solar power plants, as a mechanism that will enable the allocation of capacity and granting of the status of privileged producers according to the criterion of the lowest offered price.
Scaling up electricity from renewables will be crucial for the decarbonisation of Serbia's energy system.

Res - Heating Sector

As defined in the Energy Development Strategy 2025-2030, RES used for heating and cooling should increase from 1,059 ktoe in 2009 to 1,167 ktoe in 2020 which will amount to 10.2% of total energy used in this sector. Most of the change should be achieved by increased use of biomass.

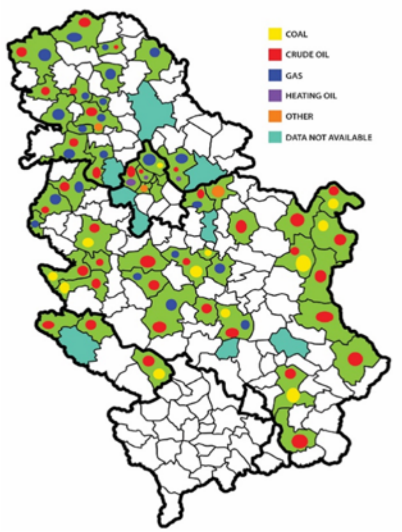
The use of biomass by CHP plants will need to increase by 33%, individual household use by 34%, biomass district heating systems by 16% and biogas CHP systems by 7%, compared to 2009. Direct supply of wood biomass from forests and other forested land for energy production in 2015 was 1,011ktoe and should increase to 1,200ktoe in 2020.

There are also the local district heating systems (DHS) in 58 cities and towns across the Serbia with total installed capacity of about 6.900 MW (42% in capital city of Belgrade), more than 2.100 km of distribution network and 23.500 heat-transmitting substations. The average age of the boiler units used in the distribution networks and heat-transmitting substations is 21-24 years. The primary energy sources used to produce heating energy are natural gas (77.7%), coal (8.8%), heating oil (13.5%) and sporadic application of biomass.

Currently about 47% of households in Serbian cities and towns are connected to local District Heating Systems while in rural areas coal and wood (especially in mountainous areas) are the main fuel sources for heating. Imported fossil fuels generate a serious deficit in the state budget (about 2 Billion €).

On the other hand, biomass availability is higher than planned consumption, so there is sufficient space for fossil fuel substitution with biofuels.

Map 5.68 **Serbia - Installation of District Heating Systems by Fuels**



Source: Ministry of Mining and Energy of the Republic of Serbia

In the energy balance of final energy consumption in Serbia in 2018 the use of biomass reached about 12%. In order to further increase this percentage, in the course of 2018, the Ministry launched a three-year project concerning the replacement of heating oil and coal as fuels in district heating systems with biomass.

Production and consumption of solid biomass for heating purposes includes not only firewood, but also pellets and briquettes. Biomass production in 2017 in Serbia was 1.084 Mtoe, of which the largest part of 0.804 Mtoe was consumed in households. The share of other renewable energies (like geothermal or solar) is marginal. On the consumer side, the final heating consumption in 2018 through district heating systems and industrial heating facilities amounted to 0.74 Mtoe (households 0.41 Mtoe, industry 0.21 Mtoe and others 0.12 Mtoe). Additionally, firewood and derived wood products final consumption in 2018 was 1.04 Mtoe. Households are the largest consumers (0.87 Mtoe) followed by industry (0.15 Mtoe).
Whenever possible, heat production is combined with electricity generation or other technological processes in which hot water is a by-product. Production of electricity and thermal energy for heating purposes takes place in the following plants:

- TPP Nikola Tesla A for district heating of Obrenovac (steam coal units)
- TPP Kostolac A for district heating of Požarevac\and Kostolac (steam coal units)
- TPP Kolubara A for district heating of Lazarevac
- CHP Novi Sad, Zrenjanin and Sremska Mitrovica, for process steam and district heating

The renewed project "Building heating pipeline "Belgrade – Obrenovac" using thermal energy from TPP TENT A – 600 MWth at the expense of reducing available capacity for electricity generation from 150 MWe, will provide heat for more than 50% of the consumption of the heating plant in New Belgrade.

There are good examples for biomass utilisation in district heating systems. The Sremska Mitrovica heating plant uses sunflower husks. One of Belgrade's heating plants uses pellets and wood. Biomass boilers are installed in Pirot, Priboj and Šabac and are used to heat public buildings, primarily schools. The other available biomass by-products and wooden pellets are currently exported to the EU.

So far, the state does not subsidize the production of heat from RES, since only feed-in tariffs for electricity production exist. In order to provide additional support for the activities related to energy production with the use of RES in combined heat and power production, the Government of the Republic of Serbia adopted the Regulation on Incentive Measures for CHP Generation.

According to the current legislation, local self-government bodies define the conditions for acquiring the status of privileged heat producer. Municipal self-governments monitor energy consumption, energy development planning, application of energy efficiency measures and the use of RES at local level predominantly for heating purposes. According to the existing rules, privileged thermal energy producers are the producers using RES in the process of thermal energy production and fulfilling the conditions in terms of energy efficiency. The local self-government unit prescribes incentive measures and conditions for acquiring the status of a privileged producer.

Eligible heat producers are entitled to subsidies, tax, customs and other exemptions. However, incentive mechanisms to increase the share of renewable energy in DHSs are very rare in the Western Balkans. Therefore, establishing and operating comprehensive incentive mechanisms is key to harnessing the great potential that DHSs can provide for the decarbonisation of the energy sector.

Res - Transport Sector

Alternative fuels and alternative energy sources represent one solution to the problem of environmentally friendly vehicles that do not produce harmful emissions and, in the case of Serbia, also decrease the usage of imported of fossil fuels.

While a certain framework has been established for electricity and heat production from RES activities, the use of Renewable Energy Sources in the Transport sector (RES-T) is still very limited. The actual share of energy from renewables in transport, instead of the 10% target is close to 0%. Serbian petrol stations do not offer yet organic fuels, and for many years they have been waiting for a regulation on the obligation to mix biofuels in diesel fuels.

The unfavorable business climate is further accentuated by uncompetitive taxation (excise duties) and lack of incentives. Moreover, some key regulatory measures are not implemented or are missing, such as monitoring and reporting requirements, or certification. Reliable data on the consumption of biofuels in the transport sector will be available upon the adoption of by-laws which regulate the sector of biofuels in accordance with the Directive 2009/28/EC. There is considerable agricultural resource within Serbia to produce biofuels and the country is already a major exporter of agricultural raw materials for biofuel production elsewhere. Given Serbia's strong agricultural output there is considerable potential to supply feedstock for local biofuel production.

Hundreds of farmers and enthusiasts in Serbia have taken "energy self-sufficiency" seriously and are producing fuel for their tractors, cars or heating up their homes for half the price from a gas station. The government is expected to prescribe in more detail the share of biofuels in the market, reporting entities of the system for placing biofuels on the market and their obligations. Only biofuels certified to fulfil sustainability criteria may be taken into account when estimating the achievement of objectives set by the NREAP.

Res - Potential in Serbia

Serbia has a great potential for the development of renewable energy. Serbia's RES technical potential is estimated at 5,65 Mtoe per year. Up to now only ~ 2 Mtoe (35%) of this potential is utilised. Some 1,121 Mtoe (2018) of biomass (mainly as fuel wood) and 0,979 Mtoe of hydro energy (2018) of this potential is already in use. The further development of available potential must be justified in terms of sustainability and taking into account economic, environmental and social feasibility parameters.

Figure 5.263 **Serbia - RES – technically usable potential 2018**

5

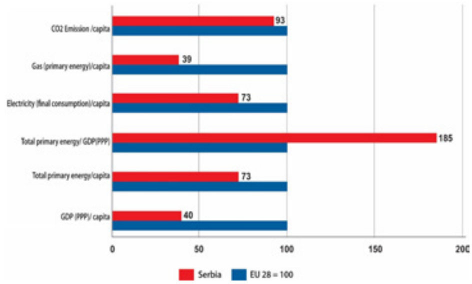
Energy Effiiency and Cogeneration

Energy efficiency (EE) is one of the main objectives in the national energy strategy, helping to enhance energy security, contribute to economic growth and ensure environmental sustainability. Policy creation and implementation of the EE measures is assigned to a department in the Ministry of Mining and Energy.

On the supply side there are a lot of activities (by companies at national level) dedicated to improving energy efficiency in energy transformation, transmission and distribution sectors. On the consumption side, planned EE actions include measures in the residential building sector, public and commercial building sector, industrial and the transport sector. Measures include legislative and infrastructure procedures, that will lead to a reduction of final energy consumption. Compared to the European Union, gross domestic product of Serbia (per purchasing power parity) in 2018 was at 40%, consumption of total primary energy per capita at 73% and final electricity consumption at 73%. Energy intensity, defined as total primary energy consumption per gross domestic product unit (per purchase power parity) was 1.8 times higher than the European average.

The greater energy intensity stems partly from inevitable technical losses in the process of primary energy transformation (mostly lignite) into electricity. Serbia's economy is characterised as high energy intensive. This is also due to low efficiency in industry and households as well as because of aged technologies that are still in use. Further differences in the structure of final energy consumption, compared to the EU, is the high share of household consumption in Serbia. Moreover, it should be noted that industrial production in Serbia today is significantly lower than in the late 80's.

Figure 5.264 **Serbia - Comparative energy indicators of Serbia and EU 2018-**



Sources: IEA, Eurostat, WB, SORS Statistical office RS, compiled by AERS

The framework of the EE activities in Serbia can be illustrated by two main documents, by two laws that regulate final energy consumption and energy sources in Serbia. They are:

- Energy law ("Official Gazette of the Republic of Serbia", no. 145/2014)
- Law of efficient use of energy ("Official Gazette" no. 25/2013)

Requirements of the Directive 2006/32/EC about efficiency of final energy consumption and energy services (ESD) have been applied in Serbia through these two laws. In the meantime, Directive ESD was replaced by a newly formed Directive 2012/27/EU about Energy Efficiency (EED), whose obligatory implementation for the contracting parties of the Energy Community started at the end of 2017.

In line with its commitments under the Energy Community Treaty, Serbia approved its first National Energy Efficiency Action Plan (NEEAP) in 2010. This plan detailed the activities that were to be undertaken in various sectors with the overall aim of reducing energy consumption by 9% between 2010 and 2018. An updated NEEAP (2013-2015) has been adopted in 2013.

The third NEEAP (2016 to 2018) was adopted in late 2016 and was prepared in a format defined by Energy Community and in accordance with the requirements of Directive 2006/32/EC. It also included a number of elements of the Energy Efficiency Directive (EED) 2012/27/EU, by which the indicative target for Serbia is that primary energy consumption does not exceed 17,981 Mtoe and final energy consumption does not exceed 13,103 Mtoe in 2020.

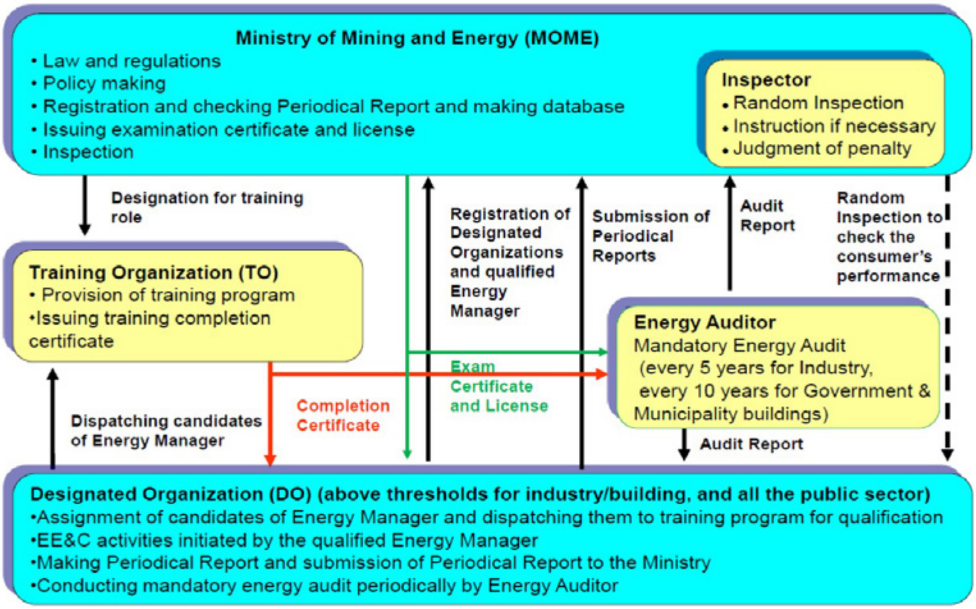
The realized data for 2018 show the consumption of primary energy (15,802 Mtoe) and the final energy consumption (8,599 Mtoe) – both significantly bellow the projected consumption. Periodical creation of NEEAP (4th - for the period from 2019 to 2021, and the 5th - for the period 2022-2024) will include analysis of existing measures from previous plans and a list of new ones.

In line with the Law on Efficient Use of Energy provisions, in 2017 Serbia introduced an Energy Management System (SEM) project supported by JICA, Japan and financed by the Global Environment Fund and UNDP. SEM covers approximately 70% of final energy consumption. Target sectors for energy audit (by licensed energy managers) and energy efficiency improvements include:

• municipalities with over 20.000 inhabitants,
• commercial buildings with consumption more than 1000 toe,
• industrial sector with consumption more than 2500 toe and
• all government facilities with working space more than 2000m2

5

Table 5.227 **Serbia - Framework of Energy management system – SEM**



Source: Ministry of Mining and Energy

SEM identified 79 cities and towns, 72 industrial facilities and 8 enterprises in trade and the rest of the public sector – all fulfilling the scope for audit and potential improvements. The Ministry of Mining and Energy has authorized the Faculty of Mechanical Engineering of Belgrade University to perform training of authorized Energy Managers and energy advisers and has established the energy management system data base – SEMIS. There is a rulebook about type of data, deadlines, manner and form in which audits are to be carried out and findings submitted. As of March 2018, 180 individuals obtained a license to become an Energy Manager.By a decree in 2014, the government introduced a new financing instrument – an energy efficiency budgetary Fund (and a 2014 Energy efficiency measures financing Programme) – and allocated 2.6mill € from the state budget to it. Those monies are used in 11 municipalities for improving heating facilities.

In 2016, the Fund had assets of 1.5mil€ and the funds were distributed to 15 communities. Generally, these funds are small and grossly insufficient for the implementation of all planned energy efficiency projects.

For example, the necessary funds for implementation of measures to improve EE of buildings in the public and commercial sectors (planned for implementation in the 3rd NEEAP) are estimated at 58mil€ per year.

Hence it is necessary to improve the current operation of the budgetary Fund or change the secondary legislation. Fund's increased resources may be achieved through donations, fees or by favorable loans from international financial institutions.

The overall results of the Budgetary Fund for 4 years are as follows: Investment of 3.5 mil€ has been secured for 39 projects (27 finished so far) with 30% contribution by municipalities, expected energy savings of about 9.4 GWh and a reduction of CO_2 emissions of about 4150 t/year. The state financing for energy efficiency has been improved in 2018. The government introduced a fee for all energy sources (electricity, oil products, natural gas) in the amount of 0.015 RSD/kWh (~0.012 c€/kWh) for electricity, 0.15 RSD/l for oil products, and 0.15 RSD/m³ for natural gas. The expected revenue from these fees is about 9 mil €/year.

By Energy Community's assessment, Serbia has achieved a relatively high level of implementation of the EE acquis. It is understood that success in the implementation of previous NEEAPs is primarily based on the implementation of large systemic measures that have covered broad end-users of the population. Good practices that had been developed and introduced include:

- Introduction of energy labeling scheme aligned with the EU practice. From producers of electricity, heat generators, water heaters to household appliances
- Improvement of the thermal envelope of the public and private buildings
- Modernization of indoor and outdoor public lighting systems
- Promotion of ESCO-energy service companies (ESCOs cover 35 street lighting systems)
- Ongoing certification of buildings, secondary regulations of the Law on Construction and Planning
- Introduction of Energy Management System (SEM), based on Japanese experience

All results on the achievements of the 9% energy savings by 2018 should have been available in the 4th NEEAP which was planned to be adopted in 2019, but the work is still ongoing.

Currently, the Ministry for Mining and Energy has identified 150 new projects which had been realized until 2018 with total energy savings of 17 ktoe (197 GWh). For 2020 energy efficiency targets Serbia calculated both an annual 1% renovation target for central government buildings (57 buildings, about 405.000 m²) and a 0,7% target under the energy efficiency obligation scheme. Through the auspices of the Energy Community, significant offers from international financial institutions (IFIs) and financing facilities providing different funds, donations and credit lines with related technical support have been secured.

Some of the successful examples are as follows:

- German development bank KfW has launched two subsidized loan programs, with technical assistance, "4E Facility" and "Eco-loans" for energy efficiency improvement in public and private legal entities. Total amount of 120 mil€ is disbursed to local commercial banks to finance investments.
- The project "Rehabilitation of the District Heating System" started in 2012 and ended in 2019. 68 projects, worth over 52 mil€ were completed. Technical measures financed largely from the KfW soft loan (45 mil€) and the rest of funds was contributed by the Republic of Serbia.
- Improving energy efficiency of public facilities in four cities in Serbia is covered in the "Energy Efficiency and Energy Management in Municipalities" (PEEUEO) project and is a collaboration between Swiss and Serbian government. It covers 26 buildings (17 primary schools, 6 kindergartens, 1 high school and 2 health facilities). The project worth is 10 milCHF, of which the Swiss donation is 88%.
- The ongoing program for the rehabilitation and renovations of Central Government Buildings is financially secured by the state Budgetary Fund for EE and support of 45mil€ investment loan by the Council of Europe Development Bank. The inventory (total useful floor area of over 250m2) and 1% target for central government buildings that must be renovated, was adopted by the government in August 2018.

The European Bank for Reconstruction and Development (EBRD), the European Investment Bank (EIB), the World Bank and German development bank - KfW are becoming increasingly engaged in providing affordable lending terms to large scale energy efficiency schemes. Despite Serbia's progress in implementing the energy efficiency framework enacted by the Energy Community Treaty there are still a number of barriers such as the energy price distortions, subsidies, lack of consumption-based billing for heating, financing problems, lack of by-laws, lack or institutional capacity, lack of public awareness etc.

The residential sector still consumes the largest share of final energy. Serbia has high carbon footprint due to a legacy of high-energy intensity and inefficiency in buildings and industry. On the other hand, Serbia has a tremendous potential to improve energy efficiency. It is generally realized that energy efficiency is the cheapest, cleanest and most secure source of energy.

CHP Installation

Construction and generation of Combined Heat and Power Plants (CHP) is planned, promoted and governed by a series of laws, bylaws, strategies, action plans, decrees, and regulations:

- The Law on Energy (Official Gazette of the RS 145/14), Articles 2, 3, 16, 20, 21, 30, 57, 70, 74, 80, 85, 345, 380, 386.
- The Law on Efficient Energy Use (Official Gazette of the RS 25/13). Articles 5, 45, 46 introduce certain requirements for the construction of new and reconstruction of existing heat and electricity generation facilities.
- Energy Sector Development Strategy of the Republic of Serbia for the period by 2025 with projections by 2030 (Official Gazette of the RS 101/15).
- Energy Strategy Implementation Program for the period from 2017 until 2023 (2017).
- 3rd National Energy Efficiency Action Plan (2017) establishes, for the first time, EE measures in the energy generation sector and expected results of primary energy savings.
- Regulation stipulating the requirements and procedure for acquiring the status of a privileged power producer (Official Gazette of the RS 56/16).
- Regulation stipulating incentives for the production of electricity from renewable energy sources and from high-efficiency electricity and thermal energy cogeneration - (Articles 1, 2, 4, 7) (Official Gazette of the RS 56/16).

Future Power Systems in Serbia and SEE region will have different patterns from those observed today. Less lignite-fired power plants, more RES, more energy efficiency and an increased need for flexibility. Combined Heat and Power (CHP) production plants will play a significant role in energy transition and the inevitable decarbonisation.

Table 5.228 **Serbia - CHP installations in 2019**

CHP installations	Fuel	Electricity MWe	Heat MWt
Public CHP Novi Sad	Natural gas/Oil	250	355
Public CHP Zrenjanin	Natural gas/Oil	110	140
Public CHP Sremska Mitrovica	Natural gas/Oil	32	33
Industrial CHPs (7)	Natural gas/Oil	10	
Industrial CHPs (5)	Biogas	5	

Source: Ministry of Mining and Energy

The generation of public CHPs in 2018 was 351 GWh in electricity and 0.039 Mtoe in heat (steam and hot water) supplying local district heating systems and some industrial customers. Industrial CHPs utilizing natural gas and biogas in combined processes, along with additional industrial energy auto producers (in closed systems) in 2018 generated about 543 GWh in electricity and 0.264 Mtoe in heat.

After certain technical modifications in some of the EPS thermal power plant units, during certain periods of the year, aside from their main activity of electricity generation, they are delivering additional heat and hot water for industrial and local district heating purposes in municipalities of Obrenovac, Lazarevac and Pozarevac. Three thermal power plants of Panonske CHPs produce heat for the cities of Novi Sad, Zrenjanin, and Sremska Mitrovica.

The renewed project of heat pipeline connecting Thermal Power Plant Nikola Tesla A with the city of Belgrade (29 km), will connect the 600 MWth New Belgrade Heating Plant with the aim of supplying base load heat for the entire heating season. This project will place part of the said TPP in the CHP regime, and increase heat supply security for the largest heat consumer in Serbia. Construction contract valued at EUR 195 mil. was signed with the Power Construction of China, with a three-year implementation period. Promoting heat and electricity produced by high-efficiency combined heat and power plants (CHP) is part of the energy efficiency policy aimed at increasing energy efficiency in the power/heat sector.

The status of a privileged power producer for a power plant, and/or part of a power plant for high-efficiency electricity and heat cogeneration with an installed electrical capacity of up to 10 MW requires an annual efficiency level of 75%. The total annual efficiency level of a cogeneration power plant (η) is the ratio between the total net energy produced (electricity and heat) and energy values of consumed primary fuels. Current installation (March 2020) of highly efficient cogeneration with the status of privileged CHP producers is at the level of 26 MW and additionally 9.9 MW with the temporary privileged power producer status.

Three CHPs in District Heating Systems of Belgrade and Novi Sad with natural gas-fuelled high-efficiency plants already belong to the group of privileged power producers. Serbia has a major CHP cogeneration potential in the following sectors: industry, district heating systems, hospitals, farms, hotels, schools and kindergartens. Industrial companies that incorporate natural gas-fuelled high-efficiency plants for combined heat and power generation (CHP) up to 10 MW are entitled to acquire a privileged power producer status and receive an incentivised purchase price for the electricity delivered.

The Waste Management Strategy of Serbia (2010-2019) refers to incineration of waste, its energy use and integrated approaches to waste management. The Decree governing incentives for renewable energy sources includes support for power plants using municipal waste as a fuel.

Beyond electricity and heat generation, there are a number of advantages to considering waste-to-energy with a view to the significant reduction of waste volumes and landfill space, especially important for urban areas.

The Vinca project (12 km from Belgrade) as part of the Waste Management System for the City of Belgrade is a Private Public Partnership designed to improve the current solid waste disposal practice. The project is the first project of its kind in Serbia. It includes an Energy from Waste facility with the nominal combustion capacity of about 340,000 t/year of municipal waste, which will under the CHP regime generate a combination of electricity (~192 GWh/y) and heat (~175 GWh/y). Maximum gross electricity output will be 32,4 MWe and maximum heat output to district heating 56,5 MWth.

A PPP contract was signed in September 2017 between the City of Belgrade and Suez, France, ITOCHU, Japan and Marguerite Fund, Luxemburg. This project valued at EUR 370 mil. will be in full operation by late 2022. In a transition agenda, natural gas is likely to become competitive with lignite, especially in industrial and community CHP units. Since 2013, NIS, Petroleum Industry of Serbia has launched eleven small CHP gas generation units in oil and gas fields, with the total capacity of 9.6 MW.

Similarly, the Serbian oil company NIS, under a joint venture with the Gazprom Energoholding, completed construction of 200 MW combined steam and gas cycle CHP plant in Pancevo. The main purpose of this CHP plant inside the NIS' oil refinery complex in Pancevo is to meet the growing need of the refinery for power and process steam. CHP plant will consume about 300 mil. cubic meters of natural gas per year, while its annual electricity generation will be around 1,400 GWh. Up to 65% of the electricity generated will be sold on the domestic and regional open electricity market, while also covering the needs of the Pancevo refinery for electricity and steam. The plant is not part of any support scheme and no subsidies are planned for its operation. The project costs are valued at some EUR 180 mil. and it is completion is expected by mid-2021.

As announced by Gazprom Energoholding, the construction of four more natural gas fuelled CHP plants in Serbia is also under consideration, in Belgrade, Novi Sad, Nis and Kragujevac.

Energy Investment Outlook

Energy Investment

Projects under construction	**mill €**	**Period**
ELECTRICITY		
Thermal Power plants		
EPS - New block TPP Kostolac B3, 350 MW (2200 GWh)	716	up to 2020
NIS - CHP 140 MW (910GWh) on Natural gas, Pancevo	180	up to 2020
EPS - Thirteen projects for emission reduction SO_2, NOx	536	up to 2023
Wind Power Plants		
Private investors - Seven new wind farms up to 500 MW (1303GWh)	706	up to 2020
EPS - Wind park 66 MW (150 GWh) East Serbia	97	
Solar PV plants		
EPS - Solar plant 9.95 MW (13GWh) Petka, near Kostolac		
EPS - Solar plant 97.2 MW (115GWh) near Kostolac	84	up to 2025
Transmission and Distribution		
EMS - Trans-Balkan corridor 400KV phase 1	164	up to 2023
EPS - Reconstruction of old and construction of new 110/x KV substations	196	2017-2023
EMS - Reconstruction and reinforcing of 110 KV power lines and cables	49	2017-2023
EPS - Metering infrastructure and distribution network automation	90	2017-2023

5

COAL PRODUCTION		
EPS - Opening new mine fields - replacement capacities, Kolubara, Kostolac	1125	2017-2023
EPS - Coal quality management in Kolubara and Kostolac basins	150	2018-2025
EPS - Measures for efficient coal production	81	2017-2020
OIL & PETROLEUM		
NIS - Refinery Pancevo reconstruction and modernization "Deep Processing"	330	2017-2020
Transnafta - petroleum product pipeline Pancevo - Smederevo	30	up to 2022
Ministry ME - Mandatory stock of crude oil and petroleum	12	2017-2022
NATURAL GAS		
Transportgas - Interconnection Serbia - Bulgaria 109km	86	up to 2022
Gastrans – Main transport pipeline Bulgaria-Serbia-Hungary 403 km	800+	up to 2021
Banatski Dvor - Underground Gas storage from 450 to 800 mil m^3	65	2020-2023
Srbijagas - Main and distribution gas pipelines	378	2017-2023
HEAT		
EPS - Heating pipeline TPP NT Obrenovac - Belgrade 600 MWth	165	up to 2023
District Heating Systems - Transition to boilers on biomass	100	up to 2021
Total	**6 140+**	

Potential projects	**mill €**
Hydro PP Srednja Drina, 321 MW	819
Hydro PP Velika Morava, 148	360
Small hydro PP, 191 locations, 387MW	500
PS Hydro PP Bistrica, 680 MW (4x 170MW)	560
PS Hydro PP Djerdap 3, Phase 1, 600MW (2x 300MW)	400
Thermal PP Nikola Tesla B3, 750MW	1600
Thermal PP Kolubara B, 2x 375MW	1500
Thermal PP Novi Kovin, 2x 350MW	1330
Thermal PP Stavalj, 300MW	700
Thermal CHP Novi Sad, 340MW	400
CHPs - Belgrade, Nis, Kragujevac, Novi Sad	819
Transportgas - Interconnection Serbia – Romania 6km	6
Transportgas - Interconnection Serbia – Croatia 95 km	32

SLOVENIA

Slovenia

Economic and Political Background

Slovenia's GDP declined at a sharper pace of 4.5% year-on-year in the fourth quarter of 2020, below the 2.4% contraction seen in the third quarter. GDP fell 6.7% in 2020 as a whole after growing 3.2% in 2019, marking the worst drop since the Great Recession.

Household spending fell 14.5% in Q4 2020, which was significantly below Q3's 0.6% contraction, dragged down by the tightening of restrictions throughout the quarter. However, public consumption improved to a 2.8% increase in Q4 (Q3: +1.3% y-o-y). Meanwhile, fixed investment rebounded, growing 2.0% in Q4 and contrasting the 0.8% decrease logged in the prior quarter, amid a robust construction sector.

Exports of goods and services contracted at a softer pace of 0.4% year-on-year in the fourth quarter (Q3: -9.5% y-o-y). In addition, imports of goods and services declined at a milder rate of 2.0% in Q4 (Q3: -12.5% y-o-y), marking the best reading since Q1 2020. While exports and imports of goods returned to growth, services trade was depressed by muted travel and tourism.

Going into 2021, the economy should benefit from the recent easing of restrictions in February and the likely further lifting of lockdown measures in the coming months, which should drive a rebound in private consumption. However, delays in the vaccine rollout and a slower-than-expected resumption of international trade pose downside risks to the outlook. IMF estimates that Slovenia's GDP will expand by 5.2% in 2021, significantly higher than -6.7% in 2020.

After the motion of no confidence against Slovenia's Prime Minister Janez Janša failed to secure a parliament majority due to the lack of support of DeSUS members of the parliament, the proponent of the vote, DeSUS president Karel Erjavec stepped down as president and also left the party. The government support that grew stronger with the occasional support of DeSUS parliamentarians was weakened when a split happened in the coalition member Modern Centre Party. Eventually, a new non-aligned parliamentary group was found out of the former SMC and DeSUS members of the parliament and the developments left the parliament split almost exactly in half, which became evident at a recent vote against the current Speaker Igor Zorčič.

5

Energy Policy

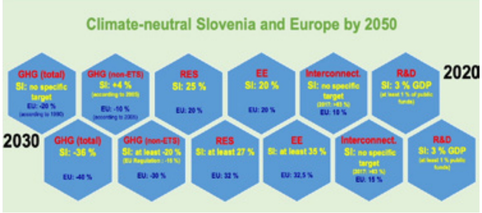
National Energy Policy

The government of Slovenia laid down its energy policy objectives and main priorities for the development of energy system in its Resolution on the National Energy Programme (adopted in June 2004) and with the Energy Act (latest revision from October 2019). The Energy Act provides a legal basis for the adoption of national strategic documents that will determine the long-term trend in energy supply and use. Unfortunately, since 2010 Slovenia was unable to reach the national consensus and adopt a new National Energy Strategy. The latest attempt failed in 2018 when the National Energy Concept was not adopted. Although the National Energy Concept (NEC) was strongly debated there was no actual agreement on a final framework. However, it is promising that despite the fact that the NEC was not adopted, national policy follows the recommendations and requirements of the "Clean Energy for all Europeans" Package.

By the end of February 2020, the Slovenian government adopted the country's first National Energy and Climate Plan (NECP). In the context of NECP, the main goal of the Slovenian national energy policy is to ensure secure, sustainable and competitive energy supply. At policy level, energy efficiency is perceived as the most important instrument for the future sustainable growth.

The new Slovenian NECP has been recognized as the first step towards establishing a solid base for further development of the national economy in the framework of its transformation towards low-carbon society and reaching goals of 2050. In order to avoid possible future problems the government has to develop a comprehensive follow-up plan to improve and accelerate activities for the implementation of the proposed measures and projects. NECP is foreseeing support and promotion of investments in new "climate neutral" technologies, renewable energy, energy efficiency as well as the comprehensive improvement of the electricity distribution network. An overview of key energy and climate policy goals of EU and Slovenia for 2020 and 2030 is shown in Figure 5.268.

Figure 5.268 **Key energy and climate policy goals of Slovenia for 2020 and 2030**



Source: NECP

Regarding the share of RES in the final energy consumption Slovenia is facing many challenges. Due to the high share of transport in the final energy consumption it is more difficult for Slovenia to proceed at the same pace as the other countries because the permitted share of RES in transport fuels is, due to requirements from engine manufactures, still relatively low. This means that in order to reach higher overall share of RES in final energy consumption, a significant increase of RES share in other sectors, in electricity production and heating, is required (see Table 5.229).

Table 5.229 **Overall and sectorial RES targets for Slovenia**

	2020	2022	2025	2027	2030
Renewable contribution as a share of energy from renewable sources in gross final consumption of energy in 2030 and indicative trajectory	25% 21.1% in 2018	25.4%	25.9%	26.3%	SI 27% EU 32%
RES -H&C share*	36.4%	36.8%	37.3%	38.9%	41%
RES - E share	33.5%	35.0%	37.2%	39.2%	43%
RES - T share	10.2%	11.5%	13.4%	16.1%	21%
RES - T share as contribution to overall target	10.8%	11.8%	13.2%	14.1%	15%

Source: NECP

Public acceptance in Slovenia, of the need for the further development and utilization of RES, namely hydro and wind power plants, similarly to other countries, is relatively low and represents a crucial obstacle for reaching higher shares of RES in electricity and in the final energy consumption. In the framework of the NECP, significant potential for the future increase of the electricity production from solar PV has been identified. However, it also means that accelerated development of the electricity distribution network must be ensured. The electricity distribution network has been recognized as the backbone of the transition to a carbon neutral society since it must be capable to accept and absorb a larger number of heat pumps, electric vehicles and electricity generation from solar PV without significant disturbances in power quality for the final consumers. In this context and considering the current situation (environmental constrains, long lasting spatial planning procedures, strong opposition from local communities, results of Strategic Environmental Assessment for NECP) the Slovenian objective of 27% renewable share in gross final energy consumption for 2030 seems very ambitious.

Slovenia is also in the process of preparing its Long-Term Strategy to achieve the greenhouse gas emissions reductions needed to meet commitments under the Paris Agreement and EU objectives. National ambition is to reach climate neutral Slovenia by 2050. Hence, the activities related with the preparation of the Long-Term Strategy and the NECP are harmonized.

Governmental institutions

Ministry of Infrastructure, Energy Directorate is the main governmental institution responsible for energy in Slovenia. The Ministry is responsible for cooperation in preparation and implementation of EU's energy and climate legislation, preparation of national legislation in the field of energy, preparation of strategic documents and action plans and implementation of measures to reach set targets in the fields of energy efficiency, renewable energy sources, security of supply and sustainable development of energy systems. Ministry of Infrastructure is working in cooperation with other ministries i.e. Ministry of Environment and Spatial Planning that is responsible for environment, climate action and reduction of air pollution, Directorate for transport at Ministry of infrastructure, responsible for transport policy in Slovenia.

The Energy Agency is responsible for the following tasks:

- regulation of the network activities, which covers economic regulation of all electricity and gas system operators and the regulation of the network with respect to issuing consents to the general acts
- regulation of the supply of heat and energy gases
- ensuring a reliable supply of natural gas
- promoting the production of electricity from renewable sources and cogeneration
- promoting efficient use of energy
- monitoring of the electricity and natural gas market
- supervising the providers of energy operators' activities
- protecting the rights of consumers

Borzen's principal activity is the implementation of public service obligation relating to the organization of the electricity market that includes organization of the electricity market in the strict sense and the activities of the Centre for RES/CHP Support which administers the electricity feed-in support scheme for RES (renewable energy source) and CHP (high-efficiency cogeneration) power plants.

ELES is the operator of the electric power transmission network of the Republic of Slovenia. ELES endeavors to strategically, responsibly and sustainably plan, construct and maintain Slovenia's high-voltage transmission network in three voltage levels: 400 kV, 220 kV and a part of 110 kV.

Plinovodi d.o.o. is a company managing the natural gas transmission network. Their main operational goal is provision of long-term, reliable, high quality, price competitive and environmentally acceptable transmission of natural gas.

The HSE Group is the largest producer and seller of electricity from domestic sources on the wholesale market in Slovenia and the largest Slovenian producer of electricity from renewable sources. Their other activities include extraction of lignite, provision of auxiliary services needed for the functioning of the electricity system in Slovenia, and management and implementation of energy and environmental projects.

GEN energija is the second largest producer of electricity in Slovenia producing and selling electricity from the Nuclear power plant at Krško, Sava hydropower plants and Thermal power plant Brestanica. It is also very active in energy trading through its daughter company GEN-I.

Eco Fund's main purpose is to promote development in the field of environmental protection, energy efficiency and renewable energy sources. It is the only specialized institution in Slovenia that provides financial supports for this kind of projects. The financial assistance is offered mainly through soft loans from revolving funds and since the year 2008 through grants.

Energy Demand and Supply

National energy demand

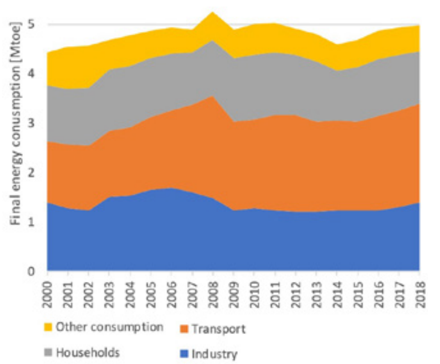
In 2018 Slovenia's total final consumption (TFC) reached 4.97 Mtoe, being 0.6% higher than the year before. Compared to 2000, TFC was higher by 12.4%. The highest TFC was reached in 2008 with 5.26 Mtoe. Since 2007, the transport sector has had the largest share in total final consumption. Its share increased from 28% in 2000 to 36% in 2007 and 40% in 2018. Before 2007 industry was the most important sector. In 2018 its share was 28%. Households in 2018 represented 21% and other uses 11%.

The transport sector is the only sector where energy use increased in the period between 2000 and 2018, being 65% higher in 2018 compared to 2000. Energy use in industry decreased by 1%, in households by 5% [1] and in other sectors by 22%.

The most important fuels are liquid fuels with 46% share in 2018 (i.e. 2.30 Mtoe), followed by electricity with 24%, renewables and waste with 14%, gaseous fuels with 12%, district heat with 4% and solid fuels with 1%.

Non-energy use amounted to 53 ktoe in 2018 decreasing by more than half compared to 2000 (57%). First data for 2019 indicates that final energy consumption will be slightly lower than the year before.

Figure 5.269 **Sectoral structure of final energy consumption in Slovenia during the period 2000-2018**



Other consumption includes commercial and public services, energy use for non-road machinery in agriculture and forestry
Source: SORS

Table 5.230 **Final energy consumption in Slovenia (Mtoe)**

	2000	2010	2017	2018
Industry	1,40	1,27	1,29	1,38
Transport	1,23	1,79	1,96	2,00
Households	1,12	1,33	1,12	1,07
Other consumption	0,68	0,61	0,57	0,52
Final energy consumption	4,43	5,00	4,94	4,97

Source: SORS

[1] Statistical data for Renewable energy use in households have been improved in 2009 resulting in large increase of its use therefore the trend is being influenced by this. On the other hand energy data for other sectors does not include renewable energy consumption so decrease is also an effect of switch to renewable energy sources in this sector

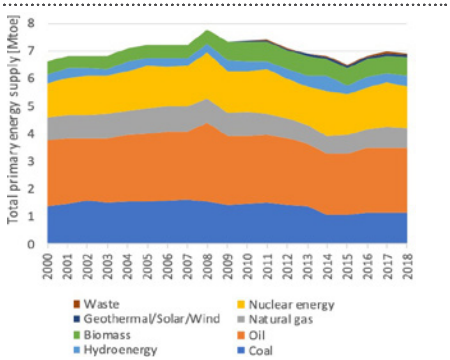
National energy supply

In 2018, Slovenia's Total Primary Energy Supply (TPES) reached 6.86 Mtoe. This was 0.9% lower than the previous year, and 5.7% higher than 2000. The highest TPES was reached in 2008 with 7.65 Mtoe. In the period 2000-2008 TPES on average grew by 2.1% per year, while in the period 2008-2018 primary energy decreased by 1.2% per year. Slovenia's GDP in the period 2000-2018 increased by 50.2%.

Oil products are a dominant energy source with a share of 34.0% in 2018, followed by nuclear energy and coal with 21.8% and 16.3%. Natural gas represented 10.5%. The share of all renewables was 16.5% increasing from 11.9% in 2000. The most important RES is biomass, followed by hydro energy.

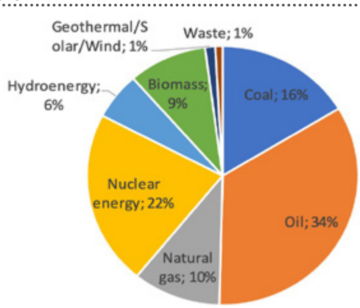
In 2019, no bigger changes were anticipated compared to 2018.

Figure 5.270 **Slovenia's total primary energy supply**[2]



Source: SORS

Figure 5.271 **Structure of total primary energy supply (2018)**

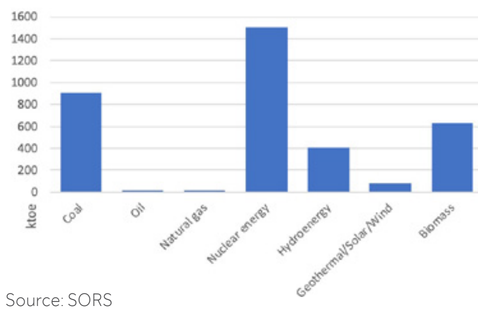


Source: SORS

Energy balance

Domestic production of primary energy in Slovenia increased between 2000 and 2011 from 3.25 Mtoe to 3.85 Mtoe and afterwards it decreased in 2012 to 3.59 Mtoe and remained at that level until 2018 (3.54 Mtoe). Also, its structure did not change significantly in the period 2000-2018. Nuclear is country's main source of indigenous energy, accounting for 42.5% in 2018. Coal represents 25.4% of domestic production, being decreased from 34.3% in 2000. Share of RES has increased from 24.3% to 31.7%.

Figure 5.272 **Domestic production of primary energy in 2018 in Slovenia (Total = 3,542 ktoe)**

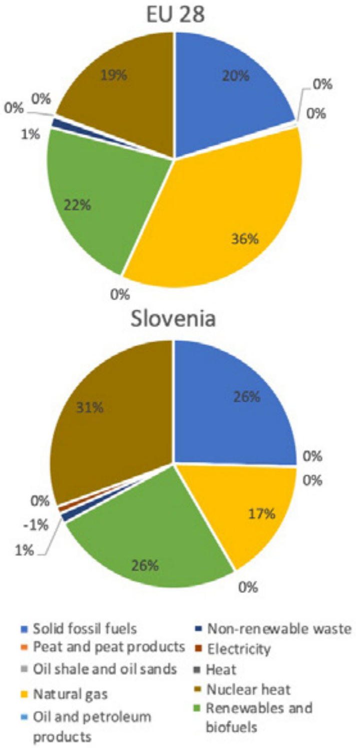


Source: SORS

Energy mix

The energy mix of Slovenia is roughly similar to the energy mix of EU 28. The majority of energy falls into four categories: natural gas, coal, nuclear and renewables, but there are large differences in their shares. For EU 28 the largest share falls to natural gas, while in Slovenia natural gas has the smallest share between the four largest categories. In Slovenia the largest share corresponds to nuclear, while in EU28 this category has the smallest share. Coal and renewables have higher share in Slovenian energy mix compared to EU28.

Figure 5.273 **Structure of Gross inland energy consumption in Slovenia and EU28 (2018)**



Source: EUROSTAT

The energy mix of final energy consumption is presented in the Table 5.231. In industry, electricity and natural gas are the dominant energy sources, in transport oil products are by far the most dominant source, in the residential sector the most dominant source are biofuels (wood biomass) while in other sectors electricity and oil products are the most dominant sources. Oil products are by far the most dominant source in total final energy consumption.

Table 5.231 **Energy mix per sector and of total final energy consumption (2018)**

	Industry	Transport	Residential	Other	Total
Coal	38	0	0	0	38
Crude Oil	0	0	0	0	0
Oil Products	115	1.904	125	159	2.303

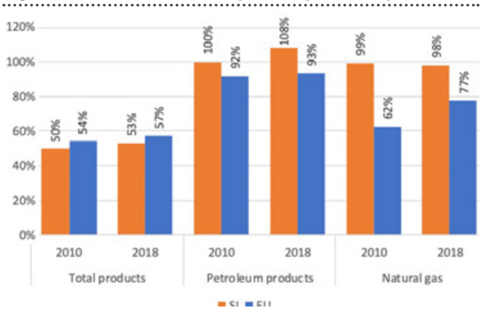
Source: SORS

Degree of energy dependence

Based on EUROSTAT data, Slovenia's import dependency in 2018 for all fuels was 53% and it was very close to EU 28's average import dependency of 57%. The lower import dependence of Slovenia is due to the higher share of nuclear energy and RES in TPES. On the other hand Slovenia has very high import dependency for petroleum products where it is completely import dependent and also for natural gas where the import dependency is also close to 100%. Petroleum products are imported from various countries but mostly from neighboring refineries in Austria, Croatia, Hungary and Italy. The energy trade deficit (mostly on oil) expressed in percentage of GDP is high and well above the EU average.

Figure 5.274 **Slovenia's import dependency**



Source: EUROSTAT

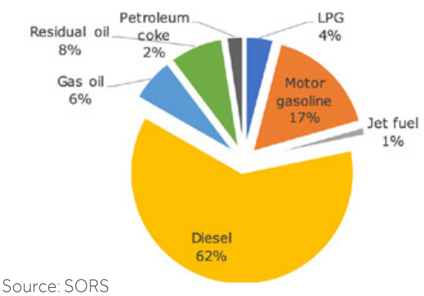
[2] Oil includes crude oil and oil products

Oil and Petroleum Products

(a) Oil supply and demand

Slovenia maintained a small production of crude oil. In 2018 it amounted to 0.9 ktoe, while there was no production of petroleum products. In 2018 primary supply with imported petroleum products amounted to 2.352 Mtoe, recording an increase of 0.4% compared to 2017. The highest level of consumption was achieved in 2008 with 2.879 Mtoe. The first data for 2019 is indicating a slow decrease in consumption. The most important petroleum product in Slovenia is diesel oil with a 62% share, mainly used in transport, followed by motor gasoline with 17% share, also mainly used in the transport sector. Transport is by far the highest user of petroleum products in Slovenia.

Figure 5.275 **Structure of oil demand in Slovenia for year 2018**



Source: SORS

Table 5.232 **Key oil data for Slovenia**

Share in TPES	37%	38%	34%	34%	34%

Source: SORS

(b) Oil imports/dependence

There were no crude oil imports to Slovenia in the period 2010-2018. As was mentioned above, Slovenia imports all petroleum products that are consumed. In 2018 the import of petroleum products in Slovenia amounted to 4.664 Mtoe, while almost half of this (2.115 Mtoe) was exported to other countries, resulting in net import of 2.548 Mtoe, that is 8% more that the consumption (2.352 Mtoe).

(c) Upstream sector - domestic production and exploration

Slovenia is fully dependent on imports of all petroleum products and has no operating refineries. Petroleum products are usually imported from neighboring refineries in Italy, Croatia, Hungary or Austria.

(d) Downstream and midstream sectors infrastructure (Refineries, Pipelines, Storage, Terminal and Domestic Oil Market)

There are no operating oil pipelines in Slovenia and all petroleum products for commercial use are transported by conventional means of transport, such as road tracks and railways.

Most of the existing oil terminals in Slovenia are used for non-commercial purposes (i.e. compulsory and strategic reserves). There is only one major entry point for petroleum products in Slovenia. It is situated in the Port of Koper, known as the Instalacija Sermin (Sermin Installation) and it is operated by Petrol. According to the annual report of Petrol, in 2018 the Sermin Installation reached a record volume of petroleum products. Sermin Installation storage facilities are designed for the storage of diesel, petrol and extra light fuel oil, as well as storage of biodiesel and additives dedicated to improve the quality of petroleum fuels. The Installation has 480,000 m3 of reservoir capacity in 23 tanks, a tanker pier, a truck and wagon filling station and all associated infrastructure for the storage and handling of petroleum products.

The major players in the Slovenian market of petroleum products are Petrol d.d., OMV Slovenija d.o.o. and MOL Slovenija d.o.o.

(e) Security of supply

According to the Slovenian oil stockpiling policy, the maintenance of emergency oil stocks is delegated to the state-owned Agency of the Republic of Slovenia for Commodity Reserves (ZRSBR). Over the years, the Agency for Commodity Reserves has created a stable portfolio of time-tested operators of storage facilities (so called tank farms) for petroleum products located across Slovenia's borders and the Agency is successfully maintaining the mandatory level of compulsory stocks according to the Council Directive 2009/119/EC. The Agency's obligation has been determined as «a minimum daily average net import for 90 days» compared to previous year consumption. The level of emergency stocks has to be adjusted until March 31st every calendar year (until that date, the stocks may correspond the country's stockholding obligation of two years before). According to the Agency's Annual report for 2017[3], at December 31st 2017, the Agency had at its disposal 603,369 tons of petroleum products that were equivalent to emergency stocks lasting 94.83 days. Of this quantity, the stocks owned by the Agency for Commodity Reserves were around 522,369 tons or 87% and the delegated stocks (cross border tickets) totaled 81,000 tons or 13%. Also, 67.6% of stocks were stored within the territory of the Republic of Slovenia and 32.4% were stored abroad (cross border stocks in Germany, Hungary, Italy, the Netherlands and Slovakia).

(f) Planned new projects

There are no new planned oil projects in Slovenia.

Natural Gas

(a) NG Supply and Demand (in bcm)

Domestic production of natural gas in Slovenia is very small although it increased in 2017 and 2018, amounting 0.016 bcm in 2018, being several times higher than in 2015. Production takes place in the North-Eastern part of Slovenia.

National gas demand has been decreasing from 2005 reaching minimum demand in 2014 amounting to 0.77 bcm (see Fig. 12). In the period 2015-2017 demand increased, reaching 0.91 in 2017. In 2018 a slight decrease has been observed resulting in consumption of 0.89 bcm. First data for 2019 are indicating a small increase in consumption (0.5%).

Source: SORS

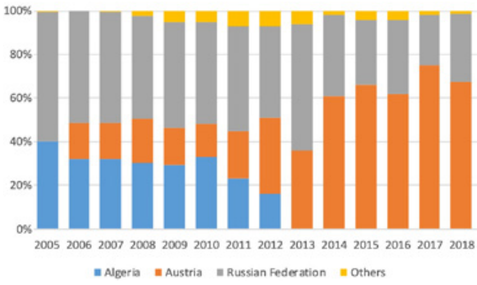
(b) NG Imports (in bcm)

In 2018 Slovenia imported gas from Austria, Russia and Italy. 70% has been purchased from Austria, while the majority of the rest from Russia and just 0.5% from Italy. In the period from 2014 to 2018 the majority of natural gas came from Austria, while in the past Italy (natural gas of

[3] https://www.dbr.si/wp-content/uploads/2018/04/Letno-porocilo-ZRSBR-2017-sprejeto-na-Vladi.pdf

Algerian origin) was another important source country. However, it is important to mention that natural gas from Austria is mainly originating from Russia.

Figure 5.277 **Natural gas imports in Slovenia by Country of Origin**

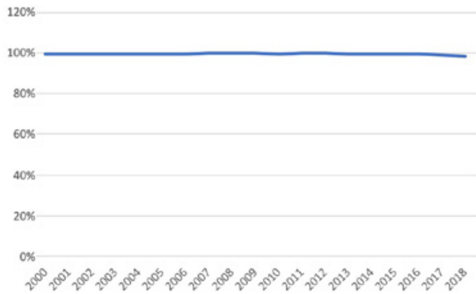


Source: SORS

(c) Natural gas dependence (%)

Since Slovenia has a very small production of natural gas, it is almost fully dependent on imports to cover its demand (Table 5.233, Figure 5.278).

Figure 5.278 **Natural gas dependency of Slovenia**



Source: SORS

(d) Domestic Production and Exploration

Domestic production in 2018 amounted to 0.016 bcm representing 1.8% of Slovenia's demand. Exploration of natural gas in Slovenia is ongoing in just one location in the North-Eastern part of Slovenia, in a reservoir known as "Petišovci globoko". Exploration of natural gas began in 1943, and from 1963 until 2017 some 342 mcm of natural gas had been extracted. Peak production was reached in 1989, when more than 33 mcm was produced.

Company Geoenergo d.o.o., which is a subsidiary of Slovenian oil company Petrol, is the holder of an exploitation concession contract for this field since 2002, giving it the exclusive right for oil and gas exploitation and production in this area until 2022. The project of natural gas production is a joint venture of Geoenergo d.o.o. and Ascent Resources, being undertaken by Ascent Slovenia Limited, the project manager. In 2017 a contract with the Croatian oil and gas company INA was signed for delivery of raw natural gas to the Molve processing facility, since they were not able to obtain a permit for the construction of a natural gas processing facility in Slovenia.

Geoenergo and Ascent are facing strong opposition for this project from environmental organizations. The latest decision of the Slovenian Environmental Agency, that a separate permit for hydraulic fracturing is needed, has once again delayed production. Ascent Resources plans to take a multi-pronged legal action against Slovenia because of this creating further delay for the implementation of the project.

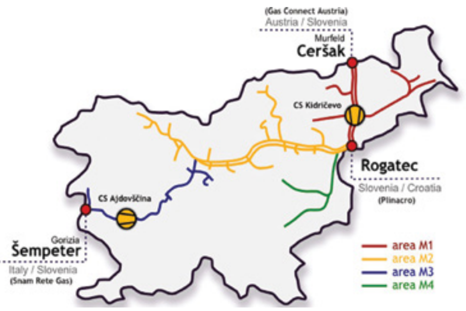
Exploration of natural gas is regulated by the Mining Act (Official Gazette of the Republic of Slovenia No. 14/2014).

(e) Infrastructure (Pipelines, Storage)

In 2018 the Slovenian transmission system consisted of 946 km of pipelines with nominal pressure of more than 16 bars and 211 kilometers of pipelines with nominal pressure below 16 bars. The transmission system operator (TSO), company Plinovodi, also controlled 203 metering-regulation stations, 44 metering stations, seven reducing stations and two compression stations in Kidričevo and Ajdovščina. The transmission system is connected with the neighboring system in Austria at point Ceršak, with Italy at point Šempeter pri Gorici and Croatia at point Rogatec. At the border point with Italy bidirectional flow is possible, at the border point with Austria flow from Austria to Slovenia is possible and at the border point with Croatia from 2019 onward bidirectional flow is possible. In the short term future additional expansion of the network is foreseen, connecting the southwest region to natural gas network and enabling the use of natural gas for electricity and heat production in Ljubljana.

In the period between 2016 and 2018 the daily technical utilization at exit points did not change. The largest daily capacity was at point Ceršak (import 76 GWh), followed by point Rogatec (export 43 GWh/import 7 GWh) and Šempeter (import 27 GWh/export 13 GWh). At all points the transmitted amount of gas decreased in 2018 compared to previous years. The largest daily utilization of the transmission network in 2018 occurred on 28th of February with 2,427,255 kWh/h not reaching contract or physical congestion.

Map 5.69 **Typology of Slovenian transmission system with relevant points**



Source: Plinovodi

Slovenia's distribution network in 2018 consisted of 4.827 kilometers of pipelines, increasing by 1.8% compared to previous years

LNG terminals

In the past there were talks of an LNG terminal to be constructed in Slovenia, but environmental concerns stopped the plans.

Currently the nearest location for an LNG terminal is on the island Krk, in Croatia. The project has received backing and financial support from the European Commission. Technical capacity of floating terminal will depend on the technical characteristics of the terminal, while the maximum annual delivery of natural gas is expected to be 2.6 billion cubic meters in the first stage of the project. The maximum annual delivery of natural gas will depend on the future pipeline development. The project is planned to receive their first batches of gas in 2020.

Storage

In Slovenia there are no underground gas storage facilities. There are also no plans to construct any storage facility in the future. Good connections to European gas network system enable Slovenia to have high security of natural gas supply. The nearest underground gas storage is in Austria with capacity of more than 4.7 bcm, while Slovenia consumes 0.8 bcm per year.

(f) Domestic Gas Market

Slovenian wholesale natural gas market is determined by imports of gas through neighboring transmission systems (Austria, Italy and Croatia). Slovenian natural gas market is open and fully liberalized. Market transparency is ensured by preventing market manipulation and trading on the basis of inside information, a requirement for effective and timely disclosure of inside information, and appropriate legislative framework for market monitoring. In this context the Slovenian Energy Agency, as the market regulator, plays key role.

Interconnector Slovenia - Hungary has been recognized as a "Project of Common Interest (PCI) – 2017" and has been included in a list of projects of Central and South Eastern Europe Connectivity and the Three Seas Initiative. The project for the interconnection between the Hungarian and Slovenian transmission system, as it is reported and described with the PCI status, will enable the bidirectional gas route between Italy - Slovenia - Hungary.

The majority of natural gas consumed in Slovenia is being imported through the interconnection with Austria, where at the gas hub Baumgartner and Austrian storages Slovenian energy traders buy most of the natural gas for the domestic market. In 2018 70% of all gas imports in Slovenia came through the interconnection with Austria. As a result of market liberalization there is a trend in decreasing the number of long-term contracts signed directly with natural gas producers in Russia. According to the Slovenian Energy Agency, in 2018 61.2% of natural gas was purchased on the basis of short-term contracts while the remaining 38.8% was purchased on the basis of long-term ones.

The major players in the Slovenian wholesale natural gas market are listed in Table 5.234. Also, this table contains the so called Herfindahl-Hirschman index (HHI) of the Slovenian wholesale market. The HHI index is calculated by squaring the market share of each company competing in a market and then summing up the resulting numbers. The Slovenian Energy Agency, as the regulator of the energy market, uses this index to determine if the natural gas industry should be considered competitive or is closer to being a monopoly. According to the Energy Agency, natural gas market concentration measured by HHI shows a very high degree of concentration on the Slovenian wholesale market. The HHI value strongly exceeds the limit, which is a boundary between middle and high concentration level.

Table 5.234 **Market shares and the HHI of the natural gas wholesale market in 2018**

Name of company	Market share
Geoplin	80.33%
Petrol	15.57%
Plinarna Maribor	2.71%
GEN-I	1.31%
Adriaplin	0.09%
Total	100%
HHI of the wholesale market	6,704

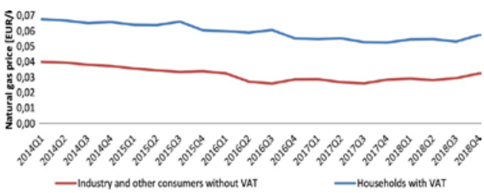
Source: Slovenian Energy Agency

Traditionally, the largest market share in the Slovenian wholesale market belongs to the "Geoplin Company", Ljubljana, which in 2018 had a market share of 80.3%. The second largest market player is the "Petrol Company", which in 2018 had a market share of 15.6%. "Petrol" is also the largest trader and distributer of petroleum products in Slovenia.

In 2018, 23 natural gas suppliers (five less than in 2017) were active in the Slovenian retail market, which according to contracts supplied natural gas to 134,642 consumers (1,312 more than in 2017). Reduction in the number of active natural gas suppliers is the result of merges and acquisitions but also it has to be emphasized that two suppliers left the retail market in 2019. Final consumers can change their supplier at any time. Also, suppliers must publish on their websites offers for household and small business consumers. In 2017 prices reached their lowest level since 2011. In 2018 this trend changed somewhat for certain groups of consumers. However, average prices remained almost unchanged. Compared with neighboring countries, natural gas prices for typical household consumer in Slovenia in 2018 (final prices including all taxes and levies) were lower than in Austria and Italy but higher than in Croatia and Hungary. Also, in 2018 natural gas prices for typical household consumers in Slovenia remained below the EU-28 average. On the other hand final natural gas prices including all taxes and levies for typical industrial consumers in Slovenia in 2018 were higher than in all neighboring countries and remained above the EU-28 average.

The development of natural gas prices in Slovenia since 2014 is shown in Figure 5.279.

Figure 5.279 **Development of natural gas prices in Slovenia**



Source: SORS and Ministry of Infrastructure

(g) National NG policy - strategic plan

According to new Slovenian NECP, national gas is considered as an important transition fuel towards a climate neutral society. Slovenia has already established a favorable legislative framework for electricity production in natural gas fired high efficient cogeneration units.

Additionally, Slovenia has a favorable geographical position in relation to the flow of natural gas in Europe due to its close proximity to the transmission routes from Eastern Europe (from Russia through Slovakia and Austria towards Italy and Croatia) and its border with Italy, where the transmission routes from the Mediterranean Basin and Northern Europe converge. NECP includes concrete measures for the promotion of research cooperation and support mechanisms for joint development projects between companies from different energy sectors, namely electricity, natural gas and district heating. Slovenia is planning different projects to increase the operational security and expansion of its transmission system. In this context NECP, supports the implementation of pilot projects for the production of synthetic methane and hydrogen (indicative target of 10% share of methane or hydrogen of renewable origin in the natural gas transmission and distribution network by 2030).

The future development of the transmission system is in line with the expected physical flows of natural gas and system capacities, including new sources of synthetic gas. In coming years Slovenia will prepare a regulatory and support environment for renewable gas alternatives and based on results of pilot projects, it will determine the maximum hydrogen content in the existing network.

(h) Planned new projects

According to currently valid ten-year gas transmission network development plan for the 2019 - 2028, Slovenia is planning several projects that will increase operational security and support expansion of its transmission network. Additionally, several projects for connecting new natural gas consumers or changing the operational characteristics of gas infrastructure, and projects for developing interconnection points are also envisioned. In this context, expansion of the transmission system includes system pipelines, energy loops, displacements of pipeline sections due to specific settlement modifications, and prevention of landslides.

A previously mentioned new project between Hungary and Slovenia will enable the establishment of natural gas flows between Italy and Hungary via Slovenia, and thus the direct interconnection between these three gas markets. The project will also connect the currently unconnected Slovenian and Hungarian transmission system. Additionally, a group of projects in the corridor of Austria, via Slovenia, towards Croatia have a PCI status. This represents an upgrade of the capacity of existing transmission systems and the establishment of reverse flows between the systems in those three counties.

It is also worth mentioning the upgrade of the District Heating System in the Slovenian capital Ljubljana, which includes replacement of two coal fired cogeneration units at the Thermal Power Plant Ljubljana (TE-TOL) with new natural gas fired combined heat and power plant with total electrical power output of 142 MW. It is expected that this new unit will commence operation by the end of 2021 or at the beginning of 2022 and it will enable significant reduction of GHG emissions in Ljubljana.

Solid Fuels

(a) Supply and consumption

The supply of solid fuels in Slovenia in 2018 amounted to 1.13 Mtoe, a decrease of 1.0% compared to 2017. The majority of solid fuels was used for the production of electricity and heat with 1.08 Mtoe in 2018, while total final consumption including non-energy use amounted to 46 ktoe.

The main solid fuel used in Slovenia is domestic lignite, that is used in the Šoštanj power plant. In 2018 this fuel represented 81% of total solid fuel consumption. Approximately 17% of solid fuels is imported brown coal mainly used in Ljubljana CHP plant, while the rest is coke and anthracite used in industry.

Table 5.235 **Key Solid fuels data in Slovenia**

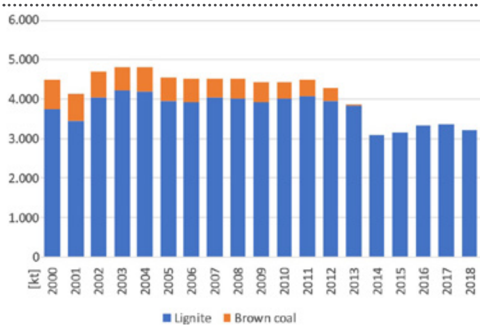
Source: SORS

(b)Local production and exploration

Currently only lignite is produced in Slovenia. In 2018 production accounted at 3.22 Mt, 4.1% less than the year before. Compared to 2000, lignite production decreased by 14%, while brown coal production that was present in 2000 ceased in 2013 with the closure of Termoelektrarna Trbovlje (Thermal Power Plant Trbovlj). Domestic lignite is exploited at the Velenje Coal Mine and all of its output is used at the nearby Šoštanj power plant. It is operated by the Premogovnik Velenje company, which belongs to Holding Slovenske Elektrarne (HSE) together with an underground mine. NECP foresees that coal use for electricity production will decrease by 30% until 2030, having an effect also on domestic production.

Figure 5.280 **Domestic production of solid fuels in Slovenia in the period 2000-2018**



Source: SORS

(c) Deposits

According to Euracol, lignite and brown coal resources in Slovenia are estimated to be 1.256 million tons, located at Velenje (358 million tons), Zasavje (68 million tons) and Goričko (830 million tons), with mineable reserves accounting for 109 million tons.

(d) Coal imports

The majority of solid fuels in the form of thermal coal, that were imported in Slovenia in 2018, corresponding to 80% of total consumption, were used for heat and electricity production in the Termoelektrarna Toplarna Ljubljana Power Station (TE-TOL). The remaining amount was used in the following industrial branches: Manufacture of paper and paper products (13%) and manufacture of other non-metallic mineral products (7%). Domestic indigenous lignite production accounted for approximately 13.1% of primary energy supply in 2018, with imported coal bringing coal's total share to 16.3%. According to NECP, by 2030 Slovenia will abandon the use of imported coal to produce heat and electricity in TE-TOL and any other use in industry.

(e) Planned new projects

Current energy policy foresees the use of coal only in existing installations and until the end of their operational life. According to NECP, Slovenia is planning its coal phase-out strategy which will include all the necessary legislation regarding the gradual closure of the existing Velenje Coal Mine and the restructuring of the coal regions based on just transition principles (Zasavje in Šaleška region).

Electricity

(a)Electricity supply and demand (in TWh)

Gross electricity production in 2018 amounted to 16.33 TWh, up by 20% compared to 2000 or 2.71 TWh. The largest increase in electricity production in the 2000-2018 period came from hydropower plants with 1.06 TWh closely followed by nuclear electricity from the Krško plant with 1.02 TWh. Some 0.37 TWh of electricity increase came from thermal power plants and the rest from photovoltaic plants (0.26 TWh) and wind farms (6 GWh).

The structure of electricity production has slightly changed since 2000, by reducing the share of electricity from thermal power plants, from 37% in 2000 to 33% in 2018, while the share of hydro power plants increased from 28% to 30% and the share of photovoltaic plants increased from 0% to 2%.

In 2018 the total electricity consumption in Slovenia amounted to 13.82 TWh, excluding losses in the distribution and transmission network. Compared to the previous year consumption increased by 1.4% and compared to 2000 it increased by 29.6%. Approximately, 50% of electricity is consumed by industry, with business, direct and closed distribution systems (connected to the transmission network) having consumed 2.08 TWh. Households and the service sector each correspond to 24% of total final electricity consumption. The transport sector represented 2% of electricity use and the energy sector 1%. The hydroelectric pumped-storage power plant at Avče used 252 GWh. Electricity losses in the transmission and distribution networks amounted to 880 GWh. Own use of power plants amounted to 877 GWh.

Electricity consumption in Slovenia, taking into account half of the production from the Krško Nuclear Power Plant (NPP) (since the other half of the plant is owned by Croatia), and own use and loses, was not completely covered with domestic production, reaching 84% in 2018. The lowest consumption share produced by domestic production was reached in 2003 and 2007 at 76%.

(b) Installed Capacity

In 2018, Slovenia's total installed electricity capacity was 3.80 GW and its breakdown is shown in Table 5.236. The largest installed capacity belongs to thermal power plants with 1.54 GW, followed by hydro power plants with 1.34 GW, including pumping-storage facility. Table 5.235 shows the breakdown of installed electricity capacity in Slovenia. Compared to 2005 the largest growth in capacity has been observed in hydro power plants followed by photovoltaics and wind and thermal power plants. Electricity production on photovoltaic and wind power plants increased much less than their installed capacity due to smaller operating hours (approximately by a factor of 4).

Table 5.236 **Yearly electricity production and consumption in Slovenia**

		2000	2005	2010	2015	2017	2018	2019

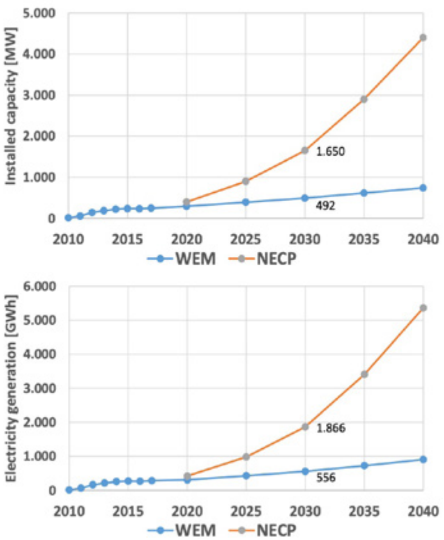
(c) Planned new capacity – investments

According to NECP, up to 2030 the majority of new capacity is planned in decentralized RES electricity generation. Electricity generation in solar photovoltaic plants (PV) represents the largest single development which is environmentally acceptable, in terms of new potential for increased electricity production from RES in Slovenia. Considering sustainability and spatial planning principles, integration of PV modules into buildings will be prioritized. The technical potential in terms of available areas for electricity generation from PV is estimated at more than 20 TWh/year. However, the key limitation is the ability of the existing electricity distribution network to absorb new capacities which also influence the economics of new projects. Estimated development of electricity generation from PV up to 2040 is shown in Figure 5.282, where the blue line represents existing situation and future development in a scenario with existing measures (WEM) and the orange line depicts expected development according to the NECP scenario.

Figure 5.282 **Expected future development of electricity generation from solar PV in Slovenia**

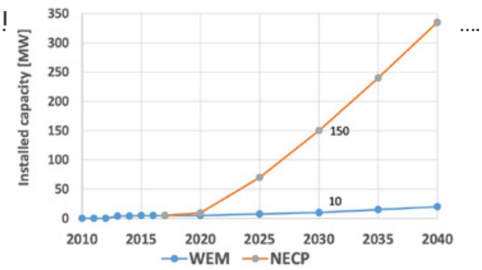


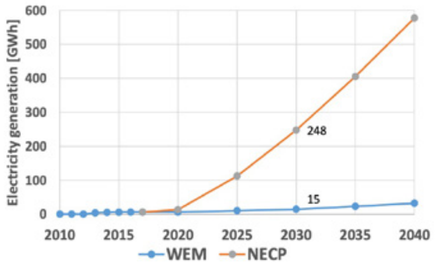
Source: NECP

Regarding the large hydro power plants, the NECP up to 2030 foresees the finalization of HPP Mokrice on Sava River, but only in case that environmental acceptance is achieved. Or in the case that additional measures will be required to ensure coordination and implementation of procedures for overriding public interest for the project (reaching goals of RES in final energy consumption and reduction of GHG emissions over protection of water and nature).

In the field of wind energy Slovenia is facing a similar situation since a significant part of the non-governmental sector and the public strongly opposes any further construction of wind farms. Therefore, in the various scenarios for wind power development NECP foresees that reaching 150 MW of installed capacity up to 2030 will be very challenging for Slovenia. Estimated wind power development up to 2040 is shown in Figure 5.283.

Figure 5.283 **Expected future development of wind**





Source: NECP

As it has already been stated, the upgrade of the district heating system in Ljubljana, includes the replacement of two coal fired cogeneration units at TE-TOL with new natural gas fired combined heat and power plant with total electrical installed capacity of 142 MW. It is expected that this new unit will start operation by the end of 2021 or at the beginning of 2022 and that will enable a significant reduction of GHG emissions in Ljubljana.

Regarding the future use of nuclear power, NECP foresees life extension of the existing Krško NPP. Concerning the construction of a new unit the NECP proposes that a decision about the long-term use of nuclear energy should be taken by 2027. This decision must be based on a comprehensive analysis and should provide the answer about costs and benefits of the potential construction of a new unit in Krško.

The Slovenian transmission and distribution system operators are obliged to prepare 10-year development plans every two years; plans are evaluated and approved by the ministry responsible for energy. In the context of the new NECP, both operators will have to prepare new development plans within nine months after the adoption of the NECP and obtain approval by the ministry responsible for energy. Development plans must cover a period of at least ten years and must be consistent with instruments and measures proposed by NECP. Both plans must consider the strategic national energy policy goals and must be harmonized with each other. Additionally, the physical and financial extent of necessary investments in new facilities must be determined, as well as investments for the renovation and upgrade of existing electricity infrastructure facilities in the transmission and distribution network.

(d) Electricity imports – exports

According to the Energy Agency's annual report, in 2018 some 15,003 GWh of electricity was delivered to the Slovenian transmission and distribution system, which was 19 GWh more than in 2017. The delivery from power plants using RES was 5,177 GWh, which is 698 GWh more than the year before. Power plants using fossil fuels contributed 4,343 GWh or 196 GWh less than in 2017. Due to scheduled maintenance at Krško NPP in 2018, it delivered 5,483 GWh of electricity or 483 GWh less than the year before (2017 was the year without scheduled maintenance works). In 2018 through the transmission and distribution networks, 9,317 GWh of electricity was exported (241 GWh less than the year before), and 8,930 GWh of electricity was imported (203 GWh less than the year before), as shown in Tables 5.238 and 5.239.

Table 5.238 **Net electricity generation and imports in GWh (2018)**

	Volume in GWh
Hydropower plants (large)	4,421
Thermal power plants	4,049
Nuclear power plant	5,483
Small producers (including small CHP units using fossil fuels)	1,050
Total electricity production in Slovenia	15,003
Imports	8,930
Total	23,933

(e) Tariffs

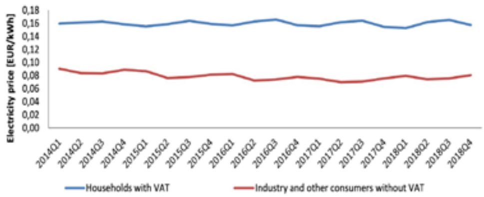
Slovenia has a well-diversified energy mix and hence highly competitive wholesale and retail electricity markets. The Energy Agency monitors the level of wholesale prices in Slovenia and in related markets that affect prices in Slovenia. Also, it regularly monitors the prices in the household and business markets as it receives from the suppliers monthly information on price changes or supply offers in the retail market.

In the retail market, suppliers and traders sign open contracts, in which the quantities of supplied electricity and the time profile of supply are not set in advance. Consumers pay for the supplied electricity according to actual consumption metered by the utility meters. Some 13,879 GWh[4] of electricity, 2.3% more than the year before, was delivered to all consumers in Slovenia in 2018. In the retail market 23 electricity suppliers were active in 2018 and 17 of them supplied household consumers. The final electricity price for consumers in Slovenia consists of:

- the wholesale electricity price which is formed freely in the market, on a daily basis,
- the network charge (it varies regarding voltage supply level and includes charge for the transmission and distribution network - consumers directly connected on transmission network don't pay charges for distribution network),
- levies (for supporting electricity production from RES and CHP, supporting energy efficiency programs and for the operation of the market operator),
- excise duty and
- value added tax (VAT).

The development of electricity prices in Slovenia since 2014 is shown in Figure 5.284.

Figure 5.284 **Development of electricity prices in Slovenia (source SORS and Ministry of Infrastructure)**



Source: SORS and Ministry of Infrastructure

(f) Cross-border interconnections

Slovenia enjoys a high level of electricity interconnectivity with neighboring countries that will be further strengthened in the coming years. In 2017 the level of electricity interconnectivity was 83.6% and well above the EU average. However, the new NECP foresees additional measures and policy instruments for enhancing interconnectivity with neighboring countries (Hungary and Croatia), diversification, auxiliary services, flexibility, energy storage, etc. According to the World Energy Council, Slovenia is one of the strongest Energy Trilemma performers, ranking 12th globally. According to ENTSO-E calculations, Slovenia is expected to retain its transit status in future and will foreseeably be even more exposed to cross-border power flows in all directions, particularly at the borders with Austria and Italy. A vision of the long-term development of the Slovenian transmission network is shown in Figure 5.285.

[4] According to Annual report on the energy sector in Slovenia for 2018 (Slovenian Energy Agency)

Map 5.70 **Vision of long-term development of the Slovenian transmission network**

Source: ELES

The Slovenian power system is interconnected with 3 neighboring power systems:

- Austria (2x400 kV Maribor-Kainachtal and 220 kV Podlog-Na Selu (Obersielach)),
- Croatia (2x400 kV Krško-Tumbri and DV 400 kV Divača-Melina, 220 kV Cirkovce-Žerjavinec and DV 220 Divača-Pehlin, 110 kV Koper-Buje, 110 kV Ilirska Bistrica-Matulji and 110 kV Formin-Nedeljanec),
- Italy (400 kV Divača-Sredipolje (Redipuglia)) and 220 kV Divača-Padriče (Padriciano)).

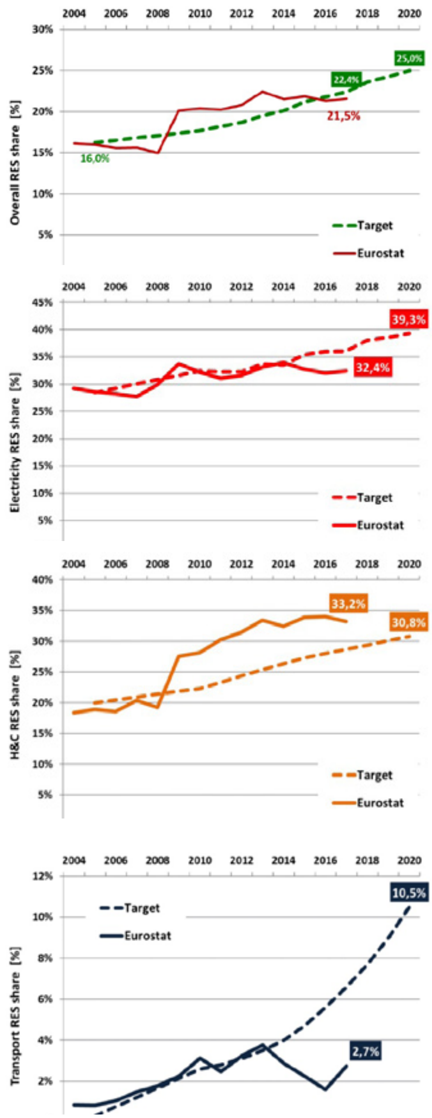
The double circuit overhead line of 400 kV Cirkovce–Pince (new interconnection between Slovenia and Hungary/Croatia) is the on-going EU project of common interest that should enable cross-border interconnection with Hungarian transmission system. Even though this project has faced many difficulties due to long lasting spatial planning procedures it is expected that it will be completed by 2021.

Renewables

(a) Overview of the sector's development

In 2018, Slovenia covered 21.1% of its gross final energy demand with renewable energy sources. This represented a slight decline of 0.5% from the previous year. Compared to 2005 the share increased by 32.1%, but largely this increase happened in 2009 and was to a large degree due to an improvement of RES statistics in households. In the period between 2009 and 2018 the RES share increased by only 4.9%. In this context Slovenia will face difficulties in reaching the 25% target set for 2020.

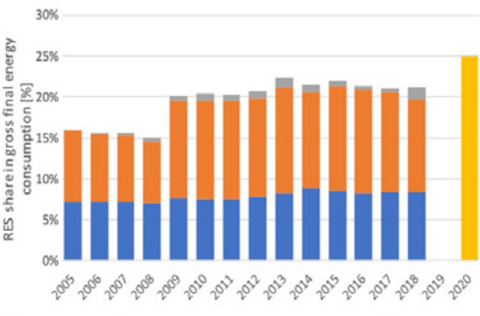
Figure 5.285 **Past trends in the development of RES share in gross final energy consumption (overall and sectorial) compared to target trajectories**



Source: SORS and NECP

The largest contribution to RES share comes from the heating and cooling sector. In 2018 its share in the total RES use was 54%. The main RES fuel in this sector is wood, which is widely used in households. Wood use in households contributes 71% to RES use in heating and cooling, while total RES use in households consumption contributes almost 80%. Electricity from RES contributes 40% to total renewable energy. RES use in electricity production is dominated by hydro energy with 90% share. Liquid biofuels in the transport sector contribute 7%. However, Slovenia's RES share is not increasing due to changes in gross final energy consumption. Compared to 2009 electricity use and energy use in transport increased. Especially energy use in transport is problematic, since the transport sector has a low share of RES. On the other hand, energy use for heating and cooling decreased, most significantly in households, where the RES share is the highest, to a large extent due to implemented energy efficiency measures.

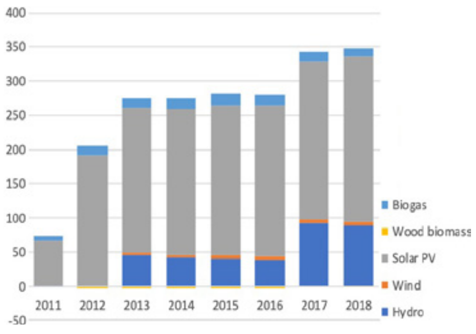
Figure 5.286 **RES share in gross final energy consumption**



Source: SORS

Installed capacity for RES use in electricity production increased in the period 2010-2018 by almost 350 MW. Between 2010 and 2013 a large increase in solar PV capacity has been observed, resulting in 262 MW of extra installed capacity in 2018, compared to 49 MW in 2010. However, it should be noted that between 2013 and 2018 the installed capacity in solar PV increased only by 28 MW, due to changes in the support scheme for RES electricity (i.e. tenders, lower support premium). The second largest increase was observed in hydro power, with 116 MW of new installed capacity in the period 2010-2018. An increase has also been observed in biogas capacity (13 MW) and wind (5 MW).

Figure 5.287 **Development in installed capacity for RES electricity in the period 2010-2018**



Source: SORS, Energy Agency

Slovenia has already exploited the majority of its environmentally acceptable hydro potential. Since 2006 a series of new hydro power plants in the lower part of Sava river have been built but the last one still remains incomplete, due to a lawsuit by environmental groups.

There are plans to build additional hydro power plants in the middle part of the Sava river, but there are once again disputes regarding environmental protection and so a comprehensive environmental impact assessment will have to be undertaken.

In the heating and cooling sector the largest potential lies with wood biomass, since almost 60% of Slovenia's territory is covered by forests, and also geothermal or ambient heat. Wood biomass is problematic from an air quality point of view, since individual boilers are the largest source of PM emissions. Biomass use in households has been declining due to energy efficiency measures (insulation of buildings and substitution of old boilers). It is promising that during recent years heat pumps are also gaining market share in the heating and cooling sector.

In the transport sector biofuels are blended with fossil fuels. Use of biofuels had been increasing until 2013, when a drop was observed, due to the elimination of tax breaks. In 2018 the use of biofuels again increased, but the share of biofuels in the transport sector is still below the technically allowed share of 7% for diesel and 5% for gasoline.

(b) Latest legislation, incentives and national RES policy

The Energy Act sets out the legal framework for supporting RES in Slovenia and fully implements RES directive 2009/28/EC. The new RES directive 2018/2001/EU has to be transposed by 30 June 2021.

Slovenia's RES target share in final energy consumption for 2020 is 25% and for transport 10%. The main policy document is the National Renewable Action Plan, that has been in place since 2010. The sectoral target for electricity has been set at 39.3% and for heating and cooling at 30.3%. Slovenia will have difficulty reaching its national target in 2020. The recently adopted NECP sets targets for 2030 and RES share in final energy consumption must be at least 27%. The target for electricity is 43%, for heating and cooling 41% and transport 21%. A necessary prerequisite for reaching the targets is the intensive implementation of energy efficiency measures while increasing the use of RES.

Electricity production from renewable sources in Slovenia is supported through a support scheme for electricity produced from renewable sources and with high-efficiency cogeneration. A support scheme was first introduced in 2009 and overhauled in 2014. After 2014 financial quotas are determined each year which are offered on tender and the cheapest units are selected. Support is available as guaranteed purchases of electricity (only for units of up to 500 kW) or financial aid for current operation (operating support). The duration of support for new RES generating units is 15 years. Units with nominal power up to 10 MW are eligible, only for wind units up to 50 MW. In 2019 the support scheme was prolonged until the end of 2025. Under the new scheme 5 public tenders (between 2016 and 2019) have been conducted corresponding to 50 million EUR and 285 projects have been chosen with electric power totaling 325.9 MW (RES electricity and CHP units). The largest share falls on wind energy with 215 MW, followed by solar PV with 23.6 MW and small hydro with 14.9 MW. The chosen projects have to be implemented within 3 or maximum 5 years. Due to difficulties in finding appropriate locations and receiving the needed allowances for wind energy it is not very likely that all wind energy projects will be built, meaning that funds have been allocated to projects that will not deliver much needed energy from RES. The consequence of this is that such schemes have much lower effect than it was originally anticipated. Household solar PV units are supported through the promotion of self-supply, while larger units with biomass, solar PV, wind and small hydro are supported through subsidies provided by the Ministry under cohesion policy support.

RES heat in households and public sector is supported through grants given by Ecofund. Funds are available for the installation of heat pumps, wood boilers, solar collectors and higher grants are available for substation of old wood boilers with new boiler or heat pumps, due to air quality problems. New buildings have an obligation regarding the share of energy originating from RES. District heat systems have an obligation regarding their share of heat that has to be produced from RES or by high efficiency CHP. Grants provided by the Ministry and Ecofund are also available for public buildings to install RES for heating. NECP sets 2023 as the date from which the sale of light fuel oil boilers will be banned.

Biofuels in transport are promoted through an obligation by distributers. A strategy for alternative fuels and an operational program have been prepared focusing on the electrification of vehicle fleets. At present there is no biofuels production in Slovenia.

(c) Installed capacity per source

Table 5.240 shows the installed capacity per RES source in 2018 in Slovenia in terms of MW. The capacity of large hydropower is dominant representing 69% of the total RES capacity in Slovenia, followed by solar PV with 17%. Hydro pumped storage represents 11% of the total capacity while wood biomass and biogas each have 2%. Wind energy capacity is only 0.3% indicating the low wind potential in Slovenia. Total RES capacity reached 1,698 MW in 2018.

Table 5.240 **Installed RES capacity (MW) per source**

		2010	2015	2018
Hydro	[MW]	1074	1115	1163
Hydro pumped storage	[MW]	180	180	180
Wind	[MW]	0	5	5
Solar PV	[MW]	49	268	290
Wood biomass	[MW]	33	30	32
Biogas	[MW]	14	32	27
Total capacity	**[MW]**	**1350**	**1630**	**1698**

Source: SORS, Energy Agency

(d) Planned new major projects

Slovenia has plans to further exploit its remaining hydro potential. It is expected that the last hydro power plant in the lower Sava river (HPP Mokrice) will be built at the latest before 2030. The exact date depends on the length and the outcome of the environmental assessment process that has to be conducted again. Lower Sava hydro power plants are managed by Hidroelektrarne na Spodnji Savi, d.o.o., a subsidiary of Slovenia's largest state-owned power utility Holding Slovenian Power Plants (HSE). There are also plans for additional hydro power plants in the middle part of the Sava river.

There are 10 HPP planned with total capacity 300 MW although this project is facing strong environmental opposition. It is possible that only part of the plan will be realized due to restrictions related to Natura 2000 and other environmental concerns. An additional pumping storage unit is also planned after 2030, with a capacity of 400 MW in North-Eastern part of Slovenia (PHPP Kozjak). No other major projects are foreseen.

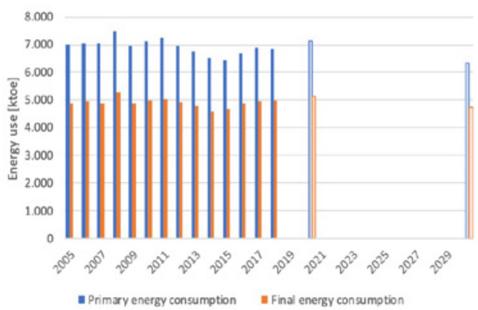
Slovenia does not have a lot of potential for wind power, but a large potential has been identified for solar PV, especially on the roofs of buildings. NECP foresees additional measures that will stimulate larger projects on the roofs of industries or buildings in the services sector that usually have better connections to the distribution network. Projections used for NECP show that by 2030 solar PV capacity could increase to 1,650 MW.

Energy Efficiency and Cogeneration

(a) National targets

Slovenia's national target for 2020 pursuant to Article 3 of Directive 2012/27/EU set in the National Energy Efficiency Action Plan is 7.125 Mtoe expressed in primary energy consumption or 5.118 Mtoe expressed in final energy consumption. The target for 2030, as adopted in the NECP and expressed in final energy consumption, is 4.717 Mtoe. Expressed in primary energy consumption the target is 6.356 Mtoe. Compared to 2007 PRIMES projection targeted energy use is 35% lower, meaning that Slovenia has set a more ambitious target than the one adopted by the EU. In 2018 both final and primary energy consumption were below the target level for 2020 and there is high expectation that the target will be met.

Figure 5.288 **Slovenia's energy efficiency target 2020 and 2030**



Source: SORS

Slovenia in its NECP also defines a target of 20% for final energy use reduction and 70% GHG emissions reduction in buildings. No target has been set for CHP.

Comparison of GDP growth and energy use in the period 2005-2018 shows that between 2005 and 2013 almost no decoupling had been reached, while after 2013 strong GDP growth did not result in energy use increase. Between 2013 and 2018 GDP has grown by 18% while final energy consumption increased by 4% and primary energy consumption by 1%.

5

(b) Incentive-based initiatives in the building sector and EU funded (or otherwise funded) energy efficiency programs in the building sector

In the past energy efficiency measures in the buildings sector were laid down in several documents: National energy efficiency plan, Long-Term Strategy for Mobilizing Investments in the Energy renovation of Buildings with its update, Operational Program for the Implementation of the EU Cohesion Policy in the period 2014 – 2020. A future strategy for the improvement of energy efficiency in buildings has been set in NECP and also in the new Long-Term Strategy for Mobilizing Investments in the Energy renovation of Buildings.

The most important measure for households promoting energy efficiency improvement in buildings is financial support in the form of subsidies or soft loans provided by Ecofund. Funds are available for insulation of façade or roof, new wooden energy efficient windows, mechanical ventilation with heat recuperation, installation of new wood biomass boilers, heat pumps or solar collectors or for a combination of measures. If a combination of measures is applied, a higher subsidy is available. Subsidies are also available for building or purchasing of a passive house or a flat in a passive building.

A special program has been designed for socially weak households, where 100% subsidy for energy efficiency measures in multifamily houses or substitution of old wood boilers is available. In cooperation with social centers a package for reducing energy poverty is also available for them, providing expert counseling on reducing energy use. Funds for the operation of Ecofund come from the government's own funds, by means of contributions paid per energy use in order to increase energy efficiency and from 2014 onwards from the Climate Fund.

In 2018 the Ecofund provided subsidies in the amount of 26.2 million EUR. An important measure supporting funding is energy consulting network for citizens (ENSVET) providing free advice on implementation of energy efficiency measures to households. The Ecofund funds the operation of the network. In the future, special attention must be given to the support of energy efficiency measures in buildings where old people live and to address non-economic barriers in multifamily houses, like reaching agreement on renovation, relations between tenants and owners (new instruments will be prepared for multifamily houses i.e. guaranty schemes).

For buildings in the public sector it is mandatory to implement an energy management system. Funds for public buildings are available as subsidies that are provided by Ecofund and Ministries and as soft loans provided by Ecofund. Cohesion Fund is an important source of funding for this sector. In 2019 some 21.1 mio EUR have been available from the Ministry of Infrastructure for public building renovation, while the Ecofund has planned 1.5 mio EUR in 2019-2020.

Measures are being implemented also through large energy suppliers obligation scheme and energy contracting. Very important action is also related to the education of employees that are involved in the preparation and overseeing of energy efficiency projects. Technical support through the ELENA project for the public sector has been obtained by the government and could provide much needed impetus. It is worth mentioning that Slovenia has set up a project office for the renovation of public buildings providing support to ministries and other public sector entities when preparing projects. However, its operation needs to be enhanced further.

Additionally, special attention must be given to buildings that are protected as cultural heritage. A methodology needs to be prepared for the assessment of qualified costs, while special tenders for grants can be provided under cohesion funds and some pilot projects already have been prepared.

Energy contracting is an important instrument for the implementation of energy efficiency measures in the public sector. During 2016-2018 a total of 32 projects were approved, with increasing number through this period.

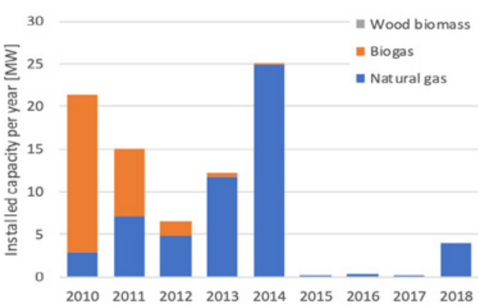
This instrument will be enhanced through the provision of new financial products to ESCOs and other support measures (i.e. trainings, expert and technical support to ESCOs, tool for evaluation of projects) so that it will be used also in other buildings.

Currently valid energy efficiency regulation for buildings has been in use since 2010 (Rules on efficient use of energy in buildings) and needs to be upgraded. New regulation will be prepared based on the Long-Term Strategy for Mobilizing Investments in the Energy Renovation of Buildings and it will be published in due course.

(c) Cogeneration: Regulatory framework, installed capacity

Co-generation of electricity and heat (CHP) is supported through a scheme for electricity produced from renewable source and with high-efficiency cogeneration. The support scheme was first introduced in 2009 and overhauled in 2014. Support is limited to installations up to 20 MW for CHP units. The duration of support for CHP is 10 years. Co-generation is also promoted by mandatory use of RES, CHP and waste heat in the district heating systems (Article 322 of Energy law). For electricity produced in CHP a guaranty of origin can be received.

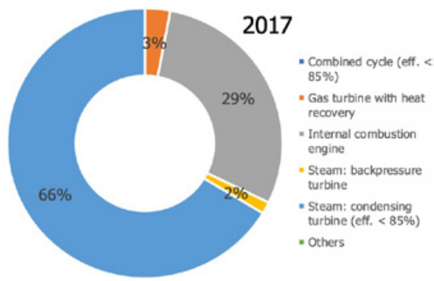
Figure 5.289 **Installed CHP capacity per year for the period 2010-2018**



Source: Energy Agency and Borzen

Between 2010 and 2014 new CHP units were installed totalling 80 MW, mainly using biogas and natural gas. As can be seen in Figure 5.289, after 2014 there has been a break in new installations of CHP units due to an overhaul of the support scheme and preparation of tenders. First tender under the new scheme was published in December 2016. Support for CHP's under this new scheme is less favorable and that is also reflected in the low numbers of newly installed capacities after 2014. Based on SORS data total CHP capacity in 2017 in Slovenia amounted to 374 MW. The structure of installed CHP capacity is presented in Figure 5.290.

Figure 5.290 **Structure of total installed CHP capacity in Slovenia per technology (2017)**



Source: SORS

(d) Planned major projects

A new natural gas fired CHP plant will be built in Slovenia's capital Ljubljana with 142 MW of installed power capacity. The investor is the Energetika Ljubljana Company which is managing the district heating network in Ljubljana. A contract was signed in 2019 and it is expected that the plant will be in operation by the end of 2021 or beginning of 2022. Combined cycle technology will be used, substituting two of three coal fired units and reducing coal consumption by 70%.

NECP foresees an increase of installed capacity in the industrial sector while in district heating a decrease of installed capacity is projected, not taking into account the larger units in Ljubljana and Šoštanj. More than half of the increase in industry is due to biomass units.

Decrease in district heating applications comes from the stagnation of CHP units with gas that are substituted by CHP units and boilers on biomass, heat pumps (using geothermal energy and waste heat), waste heat utilization from industry and solar collectors. Table 5.241 shows a projection of anticipated new CHP capacities until 2030.

Table 5.241 **Projection of new CHP capacities in Slovenian industry based on NECP**

		2020	**2025**	**2030**
Gas turbine	[MW]	0.0	2.0	16.0
Internal combustion engine	[MW]	0.8	1.8	3.2
Internal combustion engine - gasification of biomass	[MW]	3.3	6.6	13.1
Steam turbine & ORC	[MW]	2.6	6.3	10.5
Total	**[MW]**	**6.7**	**16.6**	**42.8**

Source: Jožef Stefan Institute

Energy Investment Outlook

The estimated investment volume for the implementation of the energy part of the NECP scenario from 2021 to 2030 is estimated at over 6.5 billion EUR, which requires excellent cooperation between the most important stakeholders. Table 5.242 provides information on the estimated investments per sector.

Table 5.242 **Estimation of necessary investment needs between 2021 and 2030 for the implementation of energy part of the NECP scenario**

Sector	**Estimated investment needs [million EUR]**
Solar PV	1,208
Wind farms	142
Other RES-electricity projects	13
District heating	80
Upgrades of electricity transmission network	407
Upgrades of electricity distribution network	4,203
Centralized energy supply (including large power plants)	358
Pilot projects (synthetic gas, geothermal, etc.)	100
Total	**6,511**

Source: NECP

Total investment needs for the realization of non-energy projects covered by Slovenia's NECP are estimated at more than 28 billion EUR and include an upgrade of the railway system, deep renovation of existing building stock, sustainable upgrade of the transport sector, etc.

By implementing the proposed measures in the framework of the new NECP, Slovenia can achieve a 6% reduction in final energy use by 2030 and more than 20% by 2040 in comparison to 2017. Additionally, the share of RES and waste in final energy consumption can increase by more than 35% compared to 2017.

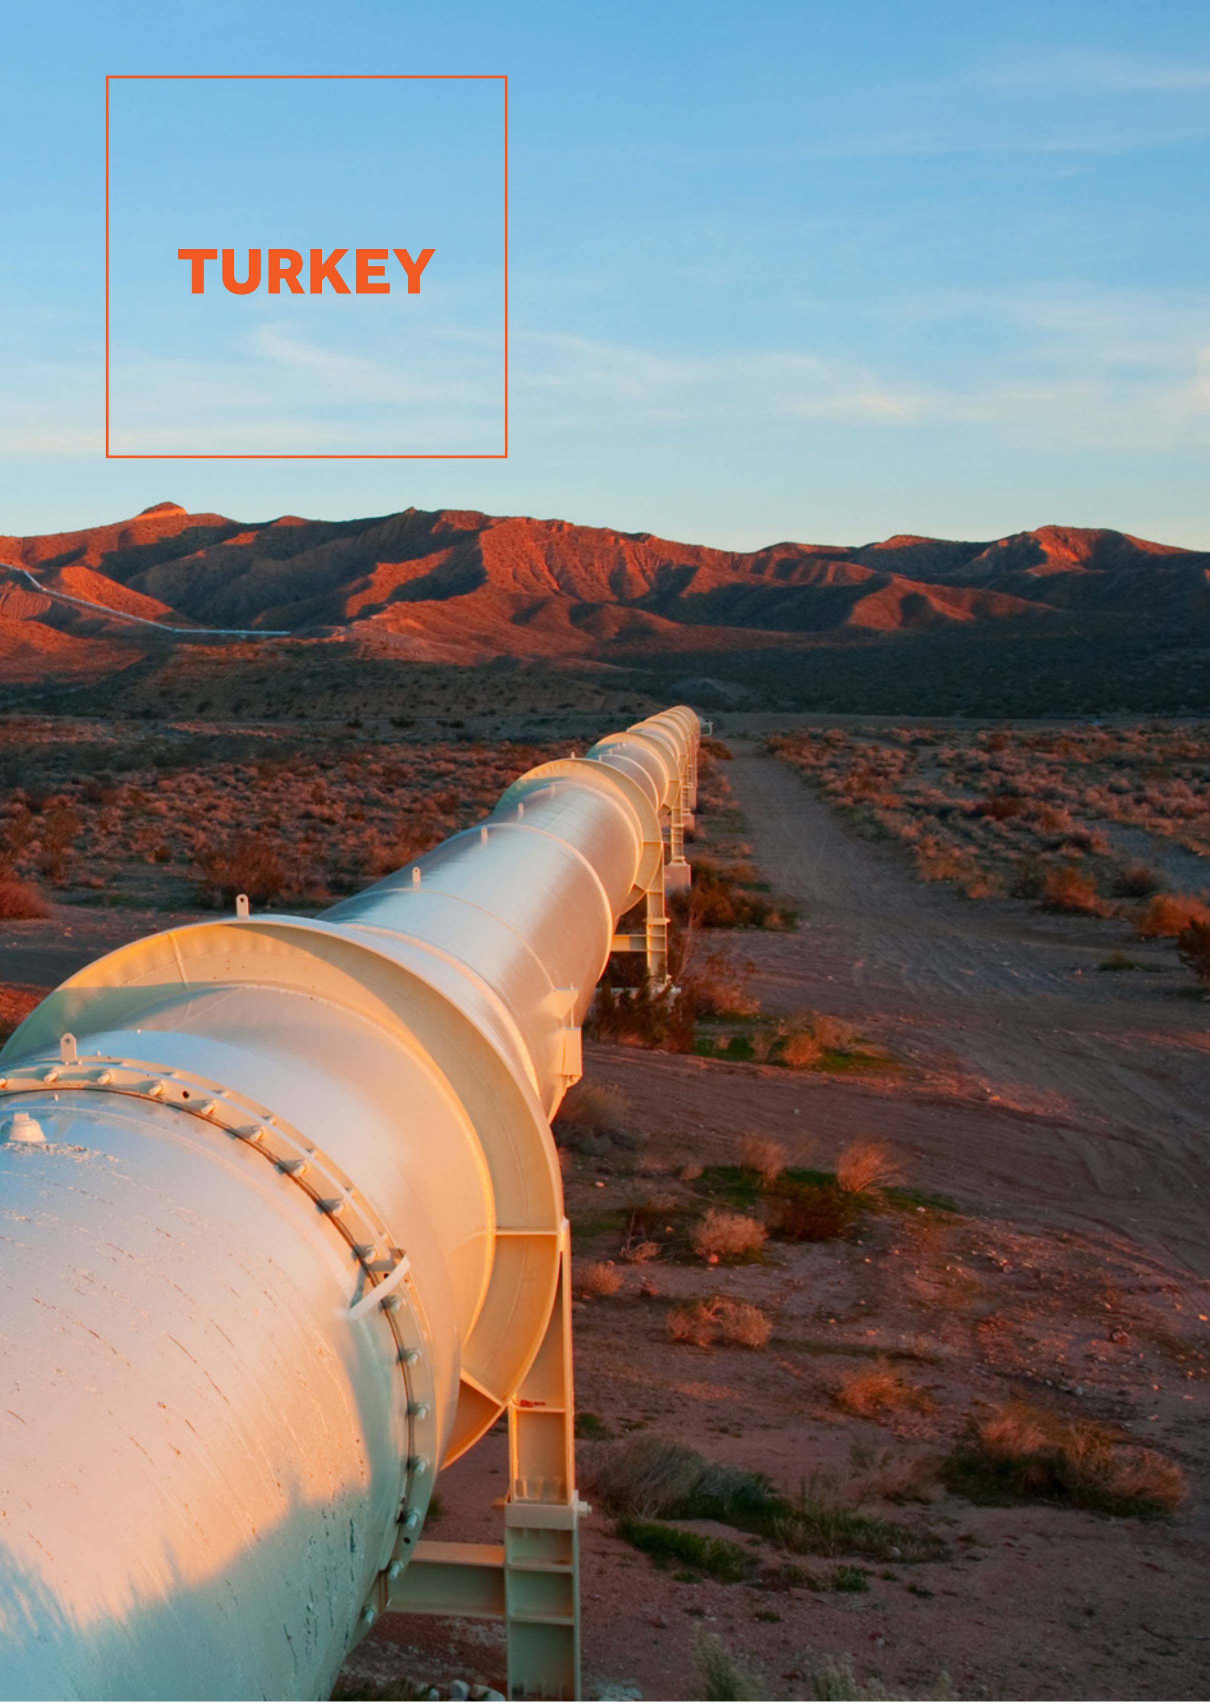
TURKEY



Turkey

Economic and Political Background

Turkey's GDP expanded 5.9% year-on-year in the fourth quarter of 2020, softening from the third quarter's 6.3% rise and coming in under market expectations. The reading was largely driven by slower growth in domestic demand and a persistent drag from the external sector. For the year as a whole, GDP rose 1.8% (2019: +0.9%). The Turkish economy was therefore one of the few in the world to achieve growth in 2020, despite pandemic-induced restrictions. However, IMF estimates that Turkey's GDP fell by 5.0% in 2020 and is expected to expand by 5.0% in 2021.

On the domestic front, household expenditure was the main driver of growth in the fourth quarter, thanks to a robust credit extension fomented by the government. That said, private consumption slowed amid the tightening of Covid-19 restrictions, growing 8.2% year-on-year in Q4 (Q3: +8.5% y-o-y). Moreover, capital spending growth slowed markedly to 10.3% in the quarter (Q3: +21.9% y-o-y). Meanwhile, public expenditure rose 6.6% in annual terms in Q4, after increasing 0.8% in Q3.

On the external front, exports of goods and services stagnated after collapsing in the previous quarter (Q4: +0.0% y-o-y; Q3: -22.1% y-o-y). Meanwhile, imports rose 2.5% annually in the fourth quarter (Q3: +16.4% y-o-y). On a seasonally-adjusted quarter-on-quarter basis, economic growth slowed to 1.7% in Q4 from the previous quarter's 15.9%.

Looking ahead, economic growth is expected to firm this year. Domestic and foreign demand is likely to strengthen as the country continues to ease restrictions and the global rollout of vaccines pushes forward, allowing more economies to reopen. Nevertheless, lira weakness and elevated inflation, coupled with uncertainty regarding the trajectory of the pandemic, will keep the outlook clouded.

President Erdogan won the June 2018 presidential elections in the first round, finally consolidating his power. With this vote, the transition to the new presidential system has been completed. In the June 2018 parliamentary elections, the alliance of Erdogan's AKP with the nationalist MHP party won 53.7% of the votes. In the March 2019 local elections, the AKP was again the party with the highest percentage in the vote, but the oppositional CHP won mayoral elections in several large cities. The next presidential and general elections are due to take place in June 2023. However, early general elections cannot be ruled out.

Domestic and regional political issues will continue to impact Turkey's economy, in particular investor sentiment and the exchange rate. The south-eastern part of the country remains affected by the civil war in Syria and cross-border interventions by the Turkish army. Over the past couple of years, Turkey has adopted an increasingly assertive foreign policy in order to establish itself as a leading power in the Mediterranean and the Middle East. Besides engagement and military incursions in Syria and Iraq, Ankara has set up a military base in Qatar, intervened in the civil war in Libya, supported the Azerbaijan forces in their armed conflict with Armenia, and sent gas exploration ships into contested areas in the Aegean Sea, where Turkey has overlapping maritime claims with Greece and the Republic of Cyprus.

Relations with the EU and the US remain strained, despite the fact that Ankara has recently attempted to ease tensions (e.g. resuming talks with Athens over overlapping claims and setting up a joint working group with Washington regarding US sanctions imposed over Ankara's purchase of Russian S-400 missile defence systems).

Energy Policy

(a) National Energy Policy

The main guidelines of the Turkish Energy Policy are the following: (a) 2023 Goals (released in 2010), (b) the National Renewable Energy Action Plan 2013-2023 (released in 2014), (c) the Ministry of Energy and Natural Resources (ETKB) Strategic Plan 2015-2019 (released in 2015) and (d) the 11th Development Plan (2019-2023). The main objective of Turkish energy policy is to provide the highest contribution to national welfare by supplying uninterrupted, sustainable, high quality, reliable and cost-effective energy from diversified sources in the most efficient and environmentally conscious manner (Strategic Plan 2015-2019).

In this regard the main priorities are highlighted below:

(i) Maximum utilization of renewable and indigenous sources,
(ii) Diversification of energy suppling countries and supply routes,
(iii) Reduction of energy intensity,
(iv) Introduction of nuclear energy into the energy mix,
(v) Reduction of environmental impacts of the energy system,
(vi) Development of a competitive energy market.

More specifically the following legal structure governs the implementation of above policies:

- Petroleum Law 6491 (2013) regulates the Exploration & Production of oil and gas.
- Petroleum Market Law 5015 (2003) regulates midstream and downstream activities in the oil sector.
- Mining Law 3213 (1985) and its amendments regulate the mining of solid fuels.
- Geothermal - Resources Law 5686 (2007) and its amendments regulate the exploration and extraction of geothermal resources.
- Electricity Market Law 4626 (2001) and its amendment 6446 (2013).
- Natural Gas Market Law (2001) and its amendments form the backbone of the energy market. They are supported by tens of regulations.
- Renewable Energy Law 5346 (2005) and its amendment 6094 (2011) support the electricity generation from renewable resources.

(b) Governmental institutions

After constitutional amendments of 2017 to the new presidential system, in 2018, some of the existing institutions were abolished and new ones were established.

Ministry of Energy and Natural Resources (ETKB) is still the main institution of the government to prepare and implement the energy policies of Turkey in cooperation with other relevant institutions and guided by the Development Plans.

General Directorate of Energy Affairs (EIGM) extended its duties as the main organ for policy development and implementation of ETKB. Its duties also include renewable energy promotion and deployment and the energy efficiency policies.

General Directorate of Renewable Energy (YEGM) responsible for renewable energy and energy efficiency policies has been abolished. Its duties were assigned to the EIGM.

BOTAŞ, established in 1973 to build and operate petroleum pipelines became in 1980's the natural gas monopoly. Despite the creation of the natural gas market in 2001 the state-owned company is still the largest trader and natural gas transmission system operator.

Turkish Electricity Transmission Company (TEİAŞ) is the Transmission System Operator of Turkey.

Electricity Generation Company (EÜAŞ) owns and operates the remaining generation assets of the state after the privatization and wholesales the electricity.

Turkish Electricity Trading Company TETAŞ, responsible for the wholesale of electricity bought from EÜAŞ and from the private generators in the framework of vested contracts of the pre-liberalization era, has been abolished in July 2018. Its responsibilities, including the purchase guaranty for electricity generated from Akkuyu nuclear power plant are transferred to EÜAŞ.

State Hydraulic Works DSI is responsible for the utilization of water resources.

Energy Exchange Istanbul (EPİAŞ) has been established in 2015. The shareholders are TEİAŞ (30%), Istanbul Stock Exchange (30%) and electricity and natural gas market participants (40%). After the unbundling of BOTAŞ, half of the TEİAŞ shares will be transferred to the natural gas transmission system operator.

General Directorate of Petroleum Affairs (PIGM) responsible for the regulation of exploration and production activities in the oil and gas sector was abolished. Its duties were transferred to the newly established General Directorate of Mining and Petroleum Affairs (MAPEG).

General Directorate of Mining and Petroleum Affairs (MAPEG) is responsible for licencing and supervision of exploration and production activities in mining and oil & gas industry since July 2018.

Turkish Atomic Energy Authority (TAEK) was the regulatory, research and radiation safety agency in nuclear field in Turkey. With the establishment of the Nuclear Regulatory Agency (NDK) in July 2018 all the regulatory activities were taken over by NDK. In March 2020, TAEK has been abolished and its remaining duties like nuclear research were transferred to the newly established TENMAK.
Turkish Energy Nuclear and Mining Research Agency (TENMAK), established on 28 March 2020 will be responsible for energy, nuclear, boron and rare earth elements research.

The Energy Market Regulatory Authority (EPDK) regulates the market activities in electricity natural gas, petroleum and liquefied petroleum gas markets.

Strategy and Budget Board (SBB) is the newly created agency of the new presidential system. SBB acts like the former State Planning Organization (DPT) in the field of economic and social planning and also took over some duties of the Ministry of Finance.

Competition Authority (RK) enforces the Law No. 4054 on Protection of Competition in cases of anticompetitive practices and has the responsibility to approve or dismiss mergers and acquisitions.

Energy Demand and Supply

a) National energy demand

Between 2013-2018 Turkey's total final energy consumption (TFC) increased 23.93% from 88.07 to 109.15 Mtoe (Table 5.243, Ministry of Energy and Natural Resources,2019). TFC in 2017 was the highest with 111.650 Mtoe and reduced in 2018 due to sluggish economy. Oil products have the largest share in TFC with 38.18%. The share of oil and electricity in TFC increased marginally between 2013-2018. Oil demand in the transport sector increased its share in TFC from 23.05% in 2013 to 25.49% in 2018. In the same period the share of natural gas in TFC increased substantially from 19.25% to 22.20%. The share of coal consumption was reduced from 16.14% to 12.55%.

b) National energy supply

Turkey's total primary energy supply increased from 116.3 Mtoe in 2013 to 145.3 Mtoe in 2017 but due to the economic problems reduced to 143.7 Mtoe in 2018 (Figure 5.294). In the 2013-2018 period total primary energy supply increased by 23.55%. We may observe an increase of the share of Wind+Solar+Geothermal from 3.5% to 8.1% and a decrease of the share of natural gas from 32.4% to 28.7% in the same period. The low share of Hydro with 3.58% in 2018 is the result of low water income and may increase in 2019 and in the following years.

Table 5.243 **Total final consumption TFC (Mtoe) and its sectoral breakdown in 2013 and 2018**

	Coal (1)	Oil (2)	N. gas	Electric.	Biofuels +waste (3)	Geoth. +Heat	Solar	Total

c) Energy balance

The energy balance of Turkey is shown in three tables (Tables 5.243-5.245). Table 5.243 shows the Total Final Consumption, Table 5.244 the Energy Supply, while Table 5.245 shows the Energy Transformation and Losses.

d) Energy Mix

In terms of Primary Energy Supply the energy mix of Turkey in 2018 was as follows: Coal (28.4%), Oil (29.2%) and Natural gas (28.7%) have nearly equal shares in Turkish energy supply in 2018. The sum of wind, solar and geothermal energy in 2018 was 8.1% more than double since 2013. In the same period the share of natural gas was reduced by 3.7%. Of the indigenous production of fossil fuels only coal has a substantial contribution to the energy mix. The share of local coal in energy supply was 11.5% in 2018. It should be further noted that the Turkish government is promoting the introduction of nuclear energy into the energy mix and investments in renewables in order to increase the share of indigenous resources.

Table 5.244 **Energy Supply of Turkey 2018 (Mtoe)**

	Coal (1)	Oil (2)	N. gas	Electric.	Bio +waste	Hydro	Wind	Geoth.	Solar	Total

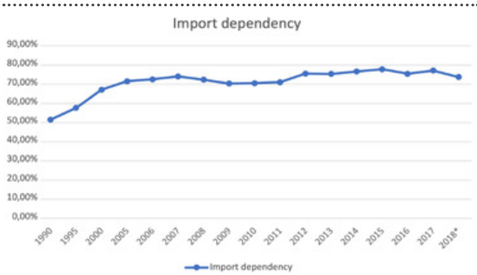
e) Energy Dependence

Over the last decades Turkey's energy import dependency grew from over 50% to over 70% and reached its highest level of 77.9% in 2015 (Figure 5.295). The result of the efforts to utilize local resources were rather modest. Many investment projects for new hydropower and coal capacities were mainly hindered by NGO resistance and a deteriorating investment climate.

Figure 5.295 **Turkey's energy import dependency 1990-2018 (%)**



Source: Eurostat, 2019 and Ministry of Energy and Natural Resources, 2019, (*)2018 figure may be subject to changes.

The Energy Market

(a) Oil supply and demand

The total final consumption of oil products increased from 33.425 Mtoe in 2013 to 41.681 Mtoe in 2018 by 24.7%. This is mainly due to the increased consumption in the transportation sector; the industry substituted part of its oil demand by using natural gas (Table 5.246).

Table 5.247 **Sectoral breakdown of total final consumption of oil in 2013 and 2018**

	2013		2018	
Sector	Mtoe	%	Mtoe	%
Industry	3.961	12	3.767	9
Transport	20.307	61	27.825	67
Other	9.017	27	9.734	24
Total Oil Products	33.425	100	41.681	100

Source: Ministry of Energy and Natural Resources, 2019

After three consecutive years of continuous growth, total petroleum product sales decreased by 2,30% to 27.807.223 tonnes in 2018 and the total refinery production decreased by 13,60% to 25.002.286 tonnes (Turkish Petroleum Market Report 2018, EPDK 2019). The demand increases for diesel, reported in previous SEE Energy Outlook 2015/16 continued in the years 2015-2017. Diesel consumption increased from 20.6 Mil t in 2015 to 24.2 Mil t in 2017 by 17.5%. Following the economic downturn in 2018, the diesel demand reduced to 23.6 Mil t by 2.4%. The decrease of gasoline demand reported in previous reporting period did not continue. Gasoline consumption increased from 2.1 Mil t in 2015 to 2.3 Mil t in 2018 by 11%.

(b) Oil imports

Turkey's main import items in the oil sector are crude oil and diesel. While crude oil imports decreased in 2018 by 18.6% due to economic slowdown to 20.9 Mill t, diesel imports increased slightly by 2.2% to 13.7 Mill t. With the new Star refinery in the west coast utilizing full capacity since August 2019 Turkey's crude oil imports have increased substantially. According to preliminary data for 2019 Turkey imported some 31.1 Mill t of crude oil.

Table 5.246 **Turkey's petroleum market, 2015-2018 (t)**

Production Type	Production				Import				Export				Domestic Sales(Consumption)				TOTAL DELIVERY

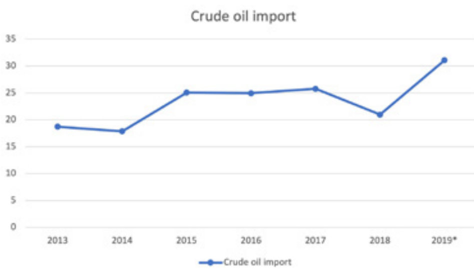
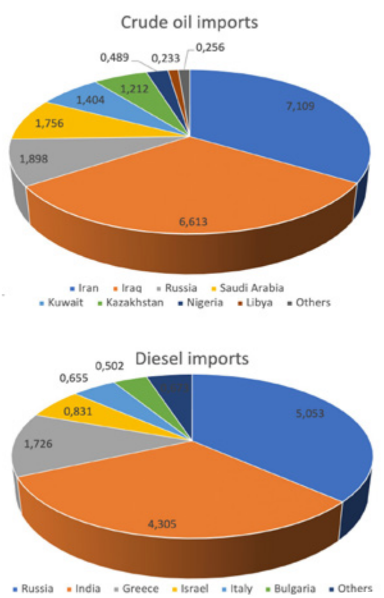
Figure 5.296 **Crude oil imports 2013-2019 (t)**



Source: Petroleum market reports 2013-2018, Petroleum market report December 2019, Energy Market Regulatory Authority EPDK.ges.

In 2018, the majority of crude oil imports were realized from Iran (33.9%) and from Iraq (31.5), followed by Russian Federation (9%), Saudi Arabia (8.4), Kuwait (6.7%) and Kazakhstan (5.8%). Diesel was imported mainly from Russian Federation (36.8%) and India (31.3%); followed by Greece (12.6%), Israel (6%) and other countries.

Figure 5.297 **Crude oil and diesel imports by country 2018 (Mill t)**

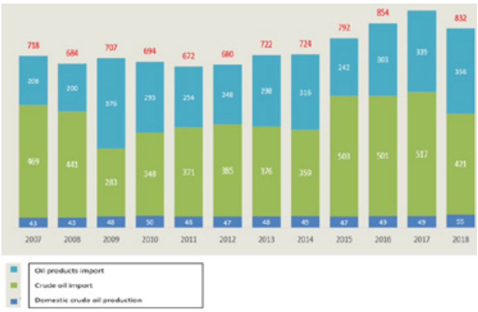


Source: Petroleum Market Report 2018, Energy Market Regulatory Authority EPDK, 2019.

After the US administration ended the sanction waivers, Turkey in July 2019 ceased importing crude oil from Iran. The gap was filled with increased imports from other countries.

According to preliminary figures the share of the Russian Federation has increased remarkably. Figure 5.298 shows Turkey's oil imports together and its local crude oil production.

Figure 5.298 **Oil imports and domestic crude oil production 2007-2018 (Thousand barrels per day)**

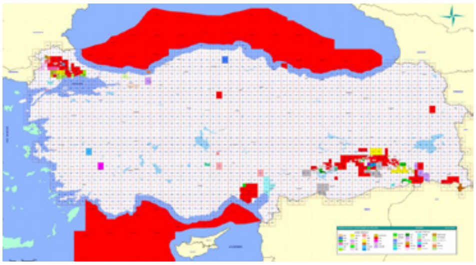


Source: TPAO Sectoral Report 2018, Turkish Petroleum Corporation, May 2019, EPDK Oil Market Reports, Energy Market Regulatory Authority

(c) Upstream sector - domestic production and exploration

Turkey's recoverable crude oil reserves in 2018 were 366 Mill barrels and without new discoveries the deposits will be depleted in 18 years. The oil is produced mainly in the Batman and Adiyaman basins in south-eastern Turkey and from old fields with declining well efficiency. The industry is extending its efforts for exploration of unconventional resources in Southeastern basins and for exploration in other basins. Off-shore exploration in the Black Sea and in the Mediterranean is also in focus. Map 5.71 shows hydrocarbon exploration and production licences held by companies.

Map 5.71 **Exploration and production licences in Turkey**



Source: MAPEG General Directorate for Mining and Petroleum Affairs, 2019. Areas in red colour indicate TPAO licences.

In 2018, a total of 157 licences were active and 107 wells (67 by Turkish Petroleum Corporation TPAO and 38 by other companies) were drilled. 51 of them were exploration wells and the remaining 56 production wells (Sector report 2018, TPAO 2019). Since 2012, TPAO intensified its offshore exploration activities both in Black Sea and Mediterranean. The crude oil production of Turkey exceeded for the first time in 1968 the 3 Mill t mark, but this level could not be maintained in the following decades. After decreasing to 2.134 Mill t in 2007, the production reached the highest level of the last 20 years in 2018 with 2.851 Mill t. Approximately 67% of the production was realized by TPAO. Figure 5.299 shows the development of crude oil production in Turkey during the last 20 years.

Figure 5.299 **Crude oil production in Turkey, 1999-2018**

Latest Major discovery in the Black Sea

According to an announcement on August 21 by Turkey's president Recep Tayyip Erdogan a major gas field has been discovered in the Turkish section of the Black Sea. Hailing the find Turkey's president said that " this is a historic step" for the country's troubled economy and its energy security. Presenting details of this latest energy find, Mr. Erdogan said that following exploration activity by TPAO, the state-owned petroleum company, a 320 by cubic metres gas deposit had been found.

The deposit was identified following extensive seismic research and exploration drilling some 145 kms offshore from the town of Zonguldak in the Black Sea.

The precise drilling location known as Tuna 1 is located very near the well-known Polshkov and Andrusen geological ridges, and neighbours other major finds such as the Neptun and Skifska reservoirs in the Romanian and Ukrainian sectors respectively. The size of the field, that needs to be confirmed with additional appraisal drilling, would be approximately 40% as large as Egypt's supergiant Zohr field which is offshore in the Nile delta in Egypt and has been producing since 2017. In October, 2020 Tuna 1 well reached a total depth of 4,775 m and encountered an additional 30 m gas-bearing reservoir in Early Pliocene-Late Miocene sands and raised estimated gas potential to 405 (Oil&Gas Journal, Oct 19, 2020). "As a country that has suffered problems for years as a result of our dependence on foreign energy sources, I believe that we can now look to the future in greater confidence", Mr Erdogan observed.

Map 5.72 **Turkey's latest gas discovery in the Black Sea**

A detailed analysis of this new discovery by Turkey in the Black Sea and the potentially huge implications that this find is bound to have for the country's energy supplies, the strengthening of its energy base and for its economy is currently being prepared by IENE's team and will be released early in September.

(d) Downstream and midstream sectors infrastructure (Refineries, Pipelines, Storage, Terminal and Domestic Oil Market)

After the shutdown of the Ataş refinery in Mersin in the Mediterranean coast in 2004, Turkey was lacking refining capacity to satisfy increasing local demand for fuels. In 2018, Turkey had four refineries in operation with a total crude refining capacity of 30 mill t/year all belonging to TÜPRAŞ of the Koç Group.

Izmit refinery, 70 km east of Istanbul, established in 1961 has a refining capacity of 11.3 mill t/year and serves Istanbul and the region around Marmara Sea. İzmit Refinery has one of the highest conversion rates in the world, with a Nelson Complexity value of 14.5 (TÜPRAŞ, 2020).

Izmir refinery located in Aliağa 60 km north of Izmir with 11.9 mill t/year refining capacity supplies the western regions of Turkey. İzmir refinery has a 7.66 Nelson Complexity. In 2018 a total of 9.7 million tons of raw materials, including 9.4 million tons of crude oil and the remainder being semi-finished products was processed in İzmir Refinery (TÜPRAŞ, 2020).

Kırıkkale refinery located 80 km east of Ankara has a capacity of 5.4 mill t/year and serves the central and eastern provinces of the country. The refinery receives crude oil via pipeline from the Mediterranean harbour of Ceyhan. To distribute oil products, Kırıkkale refinery has Turkey's largest road tanker filling capacity (TÜPRAŞ, 2020).

Batman refinery is located in Southeast Turkey, close to the crude oil producing basins and has a capacity of 1.4 mill t/year. The refinery with a Nelson complexity of 1.83 has no upgrading units and is processing heavy crude oil from domestic fields of the region (TÜPRAŞ, 2020). The fifth and newest refinery in Turkey is the STAR refinery, commissioned at the end of 2018. The STAR refinery is located just 4 km south of the Izmir refinery of TÜPRAŞ and belongs to SOCAR from Azerbaijan. In August 2019 the STAR refinery reached its planned capacity of 10 mill t/year. STAR refinery will produce 4.8 mill t/year diesel, 1.6 mill t/year aviation fuel, 0.7 mill t/year Petroleum coke and 0.3 mill t/year LPG mainly destined for the domestic fuel market. The STAR refinery will also supply the PETKIM petrochemical complex of SOCAR on the same site with 1.6 mill t/year Naphtha, 0.4 mill t/year Xylene and 0.5 mill t/year Reformat (SOCAR, 2020). Table 5.248 shows the processing capacities of TÜPRAŞ and STAR refineries and market demand.

Table 5.248 **Refinery capacities and oil products demand**

Turkey Demand	Tüpraş	STAR	Total	Turkish Market Demand	Balance
LPG	1.1	0.3	1.4	4.1	-2.7

Total	~30	~10	~40		

Source: TÜPRAŞ Investor Presentation, March 2020

In 2018, the domestic petroleum market was supplied by 97 distributors and 12,828 fuel stations and the Liquified Petroleum Gas (LPG) market was supplied by 92 distributors and 10,701 autogas stations (PETDER 2018 Sector report, Petroleum Industry Association, 2019). The four largest distributors in the petroleum market (POAŞ, OPET, SHELL, BP) account for 65.6% of the sales and the ten largest for 84.6%. According to analyses at taking into consideration Concentration and Herfindahl-Hirschman Indexes, the petroleum market is in competition but has a tendency to shift to an oligopoly structure (Turkish Petroleum Market Report 2018, EPDK 2019). In latest proceedings the Turkish Competition Board ruled against four companies because of breach of the Competition Law Article 4. According to the Board's decision these companies have to pay 1% of their gross income of 2018 as a fine (Bloomberg.com, 13 March 2020). The oil companies are taking legal action against the decision of the Competition Board.

The Turkish petroleum market prices follow the prices published on the Platts European Market Scan; the changes are reflected not on daily basis but according to a certain formula. The final retail price includes the product price, wholesale margin, income share, distributer and dealer share and taxes. The retail prices differ geographically according to the transportation distances. Table 5.249 shows the components of the final sales price in 2018 in Istanbul's European side.

Table 5.249 **Formation of the average gasoline and diesel prices in 2018 in Istanbul**

		Product Price	Wholesale Margin	Income Share	Distributer, Dealer Margin	Taxes	Final Sales Price
Unleaded 95 Octane	TL/l	2.445	0.077	0.003	0.536	3.158	6.219
	Share	39.31%	1.24%	0.05%	8.62%	50.78%	100%
Diesel	TL/l	2.66	0.037	0.003	0.552	2.549	5.701
	Share	46.66%	0.65%	0.06%	9.68%	42.95%	100%

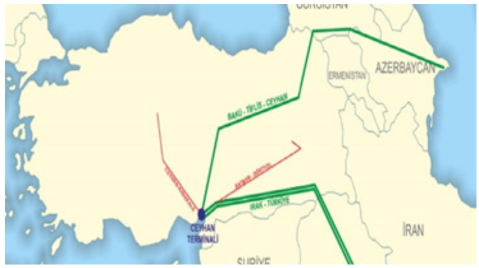
Source: Turkish Petroleum Market Report 2018, EPDK 2019

BOTAŞ and its affiliate BIL operate two domestic and two international crude oil pipelines in Turkey (Map 5.73). The oldest is Batman-Dörtyol pipeline with 4.5 mill t/year capacity, running 511 km from the oilfields of southeast Turkey to the Mediterranean Terminal in Dörtyol. Ceyhan-Kırıkkale pipeline with a capacity of 7.2 mil t/y supplies since 1986 the Kırıkkale refinery with crude oil. The pipeline transported in 2018 4.270 mil t and in 2019 some 4.766 mil t (Botaş, 2020).

The Iraq-Turkey crude oil pipeline was inaugurated in 1976 and the initial capacity of 35 mill t/year was increased in 1984 to 48.6 mill t. With the commissioning of a second line in 1987 the capacity reached 70.9 mill t/year. The pipelines run from the oil fields in Northern Iraq to the Mediterranean harbour of Ceyhan. Since the Gulf War and the UN embargos in 1990's, these pipelines are used in reduced capacity and some sections are damaged. In 2018 the Iraq-Turkey pipeline transported 18.371 mil t and in 2019 some 26.478 mil t to Ceyhan Terminal (Botaş, 2020).

The 1776 km long BTC pipeline stretching from the Sangachal Terminal in the Caspian Sea in Azerbaijan via Georgia to Ceyhan Terminal in Turkey was inaugurated in 2006. The pipeline transports crude oil from ACG fields, condensates from Shah Deniz field and other crude from the Caspian basin. It has a capacity of 50 mil t/year and in 2018 supplied the Ceyhan Terminal with 34.894 mil t and in 2019 with 32.093 mil t (BOTAŞ, 2020).

Map 5.73 **Crude oil pipelines of Turkey**



Source: Ministry of Energy and Natural Resources ETKB, 2020.

During the last years TÜPRAŞ made substantial investments in the development of its transportation fleet. TÜPRAŞ affiliate DITAŞ owns 13 tankers for crude oil and oil products transport. The railway company Körfez Ulaştırma, also a subsidiary of TÜPRAŞ carried with 10 locomotives and 600 cistern wagons 1.8 mil t of products and semi-products in 2019 (TÜPRAŞ Investor Presentation 2020).

(e) Security of supply (+Storage)

Since 1970's Turkey is trying to diversify the oil imports. Realization of Iraq-Turkey crude oil pipeline was an important step in this regard. As an IEA member country Turkey has an obligation to hold emergency oil stocks at least for 90 days of net oil imports. The level of oil stocks is reported monthly to the IEA. Turkey meets its stockholding requirements in the form of "Obligated Industry Stocks" held by the oil industry. Turkey also uses an "Oil Stock Ticket" system, where companies can buy tickets to cover their stockholding obligations from a company holding stocks in excess (International Energy Agency, Energy Market Regulatory Authority, 2020). The oil storage capacity of Turkey is over 15 mill cubic meters. While the majority of stocks are held by refineries, the four refineries of TÜPRAŞ have a total stockholding capacity of over 7 mil cubic meter. The new Star refinery has 1.6 mill t storage capacity. Former ATAŞ refinery near Mersin at the Mediterranean has been transformed into an oil products terminal and serves with a capacity of 577.000 cubic meters as a licensed storage facility (TURCAS, 2020). RUBIS oil terminal in Dörtyol is located close to BOTAŞ Dörtyol facilities and has 650.000 cubic meter storage capacity (RUBIS,2020). Distribution market leader POAŞ and the second largest distributer OPET have 1 mil cubic meters and 1.1 mil cubic meters storage capacity respectively. There are several other storage facilities with smaller capacities.

(f) Planned new projects

Upstream investments will focus on increasing well efficiency in old fields, horizontal drillings of potential unconventional resources in South-eastern Turkey and exploration in untapped regions. Following the discovery in August 2020 of a new major field in the Black Sea, considerable attention will now be given in the drilling of appraisal and development wells and the preparation of the production programme.

The refinery project of Çalık Holding in Ceyhan in the Mediterranean coast unveiled in 2006 has not been realized. At the end of 2016, Turkey's Wealth Fund announced a plan to invest 10 bill $ in a new refinery and petrochemical facilities in Ceyhan. The investment should start after the finalization of the preliminary studies in 2021 (Turkchem, Jan 2020).

There are no new oil pipeline projects in planning.

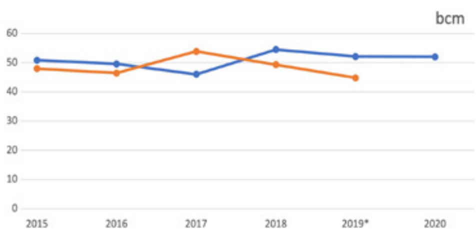
In a second phase of investment Star refinery will increase its initial 1.6 mill t storage capacity to 2.5 mill t until 2021. The storage capacity of 650.000 cubic meter at the RUBIS oil terminal in Dörtyol is planned to be increased to 1 mil cubic meter (RUBIS,2020). TPAO announced a new investment in Batman to add 23,850 cubic meters crude oil storage capacity to the existing 38,478 cubic meters.

Natural Gas

(a) NG Supply and Demand

In 2018, natural gas consumption in Turkey decreased to 49.329 bcm from 53.857 bcm in 2017 by 8.41%. According to preliminary figures the consumption decreased again in 2019 to the level of 44.794 bcm, ie by 9.2% compared to 2018 (EPDK). During 2015-2019 the realized consumption was lower than the yearly forecasts of the Energy Market Regulatory Authority except 2017 (Figure 5.300).

Figure 5.300 **Natural gas consumption forecasts realization for the period 2015-2020**



Source: Energy Market Regulatory Authority, (*) 2019 realization is a preliminary figure subject to change.

Negative economic conditions in the second half of 2018 and the first three quarters of 2019 may be the reason for reduced natural gas consumption, but in 2019 the effects of the mild winter and high electricity generation from renewables and hydropower plants were also accountable. Table 5.250 shows the sectoral breakdown of consumption between 2015-2018.

Table 5.250 **Sectoral breakdown of natural gas consumption in Turkey (bcm)**

	2015	2016	2017	2018
Energy&Conversion	19.313	18.493	22.593	19.933
Industry	13.966	12.600	13.372	11.988
Residential	11.000	11.701	13.515	12.702
Services	3.161	3.123	3.726	4.043
Transport	0.423	0.457	0.529	0.431
Others	0.137	0.107	0.122	0.233
Total	47.999	46.481	53.857	49.329

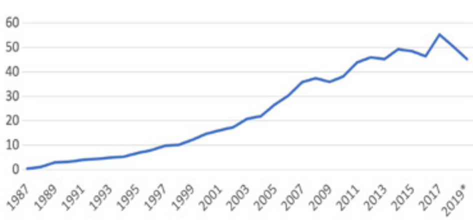
Source: Turkish Natural Gas Market Report 2016, 2017, 2018, Energy Market Regulatory Authority.

In 2018, the Energy & Conversion sector consumed 40% of the natural gas followed by the Household (26%) and Industry (24%) sectors. As the gas distribution network expanded to remote cities of the country the share of the residential consumption surpassed that of industry in recent years.

(b) NG Imports

Turkey's natural gas imports were increasing continuously for 21 years in the period 1987-2008. After that, the upward trend continued, with some fluctuations. The highest level of imports was achieved in 2017 with 55.250 bcm. In 2018, the imports reduced to 50.360 bcm by 8.8%. According to preliminary figures the imports were reduced again in 2019 to 45.207 bcm by 10.2% (Figure 5.301). As mentioned above, the latest decline in 2019 was caused not only by the sluggish economy but also by the weather conditions and historically high generation from hydro and renewables reaching a 44% share of in electricity generation.

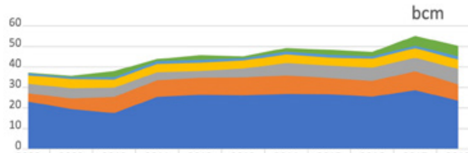
Figure 5.301 **Natural gas imports 1987-2019 (bcm)**



Source: BOTAŞ, Energy Market Regulatory Authority, (*) Preliminary figure may subject to change.

Turkey's main natural gas supplier is the Russian Federation with a share of 47% in 2018 followed by Iran 16% and Azerbaijan 15% (Figure 5.302). All three countries supply their gas by pipelines. The main LNG suppliers of Turkey with long term contracts include Algeria and Nigeria and in 2018 they had a share of 9% and 3% respectively of total gas imports to Turkey. The remaining 10% of supply came in 2018 from spot LNG purchases from eleven countries.

Figure 5.302 **Natural gas imports by country**



2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018

Russia Iran Azerbaijan Algeria Nigeria Spot LNG

Source: Turkish Natural Gas Market Report 2018, Energy Market Regulatory Authority, 2019.

90% of Turkish natural gas imports were realized in the framework of long-term contracts from those five countries as shown in Figure 5.302. According to the Natural Gas Market Law BOTAŞ transferred 4 bcm of its Gazprom contract ending in 2022 to four private importers.

Table 5.251 **Turkey's long-term natural gas import contracts**

Country	Importer	Volume (bcm/a)	Duration (years)	Start /End
Algeria LNG	BOTAŞ	4.4	30	1994/2024
Nigeria LNG	BOTAŞ	1.3	22	1999/2021
Russia (Balkan)*	BOTAŞ	4.0	23	1998/2022
Russia (Balkan)*	Other (**)	4.0	23	1998/2022
Iran	BOTAŞ	9.6	25	2001/2026
Russia (BlueStream)	BOTAŞ	16.0	25	2003/2028
Azerbaijan I	BOTAŞ	6.6	15	2007/2022
Russia (Balkan)*	Other (***)	1.0	23	2013/2036

Azerbaijan II	BOTAŞ (*****)	6.0	15	2018/2033
Total		**57.9**		

Source: BOTAŞ, GAZID Natural Gas Importers Association.

* Since Jan 2020 via TurkStream,

** Contract transfer from BOTAŞ: 2.5 bcm Enerco, 0.75 bcm BosphorusGaz, 0.5 bcm Avrasya, 0.25 bcm Shell,

*** Batı Hattı,

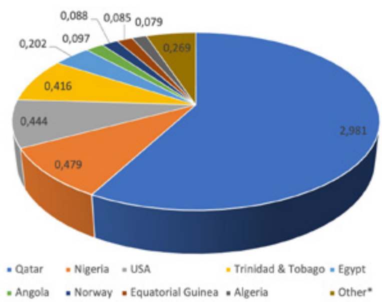
**** 2.25 bcm Akfel, 1.75 bcm BoshorusGaz, 1 bcm Kibar,

***** 1.2 bcm imported by BOTAŞ for SOCAR.

BOTAŞ also did not extend its 6 bcm per year Gazprom contract which ended in 2011. Meanwhile, four private importers signed new contracts of 1+5 bcm ending in 2036 and 2043 respectively.

In 2018, 77.5% of gas imports were via pipeline gas and 22.5% via LNG. In 2017 Turkey became the second largest LNG importer in Europe after Spain. Spot LNG imports to Turkey have grown remarkably over the past years. Table 5.251 shows the distribution of 5.140 bcm spot LNG imports by country of origin in 2018.

Figure 5.303 **Spot LNG imports by country (bcm)**



Source: Turkish Natural Gas Market Report, 2018, Energy Market Regulatory Authority. (*) Re-exports from France and Spain.

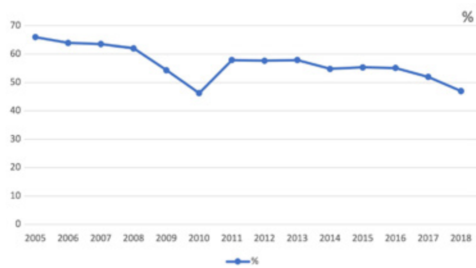
Qatar had the largest share with 58% in spot LNG imports in 2018 followed by Nigeria 9.3%, USA 8.6% and Trinidad and Tobago 8.1%.

In 2007, Turkey started to export Azerbaijani natural gas in the framework of a 0.75 bcm Long-Term Sales Agreement to Greece. After the build-up period 2007-2008 the exports swung around the plateau figure and reached 0.685 bcm in 2018 and 0.776 bcm in 2019. It should be noted that Greece's DEPA has a long-term contract with BOTAS for the import of this gas, which is now characterised as "Turkish Basket" rather than Azeri gas.

(c) Dependence

Despite all the diversification efforts, Turkey is still highly dependent on natural gas imports from the Russian Federation (Figure 5.304). Immediately after the start of natural gas imports from USSR in 1987, Turkey reinforced its diversification efforts by signing long term LNG supply contracts with Algeria and Nigeria and erecting the first LNG regasification terminal in Marmara Ereğlisi. Hence, its 100% dependence on Russian gas was reduced with the first LNG delivery from Algeria in 1994 and from Nigeria in 1999. Despite Turkey starting to receive pipeline gas from Iran in 2001 and from Azerbaijan in 2007, the share of supplies from Russian Federation are still high and account for 66% in 2005. This share has now (2018) been diluted to 47% following the increased spot LNG imports in 2017 and 2018 (see Figure 5.304).

Figure 5.304 **The share of Russian Federation in total natural gas imports**

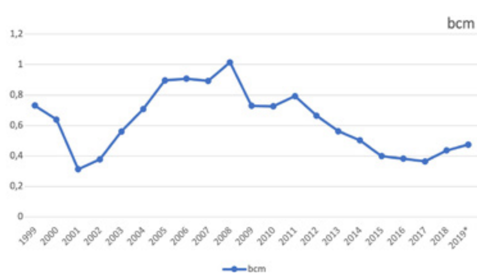


Source: Natural Gas Market 2010 Sectoral Report, Turkish Natural Gas Market Report 2018, EPDK.

(d) Domestic Production and Exploration

Domestic natural gas production reached its highest level in 2008 with 1.015 bcm. In 2018, some 0.436 bcm production covered less than one percent of the country's demand (Figure 5.305).

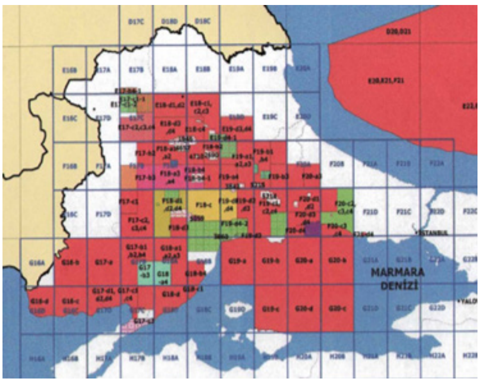
Figure 5.305 **Turkey's domestic natural gas production 1999-2019**



Source: MAPEG, 2019; Natural Gas Market Monthly Report December 2019, EPDK 2020.

Turkey's recoverable natural gas reserves were 3.8 bill cubic meters in 2018; 51% of those reserves belong to the Turkish Petroleum Corporation (TPAO) and the remaining 49% to other natural gas producing companies (MAPEG). It should be pointed out that 98% of the indigenous natural gas has been produced from onshore fields and only 2% from a shallow depth offshore field in the Black Sea coast near Akçakoca. 97.5% of the production comes from Thrace Basin fields in the European part of Turkey (Map 5.74). In 2018, 10 companies holding wholesale licences from EPDK were conducting natural gas exploration and production activities in Turkey. According to EPDK, the largest producer was TPAO with 74.5% followed by Thrace Basin Natural Gas Corporation with 12.3% and Marsa Turkey with 10.2%. According to its latest report, TPAO produced 0.405 bill cubic meters of natural gas in 2018.

Map 5.74 **Exploration and Production licences of the Thrace Basin**



Source: MAPEG

A joint venture formed by Equinor of Norway and Valeura Energy of Canada to explore formations deeper than 2,500 m in Banarlı and West Thrace licence areas drilled their first deep exploration well Yamalık-1, a gas and condensate discovery (Map 5.74). The joint venture partners announced a potential of 286 mcm yet to be proved with appraisal tests. In February 2020 it was announced that Equinor will stop participating in the appraisal program and Valeura will continue (Alliance News, 4 February 2020).

Map 5.75 **Exploration areas of the Equinor-Valeura Energy joint venture**

Source: www.equinor.com

In March 2020, TPAO discovered in the Thrace Basin some 200 mcm natural gas in 2 wells (Daily Sabah, 12 March 2020). Next to the Thrace Basin, TPAO will focus in offshore exploration in its licence areas (shown in red colour) in the Black Sea and in the Mediterranean. In 2018, TPAO conducted two offshore drillings at Kuzey Erdemli-1 shallow water and Alanya-1 deep sea wells in the Mediterranean. Also, it is important to note that in August 2020 a major gas discovery was announced in the Black Sea which is yet to be fully appraised, but apparently is quite sizable and capable of covering a substantial part of Turkey's gas needs over the next 15-20 years.

(e) Infrastructure (Pipelines, Storage)

In 2018 the length of the natural gas transmission grid reached 15,547 km and the distribution network 137,535 km (BOTAŞ, 2018 Natural Gas Distribution Sector Report, Natural Gas Distribution Companies

Association of Turkey GAZBIR 2019). Map 5.76 shows the extensive gas transmission pipeline system of Turkey.

Map 5.76 **Natural gas transmission system of Turkey**

The first international natural gas pipeline connection of Turkey, the **Russia-Turkey Trans-Balkan Pipeline** with an initial capacity of 6 bcm/year was inaugurated in 1987 and runs 845 km from the Bulgarian border via Istanbul, Izmit, Bursa and Eskişehir to Ankara. To allow additional supplies, the capacity of the metering station at the entry point Malkoçlar was increased from 8 to 14 bcm/year parallel to the capacity increase of the pipeline. The line has three compressor stations in Kırklareli, Ambarlı and Eskişehir. After completion of the TurkStream pipeline and its operation in January 2020 Gazprom ceased to supply this line.

The **Blue Stream Pipeline** with 16 bcm/year capacity became operational in 2003 and runs 370 km from Izobilnoye to Djubga onshore in the Russian Federation and 390 km offshore in the Black Sea. In Turkey it continues from the Durusu metering station near Samsun, 501 km via Amasya, Çorum and Kırıkkale to Ankara. The line has one compressor station in Çorum.

The **Iran-Turkey (Eastern Anatolia) Pipeline** with 10 bcm/year capacity has been operational since 2001. It has a length of 1491 km in Turkey from Gürbulak border crossing via Erzurum, Sivas, Kayseri to Ankara. The line has four compressor stations in Doğubayazıt, Erzincan, Sivas and Kırşehir. The measuring station is in Bazargan on the Iranian side of the border.

The **Baku-Tbilisi- Erzurum Pipeline** with an initial capacity of 7 bcm/year became operational in 2007. The 690 km long (South Caucasus Pipeline) is connected with a 226 km stretch from the Georgian border to Erzurum to the Turkish transmission system. There is a metering station at the entry side in Türkgözü and a compressor station in Hanak near Ardahan.

The **Interconnector Turkey-Greece ITG** with a length of 296 km connects the Turkish and Greek transmission networks between Karacabey and Komotini. The pipeline has a capacity of 7 bcm/year and has been in operation since 2007.

The **Trans-Anatolia Pipeline TANAP** with a capacity of 16 bcm/year stretches 1850 km from the Georgian border to the Greek border. It will supply natural gas from Shah Deniz Phase II field to Turkey and other European countries. At the Georgian border it is connected to the extended South Caucasus Pipeline and at the Greek border to the Trans-Adriatic Pipeline TAP. TANAP has two metering stations at the borders and two at the off-take points in Eskişehir and in Thrace. Two compressor stations have been erected near the entry point at the east and at the off-take point in Eskişehir. The pipeline supplied first gas to the Turkish grid in June 2018 and was connected to TAP in November 2019.

The **TurkStream Pipeline** is Turkey's latest major gas pipeline and starts at the Russkaya compressor station near Anapa on the Russian coast and runs over 930 km underwater in the Black Sea to reach the Turkish coast at Kıyıköy northwest of Istanbul. TurkStream consists of two strings each with 15.75 bcm/year capacity. One line is connected to the Turkish grid in Lüleburgaz and delivers the gas previously coming through the Trans-Balkan Line, to Turkey's domestic market since January 2020. The second line is planned to supply South and Central Europe with Russian gas via Bulgaria, Serbia and Hungary. Bulgaria, Greece and North Macedonia are receiving gas from TurkStream since the beginning of January 2020.

Map 5.77 **Natural gas import and export infrastructure of Turkey**

Source: BOTAŞ, revised. UGS: Underground storage facility, LNG: Liquified natural gas regasification terminal, FSRU: Floating storage and regasification terminal.

Turkey's first LNG regasification terminal at Marmara Ereğlisi west of Istanbul owned by BOTAŞ received its first cargo in 1994. After the extension of its jetty in 2019, the terminal received the first Q-Flex LNG carrier (LNG World News, 18 June 2019). In late 2006, private sector investment of the Çolakoğlu Group, EgeGaz LNG regasification terminal in Aliağa north of Izmir went into service. The Egegaz terminal may receive up to Q-Max class LNG vessels. Turkey's LNG infrastructure is summarized in Table 5.252.

Table 5.252 **Turkey's liquified natural gas import infrastructure**

Terminal	Type	Capacity (bcm/year)	Storage capacity (cubic meters)	Send out capacity (mcm/d)
Botaş Marmara Ereğlisi	Onshore LNG	6.0	255,000	37
Egegaz Aliağa	Onshore LNG	6.0	280,000	40
Etki Aliağa	FSRU	5.3	170,000	28
Botaş Dörtyol	FSRU	5.3	263,000	20
Botaş Saros	FSRU	under implementation		

Source: BOTAŞ, Egegaz, Etki FSRU.

The Etki Aliağa FSRU terminal is owned by private sector companies Kalyon (50%), Kolin (30%) and the Iska Group (20%) and started its operation in December 2016 with the chartered FSRU Neptune (former GDF Suez Neptune). In July 2019 the new FSRU Turquoise P with 170,000 cubic meters storage capacity, ordered by the owners of the terminal and built at the Ulsan shipyard of Hyundai in South Korea replaced Neptune. BOTAŞ Dörtyol terminal started its operation in February 2018 with the chartered MOL FSRU Challenger with 263,000 cubic meter capacity.

The Turkish government makes enormous efforts to increase the country's natural gas storage capacities to 11bcm by the year 2023. The first underground storage facility of Turkey is the BOTAŞ Silivri facility and is using the depleted natural gas fields of TPAO in northern Marmara Sea and Değirmenköy. The facility started its commercial operation in 2007 and reached a working gas storage capacity of 2.8 bcm with Phase II investments (Table 5.253). After the commissioning of the third phase investment the capacity will increase to 4.6 bcm. Tuz Gölü underground storage facility is located near Sultanhani in central Turkey.

The facility is using salt caverns in 1100-1400 m depth created by solution mining. The first phase of the project was completed in

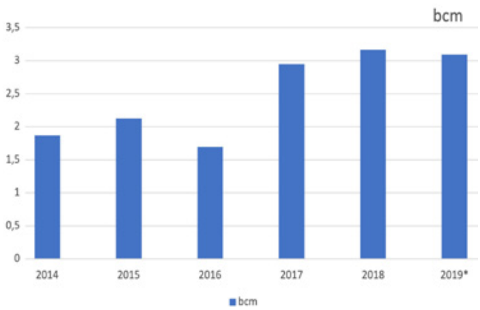
February 2017. With the ongoing second phase investment the storage capacity will increase to 5.4 bcm. The other two envisaged projects are also planned to be implemented in salt domes in the Tarsus area near the Mediterranean Sea and in the Tuz Gölü area, but there is no progress reported as yet.

Table 5.253 **Turkey's underground gas storage capacity**

Location	Capacity (bcm)	Injection rate (mcm/d)	Withdrawal rate (mcm/d)
Operational			
Botaş Silivri Phase II	2.8	16	25
Botaş Tuz Gölü Phase I	0.6	30	20
Under Implementation			
Botaş Silivri Phase III	4.6	40	75
Botaş Tuz Gölü Phase II	5.4	60	80
Planning			
Toren Tarsus Phase I	0.5		24
Çalık Tuz Gölü	1.0	10	20

Turkey's underground storage capacity reached 3.291 bcm in 2018. The LNG storage capacity increased from 0.943 bcm in 2018 to 0.968 bcm in 2019. The year-end natural gas stock in 2018 was 3.167 bcm and in 2019 it reached 3.095 bcm as shown in Fig. 5.306.

Figure 5.306 **End of the year natural gas stock**



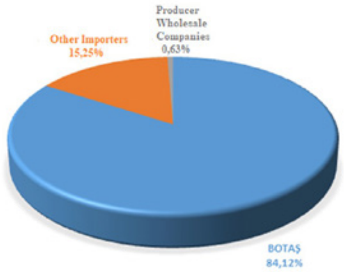
Source: Energy Market Regulatory Authority. (*) Preliminary figure, subject to change.

In 2018, the volume of the stored natural gas in the pipeline system was swinging around 0.250-0.380 bcm (Turkish Natural Gas Market Report 2018, EPDK 2019).

(f) Domestic Gas Market

The basic goals of the Natural Gas Market Law No.4646 of 2001 which are to create competition and avoid dominant market structures have not been achieved yet. The law abolished BOTAŞ's monopoly rights on imports, distribution, sales and pricing. Account separation for trade, transmission and storage was realized. However, an autonomous TSO has not been established yet. BOTAŞ is at the same time TSO and the dominant player in the natural gas market. In 2018, some 84.12% of 50.789 bcm total supply was realized by BOTAŞ. Some 15.25% was realised by other importers and 0.63% by domestic gas producing wholesale companies (Figure 5.307). The wholesale activities are conducted by import licence and wholesale licence holding companies. By the end of 2018 there were 54 companies with a wholesale licence and 11 of them were domestic natural gas producers. In 2018, eight (8) companies with Import licence conducted wholesale activities. Those are BOTAŞ, Shell, Avrasya Gaz, Enerco, Kibar, Batı Hattı, Akfel and BosphorusGaz. From 47 Spot LNG Licence holders 16 realized wholesale activities and only two, BOTAŞ and Egegaz imported spot LNG. The remaining traded with domestic gas.

Figure 5.307 **Share of importers and domestic natural gas producers in total gas supply in 2018**



Source: Turkish Natural Gas Market Report 2018, Energy Market Regulatory Authority, 2019.

After the publication of the Regulation on Wholesale Natural Gas Market in March 2017 and its Operating Procedures and Principles in September 2019 in the Official Gazette, online testing of the Spot Natural Gas Trade System was launched on 1 April 2018. On 1 September 2018, Organized Wholesale Natural Gas Market OTSP at the Energy Exchange in Istanbul (EPİAŞ) started. OTSP allows the users of the

5

natural gas transmission system to trade and to eliminate their imbalances on the basis of a continuous trade (Turkish Natural Gas Market Report 2018, EPDK). Table 5.254 summarizes the first four months' market activities in the OTSP.

Table 5.254 **Organized Wholesale Natural Gas Market**

	Number of offers	Number of matches	Volume of matches (bcm)	Transaction value (mill TL)
Sept-Dec 2018	3,626	2,450	0.587	890.1

Source: Turkish Natural Gas Market Report 2018, EPDK

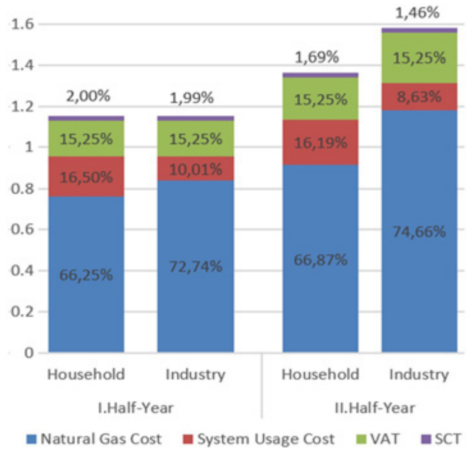
On 5 February 2020, EPIAŞ organized a workshop with the stakeholders to discuss the details like offer type of matching rules, contracts and collaterals of the Natural Gas Futures Market (VGP) to be launched in 2021 (www.epias.com.tr).

Natural gas transmission by pipelines is executed by BOTAŞ. Third party access to transmission network is regulated. The shippers apply to BOTAŞ within the Framework of BOTAŞ Transmission Network Operation Principles. In 2018, 50.97 bcm natural gas was delivered into the transmission pipeline network at 13 entry points and 50.74 bcm was withdrawn from it. In 2018, natural gas was physically transported by 12 entering shippers and 22 exiting shippers in national natural gas transmission network. In addition, there were 30 entering shippers and 27 existing shippers at virtual trade points (Turkish Natural Gas Market Report 2018, EPDK). In 2018, 0.8 bcm was transmitted by 9 licenced LNG transmission companies using LNG vehicles.

In 2018, Natural gas distribution was conducted by 72 distribution companies in 510 cities in 81 provinces. The distribution network reached a total length of 12.875 km steel pipelines, 88,602 km polyethylene pipelines and 36,058 km service lines. 66 million Turkish citizens have access to natural gas and 50.6 million were active consumers.

The total number of customers increased in 2018 to 15.400.892 and the number of eligible consumers to 604.664 (2018 Natural Gas Distribution Sector Report, GAZBIR 2019). The threshold to become an eligible consumer is 75,000 cubic meters. Average Unit Prices of Natural Gas Sold by Distribution and Supplier Companies to Household and Industrial Consumers was in the first half of 2018 around 1.15 TL/cubic meter and increased in the second half of the year to 1.36 TL/cubic meter for households and 1.78 TL/cubic meter for industry. Final sales price includes System usage cost, Value Added Tax (VAT) and Special Consumption Tax (SCT) (Figure 5.308).

Figure 5.308 **Breakdown of Natural Gas Price for Household and Industrial Consumers by Distribution and Supply Companies in 2018.**



Source: Turkish Natural Gas Market Report 2018, EPDK

(g) National NG policy - strategic plan

The basic aspects highlighted in the Strategic Plan 2015-2019 and the 11th Development Plan 2019-2023 are shown below:

- The share of natural gas in electricity generation to be reduced to 20.7% in 2023.
- In order to promote competition cost-based pricing will be adopted.
- In order to increase access to natural gas where appropriate, the transmission and distribution network will be increased.
- Natural gas supply security will be enhanced.
- Underground storage capacity will be expanded to 10 bcm by 2023.

- In order to increase source, country and route diversification FSRU procurement and FSRU network connections will be completed.
- To deepen the trade in Organized Wholesale Market and to start a Futures Market, Derivatives Markets will be established.

(h) Planned new projects

At the time being there is no appetite in the industry to invest further in new natural gas fired power plants.

Transmission and distribution network investments will continue in order to increase access to natural gas. BOTAŞ is investing 2.6 bill TL in new transmission lines until 2023 and 1.5 bill for rehabilitation of existing lines and infrastructure until 2024 (2020 Investment Program). The distribution companies spent 1.7 bill TL for network investments in 2018 and plan to spend a further 1.1 bill TL in 2019 (2018 Natural Gas Distribution Sector Report, GAZBIR 2019). In the coming years, we may expect yearly distribution investments around 1 bill TL. The largest investments will be realized by BOTAŞ in underground storage. Silivri Underground Storage Phase III project, tendered in December 2019, will be finalized in 2022. Total investment of the project is estimated at around 3,5 bill TL. Tuz Gölü Underground Storage Phase II investment project was also tendered in 2019 and has an investment volume of 19.3 bill TL (2020 Investment Program). The project is expected to be commissioned in 2024.

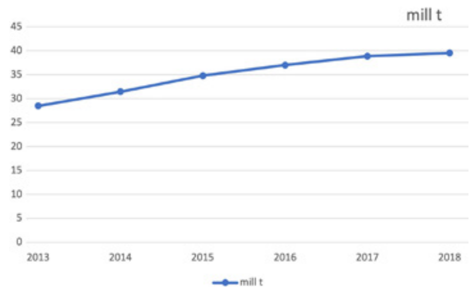
BOTAŞ is investing 450 mill TL for Saros FSRU jetty and network connection until 2021 and will realize remaining investments of 45 mill TL at Dörtyol FSRU until 2021. BOTAŞ is also investing 1.4 bill TL for the procurement of a new FSRU (2020 Investment Program).

Solid Fuels

(a) Supply and consumption

The share of coal in Turkey's primary energy mix in 2018 was 28.4%. In 2018 coal fired power plants generated 113.3 TWh and had a share of 37.3% in the total electricity generation of Turkey. Hard coal, i.e. thermal coal, supply increased from 37.023 Million t in 2016 to 38.879 in 2017 and reached 39.545 Million t in 2018. Turkish hard coal imports in 2018 reached 38.329 million tonnes. Domestic hard coal production in 2018 was about 1.1 million tonnes. Figure 5.309 shows Turkey's hard coal supply since 2013.

Figure 5.309 **Hard Coal Supply in Turkey (2013-2018)**



Source: TTK Turkish Hard Coal Enterprises (2019)

We should note that 60% of the hard coal is used for electricity generation, 15% is used in coke ovens, 14% in industry and the remaining is used for space heating and in other sectors (Table 5.255).

Table 5.255 **Total hard coal supply and sectoral consumption in Turkey (1, 000t)**

* includes heat

** includes ceramic

*** includes nonferrous

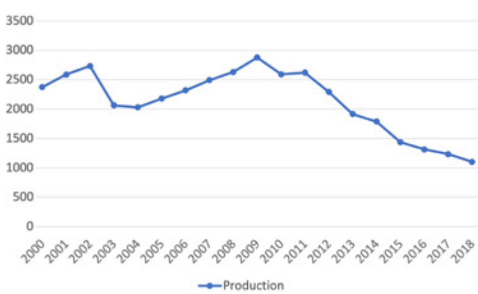
**** includes households, commerce and services.

At the same time, Turkey is a significant lignite producer in its own right. In 2018 lignite demand reached about 81 million tonnes. Nearly 90% of the produced lignite is used on site for power generation, while the remaining is used by industry, for space heating and other users.

(b) Local production and exploration

Despite some 250-300 Million USD yearly subsidies, the hard coal production in Turkey, reached a peak of 4 Million t in early 1980's and since then has been in decline. In 2016 Turkey produced 1.3 Mt, in 2017 1.2 Mt and in 2018 1.1 Mt of hard coal. Fig 5.297 shows Turkey's hard coal production since 2000.

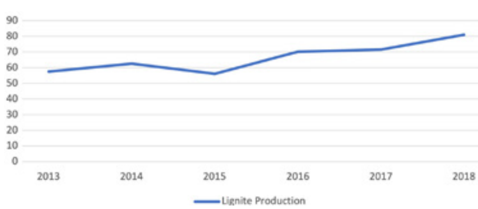
Figure 5.310 **Indigenous hard coal production (1000 t)**



Source: TTK Turkish Hard Coal Enterprises, 2019

Lignite is an indigenous source for electricity generation and plays an important role in Turkey. After Germany, Turkey is the second largest lignite producer in Europe. The lignite production increased from 71.5 million t in 2017 to 81 million t in 2018. (See Fig 5.310)

Figure 5.311 **Lignite production in Turkey (million t)**



Source: TKI Turkish Coal Enterprises, Ministry of Energy and Natural Resources (2019)

Coal exploration activities in Turkey are focused on lignite deposits mainly in central and western Turkey. Intense exploration activities of state agencies between 2005-2015 resulted in an increase of known lignite reserves from 8.3 to 17.9 billion tonnes (Ministry of Energy and Natural Resources, 2019).

(c) Deposits

Turkey's hard coal deposits were discovered in the first half of the 19th century and stretch along the western Black Sea coast from Ereğli in the west over Zonguldak to Amasra. Based on the drilling results up to a depth of -1200 m the total reserves are estimated at 1.5 billion tonnes and the proven reserves 735.9 million tonnes (TTK Turkish Had Coal Enterprises, 2019). The calorific value of the coal varies between 6,200 and 7,250 kcal/kg. The steep bedding of the coal seams and the complex geology of the basin does not allow the mechanized exploitation of coal.

Map 5.78 **Coal deposits in Turkey**

Source: Revised from MTA General Directorate of Mineral Research and Exploration Institute, 2019

The majority of lignite deposits in Turkey are to be found in Western, Central and Eastern regions of the country and also in the Thrace region West of Istanbul (see Fig 26). The lignite reserves are estimated at 17.9 billion tonnes (Ministry of Energy and Natural Resources, 2019). The calorific value of Turkish lignite varies between 1,000 kcal/kg and 5,000 kcal/k. The majority of the reserves (68%) are below 2,000 kcal/kg, 23,5% between 2,000-3000 kcal/kg and the remaining 8.5% between 3,000-5,000 kcal/kg (TKI Turkish Coal Enterprises, 2018).

(d) Core imports

Turkey is one of the largest importers of hard coal in Europe together with Germany and Holland. Turkish hard coal imports increased from 12.9 million tonnes in 2000 to 38.3 million tonnes in 2018 (ETKB, 2019). In 2017 Colombia was the largest hard coal supplier of Turkey with 17.3 million tonnes followed by Russian Federation with 14.4 million tonnes, South Africa 2.2 million tonnes, USA 1.8 million tonnes and Australia 1.1 million tonnes (IEA Coal Information, 2018).

(e) Planned new projects

During the last five years planned coal fired power generation projects have been substantially reduced. Many of them are on hold because of NGO resistance, slowing electricity demand and unfavourable financing conditions, while others because of technical problems related to lignite deposits and specifications.

The only sizeable indigenous hard coal project of Turkey is the Amasra Hard Coal Project of Hattat, holding some 5 million t/a of reserves. With the planned investment of 3.5 billion USD, Amasra is the largest new hard coal project in Europe (Hattat). The project site is on the eastern end of the basin. Since 2005 the company conducted 260 deep development drillings to assist the mine design. Three shafts with 8 m diameter and 570 m, 700 m and 730 m depth were sinked and 25 km of galleries were driven. The project has been delayed considerably because of NGO resistance and court decisions against the planned 2x550 MW power plant to be fed from the mine.

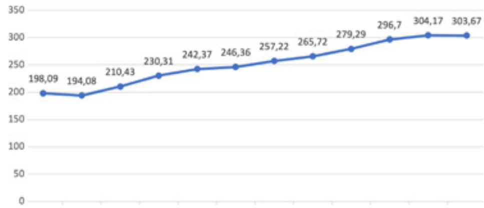
Huge lignite projects like the Afşin-Elbistan (7,000 MW), Konya-Karapınar (5,000 MW) or Afyon-Dinar (3,500 MW) have been postponed. As of January 2020, from 8,200 MW coal fired power plants in the construction phase about 4,960 MW have a realization rate of more than 10% (Energy Market Regulatory Authority, January 2020). We may expect that some of them will be further delayed, and only 3 projects with a total capacity of 1474 MW may be commissioned until 2024. According to Platts, "An estimated 70 GW of planned capacity has either been cancelled or indefinitely postponed since 2009. An additional 33 GW is under various stages of planning, with only 2 GW under construction," (IEEFA, August 26, 2019). Despite these negative developments, one may expect an acceleration of power plant projects with a sustainable economic growth in the coming years.

Electricity

(a) Electricity supply and demand

In 2018, Turkey's gross electricity consumption was 304.2 TWh. This means an increase of 2.5% compared to 296.7 TWh in 2017. Figure 5.312 shows the development of gross electricity consumption since 2008. According to the preliminary figures the gross electricity demand reduced in 2019 to 303.7 TWh due to the slowdown of Turkish economy.

Figure 5.312 **Gross electricity consumption 2008-2019 (TWh)**



Source: TEİAŞ, April 2020, (*) 2019 figure provisional

Ministry of Energy and Natural Resources (ETKB) prepared an Electricity Demand projection for the 2019-2039 period (Table 5.256). The ETKB study was based on three scenarios with yearly average demand growth of 2.90% (low demand, scenario 1), 3.36% (reference demand, scenario 2) and 3.84% (high demand, scenario 3).

Table 5.256 **Electricity demand projection 2019-2039**

Years	Scenario 1		Scenario 2		Scenario 3	
	TWh	Change	TWh	Change	TWh	Change
2019	313.8	-	315.2	-	316.5	-
2020	327.3	4.3%	329.6	4.6%	332.1	4.9%
2021	340.5	4.0%	344.4	4.5%	348.7	5.0%

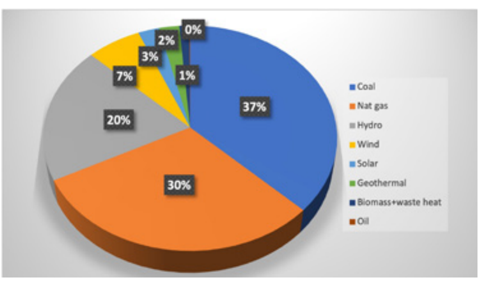
2039	556.3	2.1%	613.4	2.3%	679.9	2.6%

Source: Ministry of Energy and Natural Resources.

In 2018 electricity generation increased to 304.8 TWh, up by 2.9% compared to 297.3 TWh in 2017. Coal was the leading fuel with 37.15% participation in the electricity mix, followed by natural gas with 30.34% and hydro with 19.66%. Wind (6.54%), solar (2.56%) and geothermal (2.44%) contributed together with 11.5%. Biomass, biogas and waste heat counted for 1.2% of electricity generation. Figure 5.313 shows the breakdown of electricity generation by fuel type. Hydroelectricity production in 2018 was relatively low compared to long-term average.

According to preliminary figures announced in January 2020 by TEİAŞ, in 2019 the share of hydropower increased to 29%. While the share of coal was stable, the share of natural gas reduced to 19%. The share of remaining renewables including biomass and waste heat increased by 2%. If those figures are verified, Turkey in 2019 realized a historically high generation from hydro and renewables reaching a share of 44% and exceeding by far the target to supply at least 30% of its total electricity from renewable sources by 2023. This is partly due to the highwater income of hydropower plants after the dry year 2018.

Figure 5.313 **Electricity generation by fuel types 2018**



Source: TEİAŞ

Table 5.257 shows the development of total electricity generation, electricity imports and exports and gross demand.

Table 5.257 **Development of electricity generation, import, export and gross demand in Turkey (2008-2019) (TWh)**

	Total generation	Import	Export	Gross demand
2008	198.418	0.789	1.122	198.085

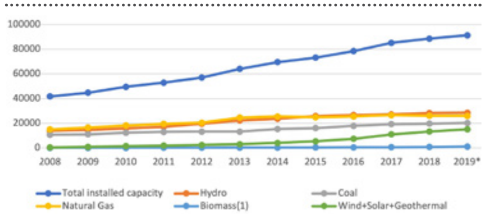
Development of electricity generation, import, export and gross demand in Turkey (2008-2019) (TWh)

(b) Installed Capacity

In 2018 the installed electricity capacity of Turkey increased by 3.9% and reached a total of 88,550.8 MW (2017: 85,200.0 MW). According to preliminary data, the installed capacity reached in 2019 was 91,267 MW (TEİAŞ, Jan 2020). Figure 5.314 shows the development of generation capacity since 2008.

Figure 5.314 **Installed electricity capacity in Turkey, 2008-2019 (MW)**



Source: Turkish Electricity Transmission Company TEİAŞ, Jan 2020. (*) 2019 preliminary data, (1) includes waste und waste heat.

The installed capacity of *hard coal fired power plants* (including asphaltite) in Turkey increased from 1,986 MW in 2008 to 9,576.4 MW in 2018 and according to preliminary figures to 10,182.7 MW in 2019. Some 8,966.9 MW of this capacity belong to 15 plants commissioned since 2003 and use imported hard coal. Four (4) plants with a total of 810.8 MW capacity are using domestic hard coal and one plant with 405 MW capacity in south-eastern Turkey uses locally produced asphaltite.

Despite grandiose development plans by the government, the *lignite fired* power plant capacity increased modestly from 8205 MW in 2008 to 9456.1 MW in 2018. According to preliminary data, the installed lignite capacity reached 10,101 MW in 2019 (TEİAŞ, Jan 2020).

After an investment boom of about 15 years, the installed capacity of *natural gas fired power plants* has stagnated since 2014. The installed capacity increased from 15,054.8 MW in 2008 to 25,508.1 MW in 2014. In 2018 the capacity was 26.070 MW and in 2019 25.902.3 MW. Increasing generation from renewable resources is certainly one reason, but more important are the economic conditions, like low electricity prices. Some generators have shut down due to adverse conditions, others are kept in stand-by condition under the capacity payments scheme.

Installed capacity of *hydroelectric powerplants* increased from 13,827.7 MW in 2008 to 28,291.4 MW in 2018 and to 28,503 MW in 2019 according to preliminary data (TEİAŞ, Jan 2020). Total installed hydroelectric capacity in Turkey in 2019 was 7860.5 MW, using 558 run of-the river-type generators and the remaining 20.642.5 MW using 124 generators with reservoir.

Akkuyu, the only *nuclear power plant* under construction has been delayed.

Installed capacity of *wind, solar and geothermal* increased from 393.5 MW in 2008 to 13,350.7 MW in 2018 i.e. 33 times. Despite economic slowdown the capacity increased by 13% in 2019 to 15,101.1 MW. The installed capacity of biomass plants increased from 60 MW in 2008 to 738.8 MW in 2018 and according to preliminary data to 801.6 MW in 2019.

c) Planned new capacity – investments

There are 21 licenced natural gas fired power plant projects and cogeneration facilities with 3,535 MW capacity in construction phase. Eleven (11) such projects with an installed capacity of 341 MW, the majority being cogeneration facilities, have a realization rate of over 50% and may be commissioned in 2020 and 2021. Some of the larger generation projects may be further delayed.

Similarly, large lignite power plant projects are either postponed or cancelled. Largest ever planned local hard coal project (2x550 MW) of Turkey near Amasra in the Black Sea coast is still trying to survive. The environmental impact study of the project was cancelled in February 2019 by the High Administrative Court DANIŞTAY according to an appeal by NGO groups. The new integrated study analysing the environmental impact of the power plant together with the coal mine and auxiliary facilities like cinder dump and harbour has been prepared and submitted to the authorities (Enerji Günlüğü). Total investment of the project may reach 3.5 billion US$. The project may be commissioned earliest in 2027.

Other large projects such as the 2x660 MW Emba Hunutlu power plant with a total investment cost of 1.7 bill. US$ is under construction in the Mediterranean coast in Adana province, and will burn imported hard coal (EMBA). The consortium under the lead of Shanghai Electricity Corporation intends to commission the plant in 2023. According to EPDK, there are 12 projects with 8,200 MW licenced capacity in construction phase (Electricity Investment Realization January 2020, Energy Market Regulatory Authority EPDK). Three projects with 1,474 MW capacity may be commissioned until 2024 and the remaining until 2030 or later.

According to State Hydraulic Works DSI, there are 3,636 MW of hydropower capacity in construction phase and 15,995 MW in the planning phase (Table 5.258).

Table 5.258 **Utilization of hydroelectric potential in Turkey**

Status	**Number**	**Installed demand**	**Average generation**	**Share (%)**
Operational	683	28,571	99,628	62.0
Under Construction	47	3,636	11,962	7.5
Planning stage	526	15,995	48,745	30.5
Total	1,256	48,202	160,335	100.0

Source: DSI 2019 Activity Report, 2020.

5

Three large and difficult hydropower projects with a total installed capacity of 2,275 MW are making good progress. The 558 MW Yusufeli Dam on Çoruh river near the Georgian border and Turkey's fourth largest hydropower plant, the 1,200 MW Ilısu Dam on Tigris in Southeast Turkey are being constructed by the public authority State Hydraulic Works DSI. The third project the 517 MW Çetin Dam on Botan river in Southeast Turkey belongs to Limak Holding. All three projects may be commissioned until 2023. From the remaining hydropower projects in different phases of planning 2,000 MW may be realized until 2030 according to the economic growth of the country in the coming years. The 208 MW Zap Hydropower plant in Southeast Turkey with a remaining investment of 0.5 bill TL is planned to be commissioned until 2026. DSI will start with the construction of the 160 MW Silvan Hydropower plant in Southeast Turkey in 2020 and will spent some 0.8 bill TL until 2026.

The Akkuyu Nuclear Power Plant (NPP), the first commercial nuclear power plant to be built in Turkey is currently being implemented in accordance with the Intergovernmental Agreement concluded between the government of the Russian Federation and government of the Republic of Turkey on May 12, 2010. The ground-breaking ceremony of the project took place on April 3, 2018. Akkuyu NPP project with an installed capacity of 4800 MW has four 3+ generation VVER-1200 units. Akkuyu NPP is an AES-2006 serial project based on the Novovoronezh-2 type power plant in Russia (Akkuyu Nükleer A.Ş.). The project has an estimated CAPEX of 20 billion USD and an operating period of 60 years. The project will be developed, financed, operated and decommissioned by Akkuyu Nükleer A.Ş. owned by Rosatom. The Turkish side guarantees the purchase of 50% of the generated electricity within the first 15 years at a price of 12.35 UScents/KWh. Akkuyu nuclear power plant's first unit is expected to generate electricity in late 2023 or in 2024. Construction of the other three units will be completed by 2028.

According to the Turkish Wind Energy Association TÜREB, 25 projects with a capacity of 1,309.8 MW are under erection followed by 35 licenced projects with 1233.6 MW capacity yet to begin, whereas 102 projects with 4,812.6 MW capacity have pre-licence (TÜREB Wind Energy Statistic Report, January 2020). An additional 1,000 MW is assigned to the successful bidders of the second "Regulation on Renewable Energy Resource Areas" YEKA auction. The decision makers acknowledge that the target for 20,000 MW wind capacity in 2023 is not realistic. Some 4,000-5,000 MW of new wind capacity may be installed until 2023, depending on the new feed in tariff applicable from 2021. With a good economic growth and functioning new feed in tariffs Turkey may well achieve the 2023 target of 20,000 MW wind capacity by 2030.

The solar PV investment boom may continue during the 2020-2030 period. We may expect the realization of the 1000 MW first YEKA auction investments until 2023 and planned second 1000 MW YEKA auction investments until 2025. But unlicensed distributed generation on rooftops and facades will continue to be the driving force behind the growth. With new YEKA auctions and/or favourable feed-in tariffs the installed solar PV capacity by 2030 may reach 17,000 MW.

Geothermal electricity generation investments during the past years exceeded government targets. If the present favourable conditions continue, we may expect new investments of about 1,500 MW and an installed capacity which may reach 3,500 MW by 2030.

According to EPDK, there are 48 biomass projects with an installed capacity of 357 MW in the construction phase (Electricity Investment Realization January 2020, Energy Market Regulatory Authority EPDK). We may expect about 700 MW new capacity during 2020-2030 with a total installed capacity of biomass plants reaching 1,500 MW by 2030.

(d) Electricity imports – exports and (f) Cross-border interconnections

Turkey's electricity imports reached its peak in 2014 with 8 TWh, increasing from 0.8 TWh in 2008. Since then, electricity imports have decreased to a level of 2.5 TWh in 2018. According to provisional data from TEİAŞ, the imports reduced further in 2019 to 2.2 TWh. In 2018, 83.3% of the electricity imports were realized from Bulgaria and the remaining from Georgia (16.3%) and Greece (0.4%). In 2018 electricity exports from Turkey were 3.1 TWh and reduced in 2019 to 2.8 TWh (TEİAŞ). About 95% of electricity exports in 2018 went to Greece and the remaining 5% to Bulgaria and Georgia (Electricity Market Development Report 2018, EPDK May 2019).

The Turkish electricity grid is interconnected in the south via a 400 kV line of 400 MW capacity with Syria. In the East there are interconnections with Iraq, Iran, Azerbaijan, Armenia and Georgia. In the West, the Turkish grid is interconnected with the ENTSO-E network via a 400 kV line to Greece and two 400 kV lines to Bulgaria.

Following a trial period since 2010, the permanent parallel operation of Turkey's grid with the ENTSO-E network started in late 2014. In 2015 the export and import capacity to and from ENTSO-E grid has been fixed as 500 MW and 650 MW respectively. Turkish TSO TEİAŞ is co-founder and shareholder of the Coordinated Auction Office in South East Europe SEE CAO. Since October 2015, the cross-border transmission capacity between Greece and Turkey is allocated by SEE CAO on daily, monthly and yearly basis (TEİAŞ).

Electricity Market and Competition

With a 14.80% EÜAŞ had the largest share in electricity generation in 2018, followed by Eren Enerji of the Eren Holding with 5.80% and EnerjiSA, a joint-venture of E-on and Sabancı Holding with 3.93% (Electricity Market Development Report 2018, EPDK May 2019).
An important milestone for the creation of wholesale market mechanisms in the Turkish power sector was the establishment of Day-Ahead Market on 1 December 2011.
Energy Exchange Istanbul EPİAŞ was established in March 2015 and now operates the Day-Ahead Market, the Intra-Day Market and the Balancing Power Market. According to EPİAŞ, the physically settled Power Futures Market is operational since 1 December 2020. In 2018, the Weighted Average Market Clearing Price in Day-Ahead Market increased by 38,65% to 233,101 TL/MWh and the Average System Marginal Price increased by 42,27% to 234,436 TL/MWh compared to 2017 (Electricity Market Development Report 2018, EPDK May 2019). The annual weighted average of the price in the Balancing Power Market was 234,436 TL/MWh in 2018, increased by 42,27% compared to the previous year.

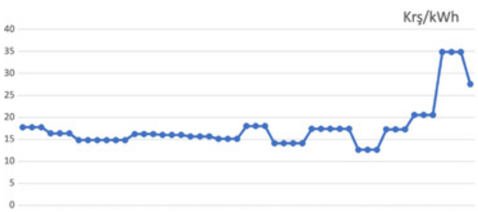
In 2018, the eligible consumer limit was set at 2.000 kWh and accordingly the theoretical market openness rate for demand side was calculated as 92,6%, but actual market openness was 29,6%.

According to analyses based on the Herfindahl-Hirschman Index (HHI) both the electricity generation (1,028) and installed capacity (1,184) lost their oligopoly market character over the years and in 2018 were at a medium intensity level (1,000-1,800). HHI value for the sales of supplier license holders to end-users (494) was at competitive level (Electricity Market Development Report 2018, EPDK May 2019).

(e) Tariffs

Wholesale active electricity tariff of Public generation company EÜAŞ, mainly for sales to distribution companies are quarterly approved by the Energy Market Regulatory Authority EPDK as shown in Fig. 30. Market participants are criticizing this system and argue that the wholesale price of EÜAŞ is not cost-based and distorts competition.

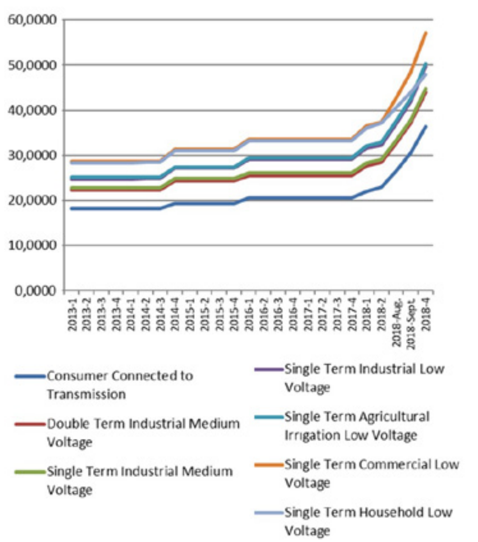
Figure 5.315 **Development of active electricity wholesale price of EÜAŞ (formerly TETAŞ)**



Source: Energy Market Regulatory Authority EPDK, 2020, (100 Krş = 1 Turkish Lira)

Retail Sales Tariff to non-eligible consumers is also approved quarterly by the EPDK and visible at its website. The tariff structure is complicated and contains over one hundred sub-tariffs like low-medium voltage, single-double term, day-night-peak-single time, for industrial, commercial, residential consumers and for agricultural irrigation and lighting. In 2018, the share of energy cost in the final invoice for residential consumer was 54%, followed by 26% network cost, 15% VAT and 5% other taxes, fees and funds.

Figure 5.316 **Development of electricity tariffs before taxes and funds 2013-2018 (Krş/kWh)**



Source: Electricity Market Development Report 2018, EPDK 2019

The Last Resort Tariff is applied to eligible consumers. The tariff aims to encourage eligible consumer with high consumption to purchase their electricity via bilateral contracts from retail companies by applying them higher electricity tariffs.

Transmission System Usage and Transmission System Operating Tariffs for generators and consumers in the 14 regions are prepared by TEİAŞ and approved by EPDK. Final payment of the user to TEİAŞ includes an additional Transmission Surcharge as 0.5% of the applied transmission tariff. Following the preparation of the legal framework in 2016, Turkey in January 2018 introduced an *Electricity Market Capacity Mechanism*. TEİAŞ is making capacity payments to applying, eligible generators based on their fixed cost in order to guarantee security of supply in the electricity market.

(g) Planned new projects

The 2019-2023 development plan includes items regarding the development of the electricity transmission network. Those include the following:

- technical projects to ease the integration of new renewable generation capacities,
- strengthened and more flexible networks,
- increased system reliability,
- increased cross-border interconnection capacities in order to allow more trade,
- realization of Van Back to Back DC interconnection project with Iran,
- realization of a new DC line along the Tortum-Georgia border.

The size of the Turkish transmission network increased to 68,203.8 km in 2018 (40,564.7 km in 1999). Considering the network growth over the last 20 years and increased demand with the integration of new renewable capacities, we may expect that the length of transmission network may reach 90,000 km by 2030.

The number and capacity of substations reached 1826 and 172,276.1 MVA in 2018 (965 and 52,022.6 MVA in 1999). The substation capacity may reach 250,000 MVA in 2030.

Transmission system operator TEİAŞ plans to invest 17.3 bill TL until 2023 mainly in new network and substations.

Operators of the privatized regional electricity distribution companies committed themselves to invest a total of 28.5 billion TL between 2016-2020 to improve the distribution network and to reduce losses. According to the Association of Distribution Services ELDER during 2016-2019 period, the planned investments were widely realized and reached about 26.9 billion TL (Bloomberg 12 Jan, 2020). We may expect that the investments into the distribution networks may continue after 2020. The focus of the investments will be reduction of distribution losses, introduction of smart grids, remote metering and smart electricity meters.

The development plan expects the installed capacity to reach 109,474 MW at the end of 2023. According to this forecast 18,207 MW of new capacity will be added to the system until 2023 during the last four years of the development plan. The development plan and the 2020 Investment programme foresees rehabilitation investments for power plants belonging to EÜAŞ until 2026. Those are the lignite fired 1,440 MW Afşin-Elbistan B power plant (50 mill TL), the 1,800 MW Karakaya hydropower plant (175 mill TL), the 1,330 MW Keban hydropower plant (0.5 bill TL) and the 128 MW Hirfanlı hydropower plants (180 mill TL).

The development plan expects the continuation of efforts for the construction of two more nuclear power plants, additional to the one at Akkuyu.

In February 2020, the Turkish government published a regulation for the grid connection of energy storage systems (Official Gazette, 19.2.2020). With economic incentives yet to be published, the new legislation will primarily support storage projects related to solar PV facilities but also Pumped Storage Hydroelectric plants. EÜAŞ plans to realize the first Pumped Storage Hydroelectricity project in Turkey until 2032. In a preliminary study between 2007-2009 18 potential sites were identified and analysed. In 2010-2011, EÜAŞ and Tokyo Electric Power Corporation conducted the "Study on Optimal Power Generation for Peak Demand in Turkey" and reduced the number of projects using a step-by-step analysis to find the optimum sites. Conceptual design of the best two projects, the Gökçekaya Pumped Storage Hydropower plant (1,400 MW) in Eskişehir province, in Central Turkey and the Altınkaya Pumped Storage Hydropower plant in Samsun province, in the Black Sea Region were realized (YEGM). The projects will use the reservoirs of the existing hydropower plants with the same name as the lower reservoir for the pumped storage facilities. EÜAŞ will start the Gökçekaya project with a budget of 6.3 bill TL in 2020 (2020 Investment Program, YEGM).

It should further be noted that in 2020, DSI will start construction of the 160 MW Silvan Hydropower project in Southeast Turkey and plans to invest 0.8 bill TL until 2026.

Renewables

(a) Overview of the sector's development

According to the National Renewable Energy Action Plan and in compliance with the EU Directive 2009/28/EC, Turkey targets to supply at least 30% of total electricity from renewable sources by 2023. However, this target has already been achieved. The 11th Development Plan sets a target of 38.8% for the share of electricity from renewables by 2023. Since 2010 the country is experiencing a boom in renewables investments starting with hydropower and wind farms. The highest new hydropower capacity with 2,225 MW was connected to the electricity network in 2015 and new wind power capacity with 1,386 MW in 2016. Geothermal power investments surpassed even the expectations of the energy planners. The original target of 600 MW total installed capacity by 2023 was exceeded in 2015. Solar PV installations started to boom since 2015. A record year for solar PV investments was 2017 with 2,588 MW of new installed capacity. Since then, we see a slowdown of renewables investments. There are several reasons for the reduced pace of renewables investments seen currently. NGO resistance against new hydropower development especially in the Black Sea region were followed by protests against new wind farms in the Westcoast. New in the scene are the NGO campaigns against geothermal powerplants in Western Turkey. Regulatory reasons like difficulties to obtain new licences is an important factor. Last but not least, economic factors like weak demand and reduced appetite by the commercial banks for new loans for energy investments also play a role.

(b) Legislation, incentives and national RES policy

Law No. 5346 on "Utilization of Renewable Energy Sources for the Purposes of Generating Electrical Energy" from 2005 and its amendment with Law No. 6094 from 2011 were the main legislation supporting mechanisms for renewables energy investments in Turkey. The renewable energy Law introduced a feed-in tariff system (YEKDEM) to support renewable electricity generation of licenced and non-licenced investments. Depending on the type of renewable energy projects the incentive differs between the Turkish Lira equivalent of 7.3 and 13.3 US cents/kWh (see Table 5.259). These tariffs are applicable for projects starting electricity generation before 31st of December 2020 for a period of ten years.

Table 5.259 **YEKDEM tariffs (US cents/kWh)**

Hydropower	7.3
Wind	7.3
Geothermal	10.5
Biomass	13.3
Solar (PV;CSP)	13.3

According to the Renewables Law an additional mechanism is the locally manufactured equipment support. Regulation on "Local Components in Facilities Generating Electricity from Renewable Energy Resources" from 2016 determines the additional incentives according to the percentage of domestically manufactured components in the relevant equipment. Local components support is applicable for licenced projects starting electricity generation before 31st of December 2020 but only for a period of five years. The premium to be paid for the use of a locally manufactured component varies between 0.4- 2.4 US cents/kWh. The maximum additional incentives are shown in Table 5.260.

Table 5.260 **YEKDEM maximum locally manufactured component support tariff (US$cents/kWh)**

Hydropower	2.3
Wind	3.7
Geothermal	2.7
Biomass	5.6
Solar PV	6.7
Solar CSP	9.2

The new incentive scheme to succeed the expiring YEKDEM system is under preparation. The government is meeting with stakeholders from industry and finance to obtain their views in order to formulate a new feed-in tariff system. Because of the hardship created by the Covid-19 pandemic, the lobby organizations of renewable investors were advocating six months to one-year extension of the existing YEKDEM system. In September 2020, the government extended the deadline to June 30, 2021 (Official Gazette, 18.9.2020).

In October 2016 the government introduced the "Regulation on Renewable Energy Resource Areas" (YEKA) auction model. Different from the YEKDEM, the YEKA model requires the successful bidders of the auctions to use locally manufactured equipment. The bidder offering the lowest electricity purchase price is the winner of the auction. Electricity purchase is guaranteed for 15 years after the signing of the contract. There are different types of YEKA auctions. One YEKA model applied in the first round of auctions allocated 1,000 MW installed capacity to one generator with the condition of investment in equipment production and research & development.

A second round of auction allocated to four successful bidders each with 250 MW installed capacity. A new type of "Renewable Energy Resource Areas" auction with smaller installed capacities called "mini YEKA" is under preparation.

The envisaged auction dates of October 19-23, 2020 have been postponed to January 18-22, 2021 (AA, 8.10.2020). This first mini YEKA auction will take place for 74 locations with solar installed capacities of 10, 15 and 20 MW.

Unlicensed renewable energy generation model contributed heavily to the boom of solar PV investments in Turkey. The legal base of the model was the "Regulation on Unlicensed Generation in Electricity Market" No. 28783 from October 2013 amended with the Regulation No. 30772 from May 2019. Investors with projects up to 5 MW capacity (previous Regulation 1 MW) do not require a production licence or to have established a company.

On February 19, 2020 the Turkish government published a regulation for the grid connection of energy storage systems. With economic incentives yet to be published, the new legislation will primarily support storage projects related to solar PV facilities but also to Pumped Storage Hydroelectric plants. On 8 March 2020, the Energy Market Regulatory Authority issued a regulation amendment dealing with hybrid electricity generation.

The new legislation determines the rules for electricity generation from multiple sources with single licence at one connection point to the network. As of August 1, 2020 a green electricity tariff has been introduced.

(c) Installed capacity per source

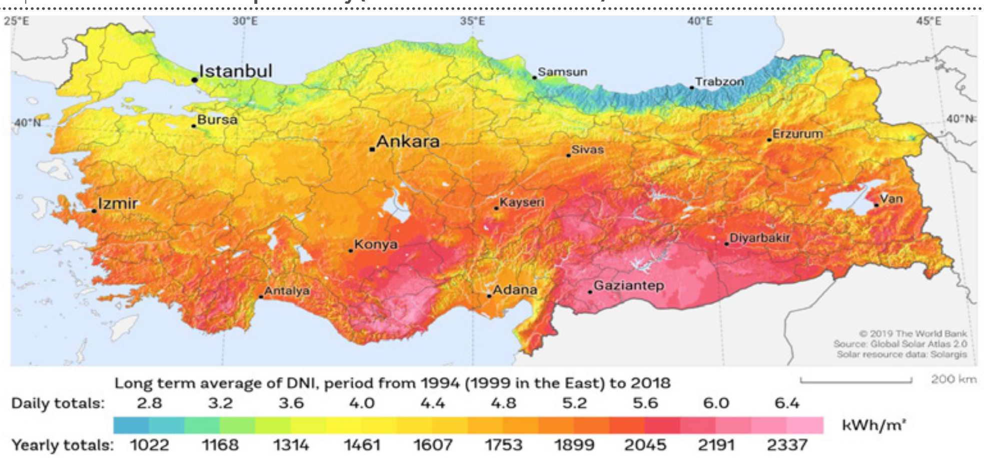
Solar (Thermal, PV)

The total annual insolation time of Turkey is 2,741 hours, and the total incident solar radiation is 1,527 kWh/m2 per year.

Since 1970's solar thermal applications especially solar water heaters are widely used in Western and Southern regions of Turkey. In 2017 Turkey had after China and US the 3rd largest installed solar thermal capacity in the world with 16,287 MWth (Weiss, Spörk-Dür: Solar Heat Worldwide, 2019 Edition). Turkey's solar thermal use increased from 0.843 Mtoe in 2017 to 0.877 Mtoe in 2018 (ETKB, 2019).

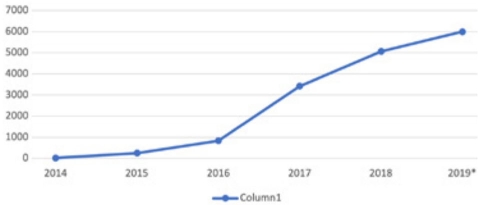
The 2023 goals released in 2010 did not mention a concrete figure for solar at electricity investments but in 2014 with the Renewable Energy Action Plan the target was fixed at 5,000 MW. The Strategic Plan for 2015-2019 set a target of 3,000 MW for 2019. Regarding solar PV installations in 2017, Turkey had the highest growth rate in Europe. The installed capacity increased from 832.5 MW in 2016 to 3,420.7 MW in 2017, a growth rate of 310%. At the end of 2018, the installed solar electricity capacity reached 5,062.7 MW, i.e. a growth of 48% in comparison to 2015 (see Fig. 5.318). According to preliminary figures the growth slowed down in 2019 and the installed capacity reached about 6,000 MW. The bulk of this capacity is stemming from unlicensed, distributed generation facilities, mainly on rooftops.

Map 5.79 **Solar resource map of Turkey (Direct Normal Irradiation)**



Source: Global Solar Atlas,2019

Figure 5.317 **Development of installed solar PV capacity in Turkey (MW)**



Source: Turkish Electricity Transmission Company TEİAŞ, (*) 2019 preliminary figure.

The government and the regulator were rather restrictive concerning the size of licensed solar PV investments. The average installed capacity of licensed generators increased from 17.9 MW in 2017 to 81.7 MW in 2018. The preliminary figure for licensed installed solar capacity for 2019 is 169.7 MW (Energy Market Regulatory Board EPDK, 2020).

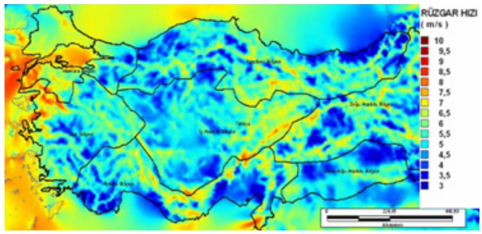
The first YEKA model auction for solar PV was held in March 2017. The consortium led by Kalyon Holding offering 6.99 US$cents/kWh won the bid for 1 GW capacity in Karapinar, Province Konya. In December 2019 Kalyon commenced the manufacturing investment in Ankara as part of the bid. The 400 Million $ facility with an annual capacity of 500 MW PV panels will manufacture solar ingots, wafers, cells and modules (Enerji Portalı, 13.12.2019). After the inauguration of the factory in August 2020, the installation of PV panels started and already in September 4 MW capacity has been commissioned (Milliyet, 28.9.2020).

The second YEKA auction for solar PV to take place in 2019 with a total capacity of 1 GW divided into 500 MW, 300 MW, and 200 MW blocks in three regions has been cancelled. After a legislation amendment, the next round of auctions will be held as mini YEKA on January 18-22, 2021 (AA, 8.10. 2020). The potential investors will bid for capacities between 20 MW in 36 provinces.

Wind

The wind energy potential of Turkey has been estimated as 48,000 MW including 10,000 MW from off-shore areas as shown in Figure 5.318. 61% of this potential has a wind speed of 7-7.5 m/s, 27% 7.5-8.0 m/s and 11% a highest speed at 8-9 m/s (Ministry of Energy and Natural Resources).

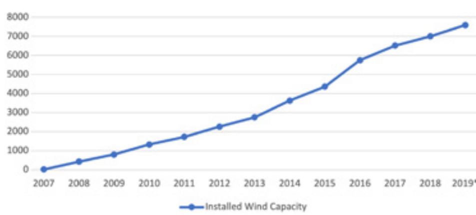
Figure 5.318 **Distribution of annual average wind speed at 50 m height**



Source: Ministry of Energy and Natural Resources.

The 2023 goals released in 2010 were targeting 20,000 MW of installed wind capacity. Later this capacity was also included in the Renewable Energy Action Plan. The Strategic Plan of 2015-2019 set a target of 10,000 MW for 2019. The 2023 target seemed difficult to achieve but even the 2019 target was missed. Installed capacity of wind power plants increased in 2018 to 7,005 MW from 6,516 MW in 2017. According to preliminary figures the installed capacity in 2019 increased to 7,591.2 MW (TEİAŞ, January 2020). Figure 5.319 shows the development of wind power in Turkey between 2007-2019.

Figure 5.319 **Development of installed wind capacity in Turkey (MW)**



Source: Energy Market Regulatory Board EPDK, 2019, TEİAŞ Turkish Electricity Transmission Company, 2020, (*) 2019 preliminary figure.

Until 2014, the majority of wind power generators preferred to sell their electricity to the market. Since then, this trend has been reversed. For 2016, 99% of the eligible wind capacity applied for YEKDEM feed-in tariff system and later all generators followed.

The first YEKA auction in August 2017 for 1.000 MW capacity with manufacturing investment and research & development obligations was won by a consortium led by Siemens-Türkerler-Kalyon with an electricity sales price of 3.48 UScents/kWh. The consortium will build wind farms of minimum 50 MW in five assigned regions: Kayseri-Nigde, Sivas, Edirne-Kirklareli-Tekirdag, Ankara-Çankiri-Kirikkale and Bilecik-Kütahya-Eskisehir. In order to fulfil the local manufacturing requirement, consortium partner Siemens Gamesa finalized a 100 million $ investment in Aliağa near Izmir by the end of 2019. The facility will produce 100 nacelles per year. According to the Izmir Development Agency, with the existing manufacturing facilities of Enercon, General Electric LM wind Power, TPI composites, CS wind and parts suppliers like Ateş Çelik, Dirinler Döküm, Norm Civata and Tibet Makina the Izmir region became a hub of Wind technology (Anatolian Agency AA, 5.11.2019).

The second round of YEKA auction for 4x250 MW capacity was realized in May 2019. The lowest electricity sales price with 3.53 UScents/kWh was offered for 250 MW capacity in Balıkesir province by Enercon. 250 MW capacity in Çanakkale province was won with 3.67 UScents/kWh by Enerjisa. Enercon won the auction for 250 MW capacity in Muğla province with a sales price of 4.00 UScents/kWh. The auction for 250 MW in Aydın province was won by Enerjisa with 4.56 UScents/kWh. The successful bidders are obliged to use equipment with at least 55% local components on average.

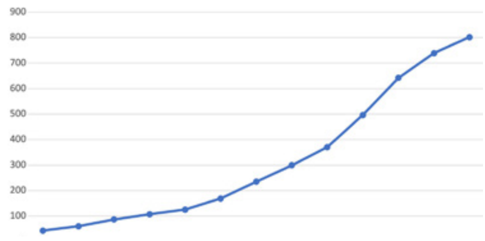
An offshore wind auction announced in 2018 has been cancelled due to feasibility concerns by the stakeholders.

Biomass

According the recently published "Biomass Energy Potential Atlas" Turkey's yearly biomass potential equals to 14.6 Mtoe, including 4.4 Mtoe animal waste, 6.0 Mtoe plant waste, 0.9 Mtoe forestry waste and 3.4 Mtoe municipal waste (Ministry of Energy and Natural Resources, January 2020).

The 2023 goals released in 2010 did not mention a concrete figure for biomass electricity investments but later the National Renewable Energy Action Plan 2013-2023 published in 2014 set a target of 1,000 MW for 2023. The Strategic Plan 2015-2019 set a target of 700 MW for 2019. The installed capacity of generators from biomass exceeded this target and in 2019 reached 801.6 MW (Turkish Electricity Transmission Company, January 2020). After high capacity growths in 2017 (34%) and 2018 (29%), there this is a modest increase of 9% from 738.8 MW in 2018. Figure 5.320 shows the development of biomass electricity generation capacity in the period 2007-2019.

Figure 5.320 **Biomass installed capacity in Turkey (MW)**



Source: Turkish Electricity Transmission Company TEİAŞ, (*) preliminary figure.

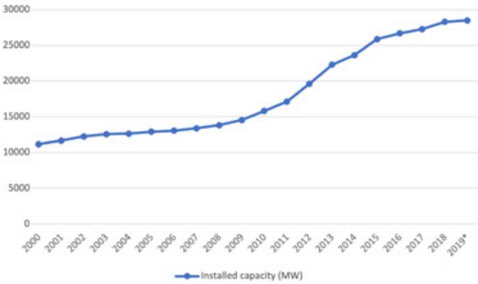
Hydro

State Hydraulic Works DSI estimates Turkey's theoretical hydroelectric potential as 432 TWh/year (www.dsi.gov.tr).Recognising the technical, economic and environmental constrains, an installed capacity of around 40,000 MW may be realized.

Turkish Energy Strategy 2023 targets released in 2010 set the full utilization of hydropower potential as a target. Later, the National Renewable Energy Action Plan mentioned 34,000 MW for 2023. The Strategic Plan for 2015-2019 set a target of 32,000 MW for 2019. Today, the realization is behind those figures. At the end of 2019 Turkey's installed hydroelectric capacity reached 28,503 MW; an increase of less than 1% compared to 28,291.4 MW from 2018 (Turkish Electricity Transmission Company, January 2020).

Figure 5.321 shows the development of the hydroelectric capacity between 2000 and 2019.

Figure 5.321 **Installed capacity of hydroelectric plants in Turkey (MW)**



Source: Turkish Electricity Transmission Company TEİAŞ, (*) preliminary figure.

7860.5 MW of the total hydroelectric capacity in 2019 is installed at 558 run of-the river-type generators and the remaining 20.642.5 MW at 124 generators with reservoir.

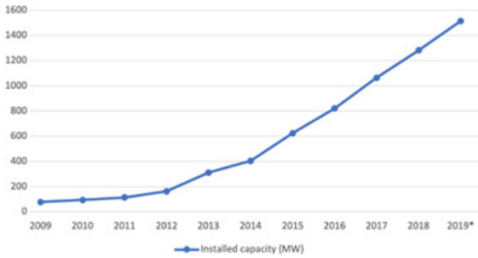
Geothermal

Since 2005 Turkey has intensified its exploration efforts for geothermal resources and has achieved some notable progress. According to the Ministry of Energy and Natural Resources, Turkey's geothermal potential is estimated at 35,500 MWth, and is mainly located in Western Turkey (78%); 10% of the total potential may be suitable for electricity generation. In 2018, some 1.954 Mtoe geothermal energy was directly used for the heating of buildings, in agriculture, in industry and in health tourism and 6.389 Mtoe for electricity generation (ETKB, 2019).

The 2023 Goals released in 2010 were targeting 600 MWe installed geothermal capacity. Later this capacity was revised to 1.000 MW in the Renewable Energy Action Plan. The Strategic Plan 2015-2019 set a target of 700 MW for 2019. The installed capacity of geothermal electricity generators exceeded both targets and at the end of 2019 it had reached 1.514.7 MW spread between 54 plants (Turkish Electricity Transmission Company, January 2020).

Figure 5.322 shows the development of the electric generation capacity from geothermal sources in Turkey.

Figure 5.322 **Installed electricity capacity of geothermal generation plants in Turkey**



Source: Turkish Electricity Transmission Company TEİAŞ, (*) preliminary figure.

Energy Efficiency and Cogeneration

(a) National targets

The first ever regulation for energy efficiency in Turkey was issued on 3 November 1977 and five additional energy efficiency regulations followed until the year 2000. The last one on "Thermal Insulation Rules in Buildings Standard" TS 825 from 2000 was revised in May 2008. The Energy Efficiency Law No. 5627 adopted in 2007 and Energy Efficiency Strategy issued in 2012 were major milestones in the effort to promote efficient use of energy and to reduce the country's energy bill.

The 2015-2019 Strategic Plan of the Ministry of Energy and Natural Resources contains two energy efficiency goals under "Theme 2 - Energy Efficiency and Energy Savings". Those goals are "Goal 4: A Turkey that Uses Energy Efficiently" and "Goal 5: Developed Capacity for Energy Efficiency and Saving". In conformity with the above-mentioned policy documents the National Energy Efficiency Action Plan 2017-2023 was prepared and published in the Official Gazette in 2017. The Action Plan aims towards effective implementation and monitoring of the national energy efficiency actions to achieve the goals. The National Energy Efficiency Action Plan was prepared in compliance with the template set in EU's Energy Efficiency Directive of 2012/27/EU.

The main objective of the National Energy Efficiency Action Plan is 23,9 Mtoe cumulative reduction of Turkey's primary energy consumption in the period of 2017-2023. According to the Ministry of Energy and Natural Resources this means decreasing the primary energy consumption of Turkey by 14 % in 2023 compared to the base case scenario. The plan aims to reduce the energy intensity of Turkey until 2023 by 20% compared to 2011. The Plan foresees 55 actions in 6 areas. Those areas are 1. Buildings and Services Sector, 2. Energy Sector, 3. Transport Sector, 4. Industry and Technology Sector, 5. Agriculture Sector and 6. Cross-cutting (horizontal) Areas. Expected savings, according to the National Energy Efficiency Action Plan by 2033, is 30.2 billion USD (Table 5.261)

Table 5.261 **Total Investments and Projected Savings from Energy Efficiency Projects in Turkey**

Total Investment Required (million USD)							
2017	2018	2019	2020	2021	2022	2023	TOTAL

Source: National Energy Efficiency Action Plan 2017-2023, Ministry of Energy and Natural Resources.

"Buildings' Energy Performance Regulation" and "Green Buildings Regulation" are other recent legislation issued in 2017.

(b) Incentive-based initiatives in the building sector (planned or already in place)

Since 2009 the Ministry of Energy and Natural Resources is supporting energy efficiency projects with incentives and The Ministry of Environment and Urbanization helps to rebuild the old building stock, according to the new regulations.

Efficiency Improvement Project (EEIP)

An industrial company with a minimum of 1,000 toe of annual energy consumption can apply and receive up to 30% grant for an EEIP less than 1 million TL investment.

Voluntary Agreements Program (VAs)

Eligible for such support are companies with a minimum of 1,000 toe of annual energy consumption targeting a minimum of 10% decrease in energy intensity over a three-year period. Companies meeting the agreed target may receive up to 20% of the energy costs during the first year up to 200,000 TL. Companies may apply and receive grants for the EEIP implementation and the Voluntary Agreements at the same time. Despite other interpretations both incentives target the industrial sector.

Transformation of Areas Under Disaster Risk

"Law of Transformation of Areas Under Disaster Risk" (No. 6306) and "Implementation Regulation" also contributes to Turkey's energy efficiency efforts. Large areas of Turkey are earthquake prone. Many of the multi-storey apartment buildings erected prior to the devastating Marmara earthquake of 1999, especially in 1970's are in bad shape and will not survive the next strong earthquake. In the framework of Law No.6306 the Ministry of Environment and Urbanization (MEU) supports an Urban Transformation Process in those areas. The Law encourages property owners to rebuild old risky buildings according to the new building standards and supports them with incentives such as rent allowance, credit facilities, move allowance, tax and fee immunities. The rent allowance to property owners is paid for 18 months and in 2019 amounted to 1,150 TL per month in metropolitan areas like Ankara, Istanbul and Izmir. Urban Transformation Process serves energy efficiency efforts in the buildings sector since the new buildings not only comply with earthquake regulations but also with new energy efficiency standards. According to the MEU from 2012 until August 2019 a total number of 1.166.000 dwellings applied for the urban transformation process and 11 bill TL have been paid to property owners and municipalities.

In 2019 MEU announced the Urban Transformation Action Plan with actions under eight topics. According to the Action Plan, 1.5 mill dwellings (300,000 per year) will be demolished and rebuild until 2023 in line with new standards. Topic 8: 'Financial Support to Urban Transformation with new Grants, Incentives and Loan Facilities' aims at supporting Urban Transformation Projects with higher energy performance targets with additional grants and loans.

(c) EU or non-EU funded energy efficiency programmes in the building sector

Turkish Residential Energy Efficiency Financing Facility TuREEFF

TuREEFF is a programme developed by the EBRD (European Bank of Reconstruction and Development) and supported by CTF (Clean Technology Fund) and the EU that aims to provide finance to residential property owners and investors who want to invest in Energy Efficiency projects in their buildings. Launched in 2015, TuREEFF is combining 270 million dollars of EBRD and CTF loans to promote a transition to Energy Efficiency lending by the local banks. The loan facility is complemented by an EU funded technical assistance program. The interested borrowers receive help from an expert team to develop Energy Efficiency projects and to prepare loan applications free of charge. Financing and advice are available via four participated financial institutions Şekerbank, Işbank, GarantiBBVA and YapıKredi. Until 2019 TuREEFF supported about 4500 projects and achieved 29.3 GWh/year primary energy and 7,393 t/year carbon savings (TuREEFF,2020).

Energy Efficiency in Public Buildings in Turkey

Launched under the German Climate Technology Initiative (DKTI), the project aims to improve the legal, technical and administrative framework conditions for energy efficiency in public buildings in Turkey in order to reduce their energy use and to comply more closely with EU energy efficiency standards. The project is commissioned by the Federal Ministry for the Environment, Nature Conservation and Nuclear Safety (BMU) of Germany. From the Turkish side the Ministry of Environment and Urbanisation (MEU) is the Lead executing agency. The overall term of the project was the period between 2014 and 2020. Since the beginning of the programme a large number of engineers and architects were educated in Train-the-Trainer programmes on Energy Performance Certificates in Turkey and its newly developed software. Several energy audits in public buildings with a focus on public schools were carried out. An innovative combined energy efficiency and earthquake-safety retrofit design for a public school was carried out. An energy efficiency data management system (DMS) for public buildings in Turkey is under implementation. An Energy Efficiency Technology Atlas on energy efficiency products, services, actors in various sectors in Turkey was prepared and launched (GIZ, DKTI Programme for ENERGY EFFICIENCY IN PUBLIC BUILDINGS in Turkey).

Technical Assistance for Renewable Energy and Energy Efficiency Support for the Municipalities and Universities - YEVDES

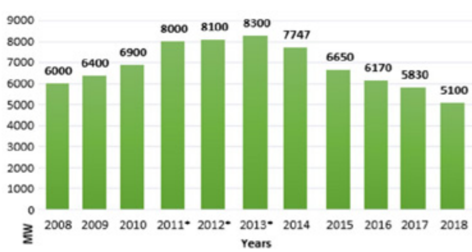
EU founded project IPA 2015 TR2015/EN/07/A1-02/001 with a budget of 4.499.520,00 EUR which was launched in March 2019 and has a duration of 30 months. Next to capacity building, the project will support feasibility studies for renewable energy, energy efficiency audits and R&D projects (YEVDES).

(d) Cogeneration: Regulatory framework, installed capacity

The legal framework for cogeneration or combined heat and power (CHP) facilities in Turkey is set by Law No.3096 enacted in 1984 allowing private companies to generate electricity and the Regulation No. 9799 for "Auto production of Electricity" from the year 1985. After a long period of uncertainties and capacity building efforts, the cogeneration investments started to boom in the second half of 1990's and the installed capacity of 4 MW in 1992 reached 2734 MW in the year 2000 and 6900 MW in 2010.

With the enactment of the new Electricity Market Law No. 6446 in 2013 the Auto producer model was abolished. The existing cogeneration facilities operating under an Auto producer licence had to apply for an Electricity Generation licence but kept their rights from the old law. Four Actions of The National Energy Efficiency Action Plan are now dealing with the promotion of cogeneration facilities. The installed capacity of cogeneration facilities in Turkey reached its zenith in 2013 with 8300 MW. Since then, the installed CHP capacity has been decreasing (Figure 5.323). The reason for this development may be lack of incentives and relatively high natural gas prices compared to electricity prices (Energy and Cogeneration Report 2018).

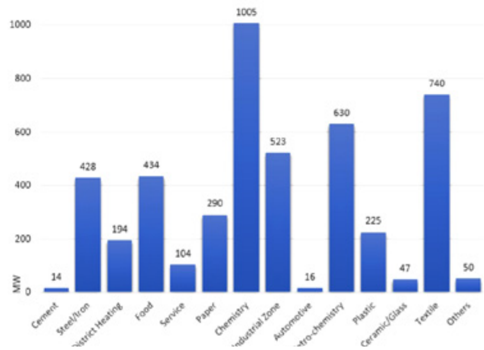
Figure 5.323 **Development of installed CHP capacity in Turkey over 2008-2018**



Source: Energy and Cogeneration Report 2018.

According to a recent legislation change, investors are allowed to build renewable energy and cogeneration facilities up to 5 MW in "non-licensed" status. Nearly half of the licensed cogeneration capacity is installed in chemical, petro-chemical and textile plants followed by food, iron & steel and plastics industries (Figure 5.324).

Figure 5.324 **Installed cogeneration capacity by sector in Turkey**



Source: Energy and Cogeneration Report 2018.

(e) Planned new projects

According to the Turkish Cogeneration Association 38 cogeneration and trigeneration plants with a total installed capacity of 117.9 MW were commissioned in 2019. We may expect a continuation of this trend in the coming years (Kojenerasyon Bülteni). According EPDK, there were 20 cogeneration facilities in the construction phase (Electricity Investment Realization January 2020, Energy Market Regulatory Authority EPDK). Installed capacities and investment in cogeneration plants are counted according to the fuel used.

Energy Investments Outlook

Due to the downturn of the economic growth during 2018-2019 many investors are postponing or cancelling some of their energy projects. They will surely develop new projects when the economy recovers and Turkey returns to high economic growth like in the past.

Oil sector

Turkish Petroleum Corporation TPAO will intensify its offshore exploration investments in the Black Sea and in the Mediterranean in the coming years. On January 31, 2020, TPAO acquired a third drill ship. One of the

5

three drill ships will operate in the Black Sea. In 2018, TPAO realized 688 mil $ investments in Turkey and 863 mil $ abroad (TPAO Sector Report 2018). But not all of this investment went into exploration and production (E&P). There is some correlation between the crude oil prices and oil and gas E&P investments in Turkey (Investment Opportunities in Turkey E&P Sector, 2019). In 2018, with an average Brent price of 71 $/bl E&P investment climbed to 540 mill $. With lower crude oil prices, we may expect a decrease of E&P investments in Turkey. With an average Brent price around 50-60 $/bl for the 2020-2030 period we may expect yearly E&P investments of around 400-500 mill $/year and a total investment of around 5 bill $. Half of this sum may be spent on oil exploration and production and the remaining for natural gas.

The refinery project of Çalık Holding in Ceyhan in the Mediterranean coast unveiled in 2006 has not been realized and a new attempt is not expected any time soon. Turkey's Wealth Fund announced a plan to invest 10 bil $ in a new refinery and petrochemical facilities in Ceyhan in the Mediterranean coast. The investment should start after the finalization of the preliminary studies in 2021 (Turkchem, January 2020).

TÜPRAŞ finalized the large modernization plan at associated investments of its refineries prior to the commissioning of the competitor STAR refinery. In 2019, the company invested 236 mill $. We may expect that the yearly investments will be reduced to 150-200 mill $/year to be invested in digitalization, logistics, sustainability and smaller competitiveness increasing projects. We may forecast a total investment by TÜPRAŞ during 2020-2030 period of some 1.8 bill $. Storage capacity upgrades of the STAR refinery, the RUBIS Dörtyol oil terminal and TPAO in Batman will be realized in coming years. For the 2020-2030 period a total of 300 mill $ in storage and terminal investments can be forecasted for actors other than TÜPRAŞ. Fuel distribution and retail sector is continuously investing in modernization and digitalization; their investment may reach 300 mill in $ in the 2020-2030 period. Total investments in the oil sector for the 2020-2030 period may sum up to 15 bill $.

Natural Gas infrastructure and upstream investments

In the 2020-2024 period BOTAŞ plans to invest 28.8 bill TL in transmission lines, in FSRU and underground storage. The largest investment will be the Tuz Gölü underground storage expansion with 19.3 bill TL. Assuming that the large investments will be realized within the foreseen budget and timeframe, in 2025-2030 period we may expect a reduction of BOTAŞ investments to 10 bill TL or even less. In the 2020-2030 period, we may expect yearly distribution investments around 1 bill TL. The total investments in 2020-2030 may sum up to 48 bill TL + 2.5 bill$ for E&P.

Electricity Generation, Transmission and Distribution

Assuming that the Turkish Electricity Transmission Company TEİAŞ maintains its yearly investment volume we may expect investments of about 40 bill TL in the 2020-2030 period. Public electricity generation company EÜAŞ will mainly invest in the rehabilitation of existing coal and hydro powerplants and start with the erection of the 6.3 bill TL Gökçekaya Pumped storage power plant. We can forecast a total investment of about 10 bill TL until 2030.

Regional electricity distribution companies will finalize their investment commitments in 2020 and reduce their yearly investments. We may forecast a total of 10 bill TL investments until 2030. The focus of the investments will be the reduction of distribution losses, smart grids, remote metering and smart electricity meters. To commission **12 coal fired power plants** with 8,200 MW in construction phase until 2030 an investment of 12 bill $ is needed. Assuming further delays or cancellations due to environmental or financial issues, we may assume a total of 8 bill $ investment in new power plants.

21 natural gas fired power plants and cogeneration facilities with 3,535 MW capacity are in the construction phase. Some of the larger generation projects may be further delayed or cancelled and many new cogeneration projects may be added. An estimated investment of 2.5 bill $ will be needed to commission the natural gas fired power plants and cogeneration facilities until 2030. A total of 8,356 MW **wind projects** including 2,000 MW from 2 YEKA auctions are in different stages of development. If the successor model of YEKDEM feed-in tariff offers favourable conditions to investors and new YEKA auctions take place in the coming years, we may expect about 12,000 MW new wind capacity to be commissioned until 2030 with 11 bill $ investment. In a negative scenario the wind investments may barely reach 9,000 MW until 2030.

The **solar PV** investment boom, driven by unlicensed distributed generation projects may continue. We may also expect the realization of YEKA auction projects. With 11 bill $ investment, the installed capacity may reach 17,000 MW in 2030. If the favourable investments conditions continue, the **geothermal electricity generation** potential of approximately 3,500 MW can be realised until 2030. This will trigger about 5 bill $ investment until 2030.

We may also expect about 700 MW new biomass generation capacity in 2020-2030 period and the total installed capacity of biomass plants may reach 1,500 MW in 2030 with an investment of 2 bill $. Taking 1.2 bill TL yearly hydropower sector investment of DSI as a reference and applying a conservative scenario, we may expect a total investment of the public agency until 2030 of 10 bill TL. This may enable the commissioning of 1,758 MW capacity under construction and to start with new projects of around 600-700 MW. With a reduced risk appetite, the private sector may barely commission 1,878 MW under construction by investing around 4 bill TL until 2030 and increasing the forecast for 2020-2030 period to 14 bill TL.

Akkuyu NPP, the first commercial **nuclear power** plant to be built in Turkey is implemented in accordance with the Intergovernmental Agreement concluded between the Government of the Russian Federation and Government of the Republic of Turkey on May 12, 2010. The project has an estimated CAPEX of 20 billion USD and an operating period of 60 years. The project will be developed, financed, operated and decommissioned by Akkuyu Nükleer A.Ş., owned by Rosatom. The Turkish side guarantees the purchase 50% of the generated electricity within the first 15 years at a price of 12.35 US cents/KWh. Developer of the Akkuyu NPP project tries to fasten the construction of the first unit in order to start electricity generation end of October 2023.

According to their original timetable the first unit would be inaugurated in 2025, followed by remaining units in 2026, 2027 and 2028. In 2019 the foundation of the first unit has been build and some of the equipment like core catcher were delivered to the site. The company started with the site preparation of the second unit during the last days of 2019 (Akkuyu Nuclear A.Ş.). The experts estimate a 15-20% realization of the construction of the first unit by the end of 2019. Based on the construction progress of the first unit in Akkuyu we may expect that remaining investment of the project of around 19 billion USD will take place in the 2020-2028 period.

For the second nuclear power plant project in Sinop, an Intergovernmental Agreement has been signed with Japan in October 2013. Sinop NPP was planned to have ATMEA-1 type reactor design with 4x1120 MW units. Project developers, led by Mitsubishi Heavy Industries finalized their feasibility study in 2018. The studies showed a high cost increase s. The Turkish side cancelled the Sinop NPP project in 2019. A new attempt for the realization of the second nuclear power plant in Sinop with another investor group may start in the coming years but there are no official announcements from the government as yet. But EÜAŞ is planning to realize some minor infrastructure investments for Sinop NPP site for 62.5 mill TL. There are no new developments regarding a third NPP project near İğneada in the Thrace region. Originally Chinese companies were interested in this project.

The total **forecasted energy investment** for the period 2020-2030 in Turkey sums up to 76 bill $ plus 112 bill TL.

The Peripheral Countries

The Peripheral Countries: Azerbaijan, Austria, Moldova, Ukraine, Italy, Slovakia, Syria, Lebanon and Egypt

There is a group of countries, surrounding our 15 country core group, which we have termed as peripheral countries. These countries are important to the present "Outlook" study as they are associated, in terms of direct energy flows but also trade links, with our specific region. Each of these countries, for different reasons each, is important as they influence energy related developments and issues in the various countries of the broader region. As the name implies these peripheral countries are the ones which literally surround our core region and include Azerbaijan, Austria, Moldova, Ukraine, Italy, Slovakia, Syria, Lebanon and Egypt. There are certain other countries, such as Jordan, which although close and neighbors to our core country group, do not have an immediate bearing in terms of energy impact to our region and hence they have not been included in our present examination.

Following the in-depth analyses in the energy sector of 15 SEE core countries, this Chapter attempts a synopsis of the energy profiles and key energy issues of the aforementioned peripheral countries. The peripheral countries are important for different reasons each. For instance, Syria and Ukraine are countries with substantial geopolitical interest that may affect energy security of supply in SE and Central Europe, while Italy also plays an important role as it acts as an integral part in several regional energy projects, including, for instance, the gas interconnector Greece-Italy (IGI), the Trans Adriatic Pipeline (TAP) and the electricity interconnectors Italy-Montenegro and Italy-Slovenia. Then, we have Azerbaijan, which is a major oil and gas exporter to our 15-country core group and hence merits our attention.

In addition, Azerbaijan's gas flows reached for first time in history the European gas markets from January 1, 2021 through the TAP-TANAP system.

Azerbaijan

According to the IEA (1), Azerbaijan has undergone significant economic transformation since its independence in 1991, with its large oil and gas reserves enabling its strong growth in the 1990s and 2000s. However, heavy dependence on extractive industries has left Azerbaijan exposed to the negative effects of oil price volatility.

From 2013 2017, its GDP growth averaged 1.4% per year, down from 5.5% during 2008 2012. The country's hydrocarbon sector was responsible for the bulk of the decline, as it contributes roughly a third of GDP and makes the bulk of its exports. The 2014/2015 sharp drop in global oil prices and the ensuing decline in oil production pushed this contraction. In addition, the oil price drop led to a decline in remittances from Azerbaijan's hydrocarbon-rich trading partners. These remittances, the bulk of which support the country's rural population, fell by one-third. In 2017, Azerbaijan's GDP barely saw any growth, but 2018 experienced an increase of 1.4%, based on IEA's data. Oil and gas account for more than 90% of Azerbaijan's exports. Oil and gas production increased considerably in the 2000s, following discovery of the Shah Deniz gas field, to reach record levels in 2010. The government and international companies have invested substantially in the energy sector and the construction of several new power plants as well as rehabilitation and modernisation of the gas and electricity networks have improved reliability and security of supply.

Azerbaijan has also strong potential for renewable energy development. The country has excellent solar and wind resources and significant prospects for biomass, geothermal and hydropower. Practical deployment has been limited, however, compared with the scale of the country's available resources and long-term ambitions.

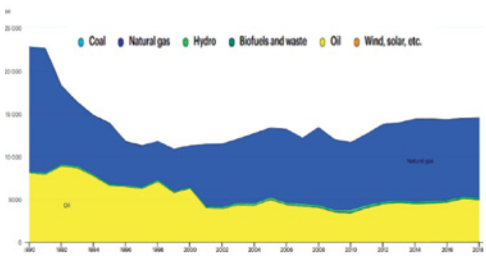
6

Renewables also offer the most prominent low-carbon solution to meeting Azerbaijan's climate targets. The country has committed to reducing its greenhouse gas (GHG) emissions by 35% by 2030, measured from the 1990 base year set in its nationally determined contribution (NDC) under the Paris Agreement, which emphasises the use of alternative and renewable energy sources to achieve this target. Despite widespread privatisation of the economy since the country gained its independence, the energy sector in Azerbaijan remains predominantly government-controlled. Only a handful of small hydropower plants are in private ownership, and they account for less than 1% of electricity generation.

Energy Supply, Demand and Exports

Azerbaijan's energy demand, measured by total primary energy supply (TPES), was 14.4 million tonnes of oil equivalent (Mtoe) in 2018. The country is a major crude oil producer (37.5 Mt, including natural gas liquids in 2019) and a significant producer of natural gas (24.5 bcm in 2019). Azerbaijan was the 24th largest crude oil producer in the world in 2018. Because of this large hydrocarbon production, it has one of the highest energy self-sufficiency ratios in the world: its energy production is more than four times its energy demand. Azerbaijan generates 26 TWh of electricity annually, mostly from natural gas (more than 90% in 2019). Azerbaijan's sole refinery produces 5.8 Mt of oil products from domestic crude oil and NGLs.

Figure 6.1 **TPES by Source in Azerbaijan, 1990-2018**

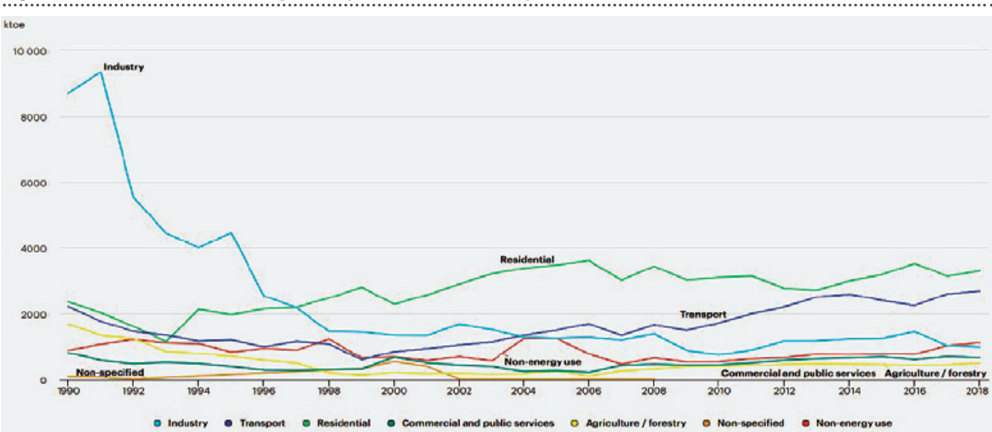


Source: IEA

In 2018, Azerbaijan's total final consumption (TFC), excluding transformation sector, was 9.2 Mtoe. The residential sector is the largest final consumer (3.3 Mtoe in 2018), while transport is the second-largest final-energy-consuming sector (2.7 Mtoe in 2018). Most oil products consumed in the transport sector are produced in Azerbaijan. Despite natural gas having the largest share in the country's TPES, oil is the main fuel in TFC, with a 45% share in 2018. This is because most natural gas is consumed to generate electricity and heat.

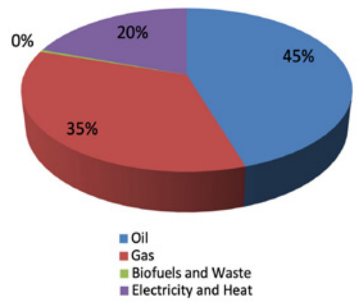
Renewables, including hydro, contributed 2% to total primary energy supply, about 0.4% to total final consumption and 8% (2 TWh) to electricity supply in 2018.

Figure 6.2 **Total Final Consumption by Sector in Azerbaijan, 1990-2018**



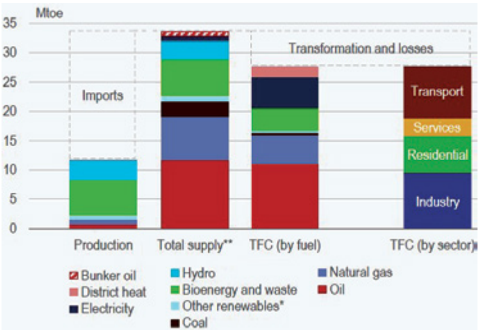
Source: IEA

Figure 6.3 **Total Final Consumption by Source in Azerbaijan, 2018**



Source: IEA

Figure 6.4 **Overview of the Austrian Energy System by Fuel and Sector, 2018**



Source: IEA

As of December 31, 2020, Azerbaijan started exporting gas to the European Union via the TANAP pipeline to Turkey and the Trans Adriatic Pipeline (TAP), as the region seeks to diversify energy supplies away from Russia. More specifically, gas pumped from the giant Shah Deniz 2 field in the Caspian Sea began flowing into Italy, Greece, and Bulgaria on December 31, Azerbaijan's state energy company SOCAR said in a statement. Azerbaijan already supplies gas to Turkey and aims to supply European gas markets with 10 bcm of gas per year. In general, Azerbaijan is an exporter of crude oil and a net exporter of petroleum products, natural gas and electricity.

Austria

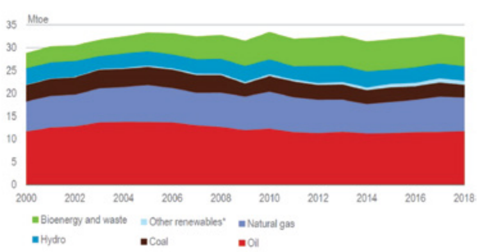
According to the IEA (1), Austria is heavily dependent on energy imports, despite its large hydro and bioenergy resources. Its average self-sufficiency level has been 36% over the past decade, characterised by a high and continuously increasing share of renewable energy sources. Total primary energy supply (TPES) was 32.8 million tonnes of oil equivalent (Mtoe) in 2018, of which fossil fuels accounted for around two-thirds and renewables for the remaining third (see Figure 6.4).

Total final consumption (TFC) by fuel was 27.6 Mtoe in 2018, of which oil accounted for 40%, electricity for 20%, natural gas 18%, and bioenergy and waste 14%. By end-use sector, TFC is split between the industry sector, transport and buildings (the residential and service sectors including agriculture), with roughly a third of consumption each. Renewable energy is especially large in electricity generation, where hydropower accounts for over half of the total, with continuously increasing shares of wind and solar.

Primary Energy Supply

In 2018, oil accounted for 36% of TPES, natural gas for 23% and coal for 8%. The remainder was low-carbon energy sources, in particular bioenergy and waste, which accounted for 19% of TPES, and hydro with 10% (see Figure 6.5). Small shares of solar, wind and geothermal accounted for the remainder.

Figure 6.5 **TPES by Source in Austria, 2000-2018**



Source: IEA

Since 2000, there has been a continuous shift to renewable energy sources. Among renewables, bioenergy and waste increased the most in terms of absolute numbers, from 3 Mtoe in 2000 to 6 Mtoe in 2010. Since then, however, the share of bioenergy and waste supply has been stable. Wind and solar energy have increased about threefold over the last decade, and their share of TPES grew from below 1% in 2008 to nearly 3% in 2018. Meanwhile, coal supply fell by 28%, from 3.8 Mtoe in 2008 to 2.7 Mtoe in 2018. Oil supply decreased by about 7%, from 12.7 Mtoe in 2008 to 11.8 Mtoe in 2018, but remained the single largest fuel in TPES, while natural gas supply fluctuated between 6.4 Mtoe and 8.1 Mtoe during the same period, based on IEA's data.

Energy Production and Self-sufficiency

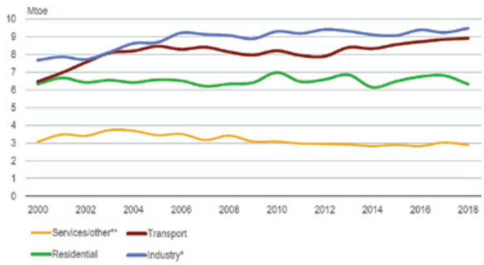
In 2018, domestically produced energy was 11.7 Mtoe, of which 51% was bioenergy and waste, followed by 28% of hydro. Fossil fuels accounted for only 13% of domestic production in the same year and the trend is declining. Crude oil production fell by 30%, from 1.0 Mtoe in 2008 to 0.7 Mtoe in 2018 . Similarly, domestic natural gas production fell by 30% (32% in volume terms), from 1.2 Mtoe in 2008 to 0.9 Mtoe in 2018, following a peak in 2012 at 1.5 Mtoe.

Energy Consumption

Energy consumption has been on an upward trend in the industry and transport sectors since 2014, while fluctuating in the residential sector (see Figure 6.6). Austria will likely miss its total final energy consumption target for 2020. TFC increased from 26.4 Mtoe in 2014 to 27.9 Mtoe in 2017, which was the highest consumption level in Austria so far. In 2018, TFC fell slightly to 27.6 Mtoe, due to a drop in the residential sector after a previous increase. Consumption in the residential sector depends largely on the need for heating, and it has fluctuated between 6 Mtoe and 7 Mtoe over the last decade.

The transport sector has seen the largest increase in recent years, from 7.9 Mtoe in 2012 to 8.9 Mtoe in 2018. Industrial consumption, including non-energy consumption, has also increased, although slowly, to a new high at 9.5 Mtoe in 2018. Meanwhile, consumption in the service sector has remained stable at around 3 Mtoe in the last decade.

Figure 6.6 **Total Final Consumption by Sector in Austria, 2000-2018**



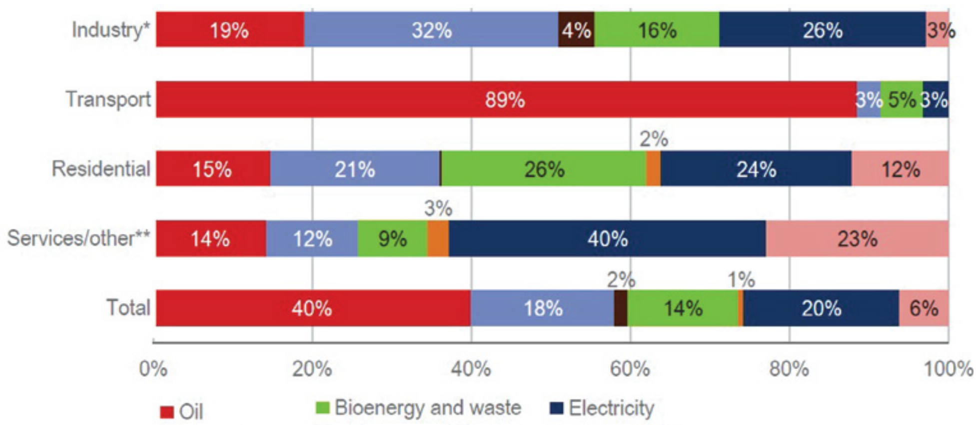
Source: IEA

Fossil fuels accounted for 60% of TFC in 2018, as shown in Figure 6.7. The transport sector is highly dependent on oil, which accounted for 89% of the sector's total energy consumption. The industry sector is also heavily dependent on fossil fuels, which supplied 55% of total fuels consumed in industry, including for non-energy purposes. Of this, natural gas accounted for the largest portion, with 32%, followed by 19% of oil and 4% of coal. Almost all coal consumption in Austria is in the industrial sector. Electricity, bioenergy and waste are also important energy sources in industry.

In the residential and service sectors, energy is mainly used for heating or electrical appliances. Both the residential and the service sector use natural gas and oil for heating purposes, but bioenergy is the largest source of heat in residential buildings, while district heating the largest source of heat in the service sector.

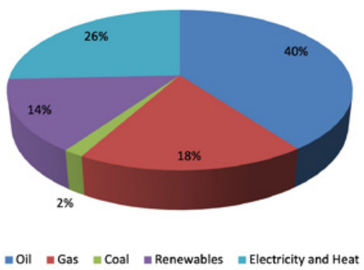
1 These numbers are in energy terms for the production of crude oil, including natural gas liquids and feedstock.

Figure 6.7 **Total Final Consumption by Source and Sector in Austria, 2018**



Source: IEA

Figure 6.8 **Total Final Consumption by Source in Austria, 2018**



Source: IEA

As far as energy flows are concerned, electricity in Austria is exchanged freely between Germany, the Czech Republic, Switzerland, Hungary, Slovenia and Italy, with Austria being a net importer of electricity. In addition, Austria's gas market depends largely on imports from other countries, such as Russia, Norway and Germany. This is clearly reflected in the ratio of the country's annual gas production of 0.9 Mtoe and net imports of 6.5 Mtoe, amounting to a gross consumption of 7.8 Mtoe in 2018. In 2018, a total of 9.1 Mtoe of crude oil was processed at a capacity utilization of 91%. 7% of the crude oil processed came from domestic sources and 93% from imports, mainly from Kazakhstan, Libya and Iraq.

Moldova

According to the IEA (2), Moldova lacks energy resources and thus, it is almost wholly dependent on fossil fuel and electricity imports: only 20%[2] of its energy demand was met by domestic sources in 2018. Natural gas, which serves most of its energy needs, was entirely imported from Russia via Ukraine up to the end of 2014. In August 2014, the Iasi-Ungheni gas interconnector between Romania and Moldova was commissioned, and became operational in 2015. Once at full capacity in 2020, the pipeline is expected to supply almost all the gas Moldova consumes, but not that of the Transnistria region. The government also plans to diversify the energy mix with more renewable energy. As expansion requires significant investment in the medium and long term, progress will depend on the country's ability to attract funds. The development of uncontrollable renewables, such as wind and solar, will be limited by the balancing capabilities of the Moldovan power system.

Moldova has been a member of the Energy Community since 2010 and signed an Association Agreement with the European Union on June 27, 2014. It therefore had until December 2017 to make its legislation conform to the EU acquis communautaire, which is the core EU energy legislation related to electricity, oil, gas, the environment, competition, renewables, efficiency and statistics.

[2] This figure represents the IEA Secretariat's estimates for the districts from the left side of the river Dniester and municipality of Bender.

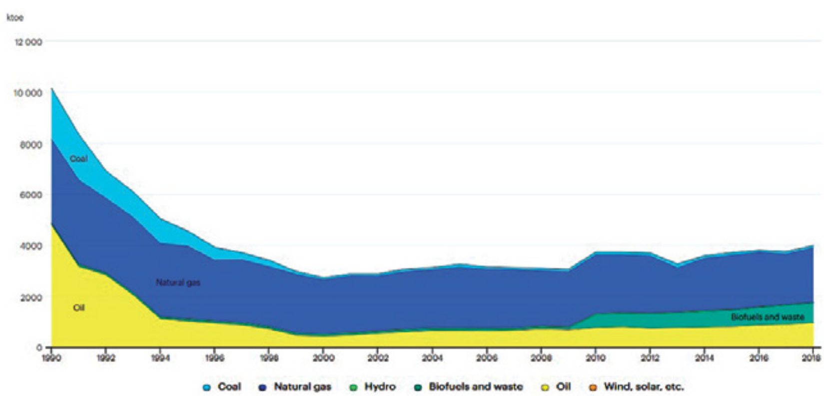
Moldova also plans to fully synchronise its electricity network with the European Network of Transmission System Operators for Electricity (ENTSO-E) to connect to the European electricity market. Regional energy co-operation with Caspian and Black Sea countries and the European Union follows the framework of the Baku Initiative, which aims to facilitate the progressive integration of the region's energy markets into the EU market, as well as the transportation of substantial quantities of Caspian oil and gas towards Europe. Moldova also participates in the Eastern Partnership, a joint initiative involving the European Union, its member states and the post-Soviet states of Armenia, Azerbaijan, Belarus, Georgia, Moldova and Ukraine; it provides a venue for discussions on trade, economic strategy and travel agreements, as well as an energy security platform. In addition, the European Neighbourhood Policy promotes bilateral co-operation between the European Union and Moldova in line with the Partnership and Co-operation Agreement, which includes energy co-operation. Based on IEA's data[3], Moldova consumes around 4 million tonnes of oil equivalent (Mtoe) of energy per year (4.1 Mtoe in 2018), comparable to energy consumption in Luxembourg.

Energy Supply, Demand and Imports

Moldova's energy self-sufficiency is very low, among the lowest in the world. Around 20% of its energy demand is covered by domestic production, consisting almost fully of solid biomass; total domestic energy production was 0.82 Mtoe in 2018, of which 0.79 Mtoe solid biofuels. Natural gas accounts for more than half of Moldova's total primary energy supply (53% in 2018), oil roughly a quarter (23% in 2018) and solid biomass one-fifth (19% in 2018). Most natural gas is used for electricity and heat generation[4] , whereas oil is the most important energy source for final consumers, mainly used for transportation. The residential sector is the largest energy consuming sector (around 1.4 Mtoe in 2018), solid biofuels covering over 50% of the sectorial consumption. Transport sector is the second-largest energy consumer (around 0.7 Mtoe) and the main driver in oil consumption growth.

Furthermore, Moldova needs to import most energy commodities to meet domestic demand. All natural gas consumption (2.1 Mtoe or 2.9 billion cubic metres (bcm) in 2018) is met through imports, mainly from Russia. Imports cover 99% of Moldova's oil consumption (1.0 Mtoe in 2018, of which almost 80% diesel and motor gasoline). All coal consumed must be imported as well (0.09 Mtoe in 2018).

Figure 6.9 **TPES by Source in Moldova, 1990-2018**

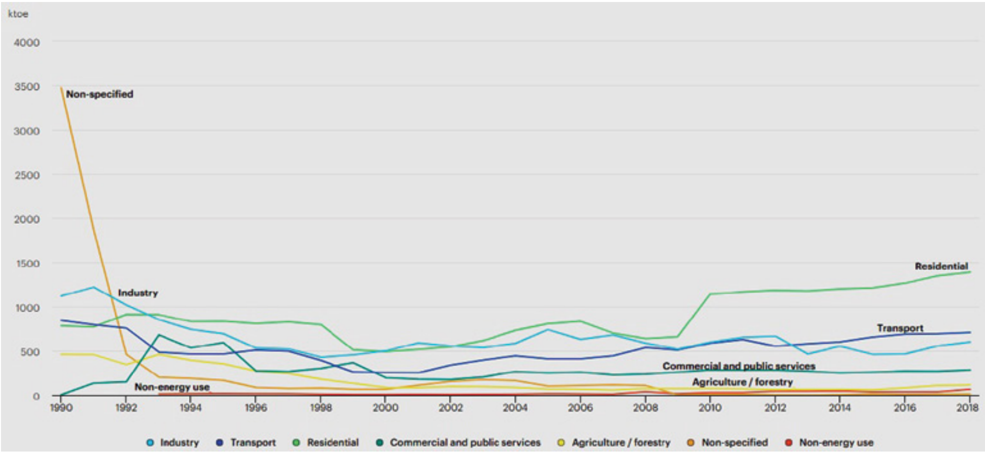


Source: IEA

[3] Official figures on natural gas imports, natural gas inputs to power plants, electricity production and consumption are modified by the IEA Secretariat to include estimates for supply and demand for the districts from the left side of the river Dniester and municipality of Bender.

[4] Natural gas is used at MGRES power plant, which is situated in Transnistria. The Moldovan government procures electricity directly from the plant.

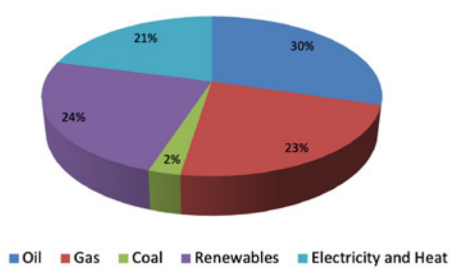
Figure 6.10 **Total Final Consumption by Sector in Moldova, 1990-2018**



Source: IEA

Renewables represent 20% of Moldova's energy mix, consisting almost fully of solid biofuels (19% in 2018). 6% of electricity generation comes from renewable sources (hydro, wind, solar PV), based on IEA's data.

Figure 6.11 **Total Final Consumption by Source in Moldova, 2018**



Source: IEA

Ukraine

Located at the crossroads of the European Union, Russia and the Black Sea and Caspian regions, Ukraine has abundant mineral resources including oil, natural gas and coal, and large hydro and biomass potential. With its considerable population and high energy consumption, it is one of Europe's largest energy markets. It is also the country that transits the most natural gas in the world, playing a key role in delivering Russian gas to European markets.

Deep structural changes and an overall decline in economic activity caused total gas consumption to fall from 50.4 billion cubic metres (bcm) in 2013 to 29.8 bcm in 2019 and caused natural gas's self-sufficiency[5] to increase from 43% to 69%. Also, during this period, a dispute with Gazprom over the price of gas and its transit through Ukrainian territory prompted Ukraine to source its imports from European suppliers instead, so Gazprom's share in total gas imports shrank from 92% in 2013 to 0% during 2016 2019. Coal production and transportation have been severely disrupted in the Donbass region, as has electricity generation from co generation plants[6] , especially in conflict areas.

Energy Supply, Demand and Imports

According to the IEA (3), Ukraine produces all fossil fuels (in 2018: 14.4 Mtoe of coal, 16.5 Mtoe of natural gas and 2.3 Mtoe of crude oil), but in quantities insufficient to meet total energy demand. Still, nearly 65% of Ukraine's total energy demand is covered by domestic

[5] Excluding the temporary occupied Autonomous Republic of Crimea, Sevastopol-City and parts of Donetsk and Luhansk regions.
[6] Domestic production/TPES.

production. This high self-sufficiency level is explained by nuclear power generation, as Ukraine is the world's seventh-highest producer (83 TWh in 2019). Over half of the country's electricity is produced with nuclear power and Ukraine and Armenia are the only EU4Energy countries that produce nuclear energy. Ukraine is the top energy consumer among EU4Energy focus countries. Its primary energy supply was 93 Mtoe in 2018, corresponding to around 90% of Poland's consumption.

In 2018, Ukraine's total final consumption (TFC; excludes transformation sector) accounted to 51.5 Mtoe. Industry is the largest final energy consumer (19.1 Mtoe in 2018). The residential sector is second (16.7 Mtoe), with households being the major users of natural gas (8.7 Mtoe in 2018). The share of coal in final consumption is very small (12%) because most of the coal consumed in the country is used to produce electricity and heat. Ukraine depends on imports for around 83% of its oil consumption, 33% of its natural gas and 50% of its coal. In 2018, Ukraine imported 8.5 Mtoe (10.6 bcm) of natural gas, 13.8 Mtoe of coal and 10.4 Mtoe of oil products. Belarus is Ukraine's main supplier of refined products. Ukraine's energy mix is relatively diversified, with no fuel representing more than 30% of the energy mix. In 2018, the share of coal (the country's primary fuel) dropped to 30%, followed closely by natural gas (28%) and nuclear (24%). Renewables accounted only for 5% of the energy mix in 2018, and for 9% of electricity generation (13.4 TWh in 2019).

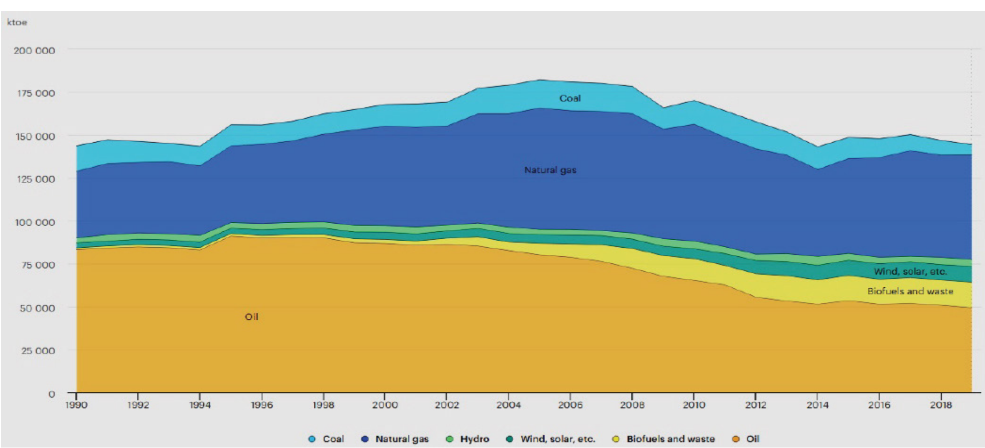
Italy

The last few decades have seen profound changes being made to the Italian energy system, in which natural gas first of all established itself as a prime energy source, followed by (from 2005 onwards) a marked rise in renewable energy sources, in particular in the electricity sector, and a steady reduction, on the other hand, of petroleum products. These developments are the results of both policies aimed at significantly reducing greenhouse gas emissions and thus combating the risks associated with climate change, and by the need to guarantee greater security and diversification in energy supplies, according to Italy's National Energy and Climate Plan. (4)

Energy Supply and Demand

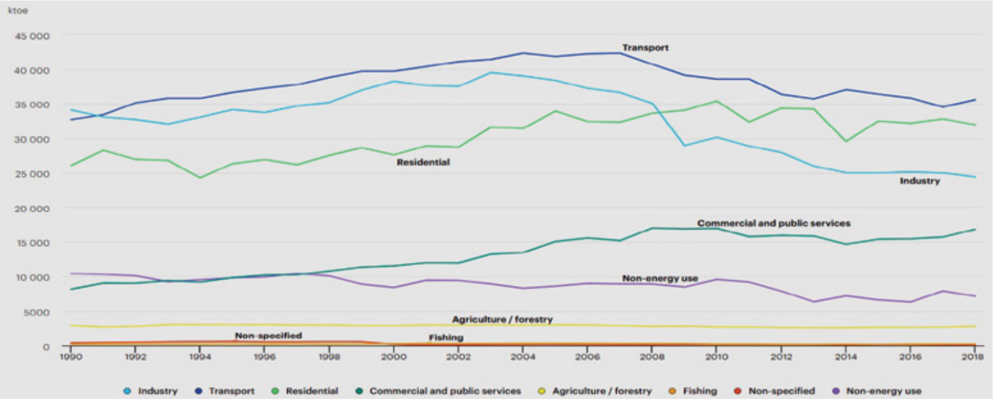
Based on IEA's data, Italy produced 34.7 Mtoe of energy in 2018, recording an increase of 5.6% from 2008 to 2018. The country's total primary energy supply (TPES) was 150.6 Mtoe in 2018, declined by 17.1% over the past ten years, down from 181.7 Mtoe in 2008 (see Figure 6.15). Fossil fuels accounted for 79% of TPES in 2018, broken down in natural gas (39.5%), oil (33.8%) and coal (5.7%). Renewables represented 18.5% of TPES in 2018, up from 36% ten years earlier. Gross inland consumption and final consumption levels fell dramatically in the 2005-2014 period, save for an upturn in 2010, followed by a slight drop in recent years. The fall in the consumption of petroleum products, natural gas and (albeit at an inconsistent rate) coal has been particularly marked. Over the last few decades, renewable energy sources, thanks to a generous scheme of incentives, have played a leading role in a period of significant development in Italy; this period ended in 2013, after which progress has been rather stagnant, with a fall being recorded in 2016. Italy's total final consumption (TFC) amounted to 119.1 Mtoe in 2018, representing around 79% of TPES, with the remainder used in power generation and other energy industries. TFC has declined by 14% from 2008 to 2018. Energy demand is split relatively equally between transport, households and industry. These sectors accounted for 29.9%, 26.8% and 20.5% of total final consumption in 2018 (see Figure 6.16).

Figure 6.15 **TPES by Source in Italy, 1990-2019**



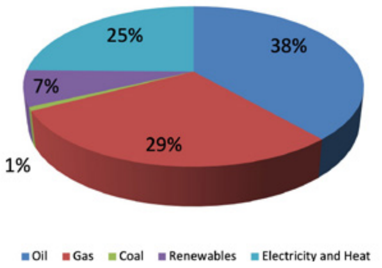
Source: IEA

Figure 6.16 **Total Final Consumption by Sector in Italy, 1990-2018**



Source: IEA

Figure 6.17 **Total Final Consumption by Source in Italy, 2018**



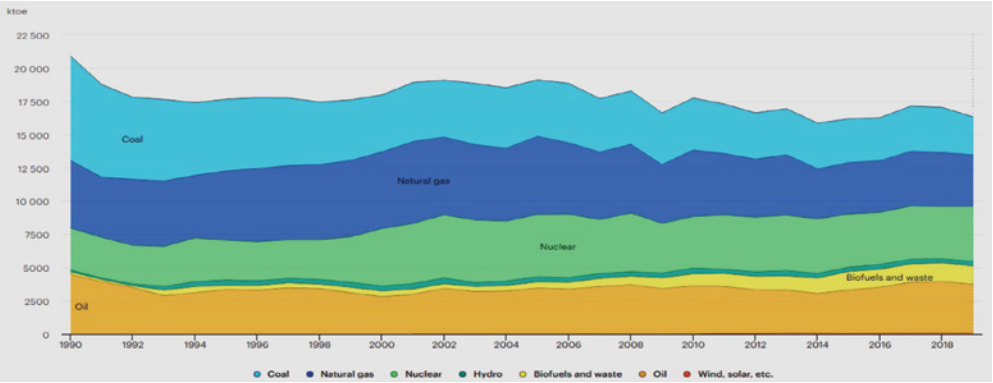
Source: IEA

As far as energy flows are concerned, Italy is a net importer of gas, mainly from Russia, Algeria, Qatar and Libya as well as a net importer of oil and petroleum products, mainly from Azerbaijan, Saudi Arabia, Iraq and Russia. In addition, Italy is a net electricity importer, with imports mainly coming from Switzerland, France, Slovenia, Austria and Greece.

Slovakia

Slovakia's energy system is characterised by a high share of nuclear power, which accounted for 62% of domestic energy production in 2018 and was also one of the largest parts of the total primary energy supply (TPES) (see Figure 6.18). Domestic nuclear energy production helps improve energy security in Slovakia, which otherwise is dependent on large fossil fuel imports, mainly from Russia.

Figure 6.18 **TPES by Source in Slovakia, 1990-2019**



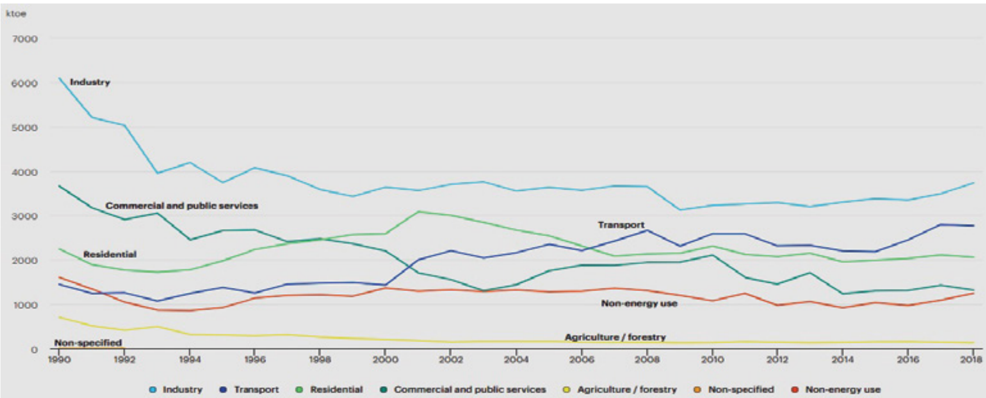
Source: IEA

Natural gas, oil and electricity are the main energy sources, which accounted for 79% of TFC in 2018. Natural gas and electricity are consumed across most sectors, with the largest demand in industry, whereas oil dominates in the transport sector. Slovakia also has an extensive district heating (DH) system, fuelled mainly with natural gas and, increasingly, biofuels, according to the IEA (6).

Energy Supply and Demand

TPES has varied around 15-20 million tonnes of oil equivalent (Mtoe) over nearly half a century. In the past decade, TPES has trended slowly lower, from 18.3 Mtoe in 2008 to 17.4 Mtoe in 2018. Nuclear power production began in the late 1970s and grew rapidly in the mid-1980s and early 2000s as new power plants were introduced. Over the past decade, nuclear energy has decreased slightly as a result of the closedown of two old reactors. Fossil fuel supply has declined more rapidly; from 12.9 Mtoe in 2008 to 11.4 Mtoe in 2018. In contrast, biofuels and waste more than doubled from 0.6 Mtoe in 2008 to 1.4 Mtoe in 2018. Biofuels and waste are mainly used for heat and power generation, or are consumed by industry.

Figure 6.19 **Total Final Consumption by Sector in Slovakia, 1990-2018**

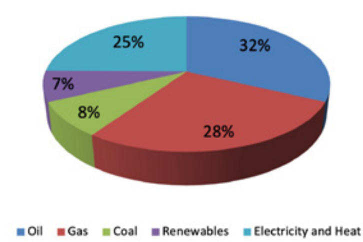


Source: IEA

Energy demand dropped sharply after the collapse of the Soviet Union in the early 1990s. Total final consumption stood at 11.2 Mtoe in 2018. Slovakia has a large industrial sector, notably a fast-growing automotive manufacturing industry, which has replaced some heavy industries from the Soviet era. Industry accounted for over 33% of TFC in the country in 2018, of which 21% was natural gas and oil products used for non-energy purposes in industrial processes. The remaining TFC was in the transport sector (25% of TFC), residential sector (18%) and commercial sector (12%). In 2018, oil was the dominant fuel in transport, whereas natural gas and electricity accounted for the largest share of TFC in other sectors. District heating was the second largest energy source in the residential sector after natural gas in 2018.

As far as energy flows are concerned, Slovakia is 100% relied on Russian gas imports and is a net importer of oil and petroleum products, mainly from Russia, Austria, the Czech Republic and Hungary. In addition, Slovakia is a net electricity importer, with imports mainly coming from the Czech Republic, Poland, Ukraine and Hungary.

Figure 6.20 **Total Final Consumption by Source in Slovakia, 2018**



Source: IEA

Syria

Syria is going through a difficult historical period and faces real challenges in how to meet its electricity demand. Due to the civil war, which this year entered its 10th year, and the control by several parties of its fossil fuel resources and its electricity grid, the country is facing lack of oil and gas production, oil companies shutting down, destruction of the electricity grid, insufficient conversion capacities and financial weakness of energy entities, halting imports, and giving rise to corruption.

Due to the civil war and ensued hostilities in several parts of the country, oil and electricity demand almost collapsed. This is expected to gradually increase as exiled population returns and production activities start again, giving impetus to the Syrian economy. However, the restoration of the national economy and its economic and social development require a sustainable, safe and effective energy sector. According to Jamil and Sidorenko (7),Syria is located within the sunbelt zone; it has about 300 sunny days with high solar radiation. There are many areas where the average annual wind speed exceeds 6 m/s. Highest average wind speeds detected in Sendiania, Barshin and other sites that are suitable for wind power generation.

In this respect, Syria has excellent climatological conditions, which could enable the large scale of renewable energy sources' utilization, especially solar thermal, solar PV and wind.

In Syria, the energy supply increased between 1991 and 2008 and then decreased dramatically once the civil war started in March 2011. In 2018, Syria's total primary energy supply reached 10.4 Mtoe (see Figure 6.21), registering a fall of 55% compared to the 2008 pre-war level. In 2001, oil production in Syria stood at 401,000 b/d (or 19.3 Mt), while in 2019 it had collapsed to 24,000 b/d (or 1.0 Mt).

In 2008, Syria became a net importer of natural gas, transported through the Arab pipeline, but the state of conflict in the country and the sanctions affected its ability to receive natural gas. Over the last years, Syria's primary energy supply has been secured through Iranian oil imports since due to sharp fall of its domestic oil production by more than 95% on average from 2011 until today, the country needs to import crude and oil refined products.

In 2018, Syria's total final consumption (TFC) reached 6.2 Mtoe, recording a fall of 59%, compared to 2008 level. The transport sector had the largest share (34.4%) of the country's TFC in 2018, followed by the residential (21.9%) and industrial sectors (21.3%), as shown in Figure 6.22.

Figure 6.21 **TPES by Source in Syria, 1990-2018**

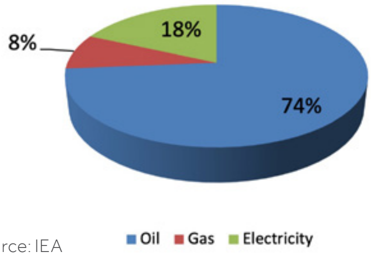
Figure 6.23 **Total Final Consumption by Source in Syria, 2018**



Source: IEA

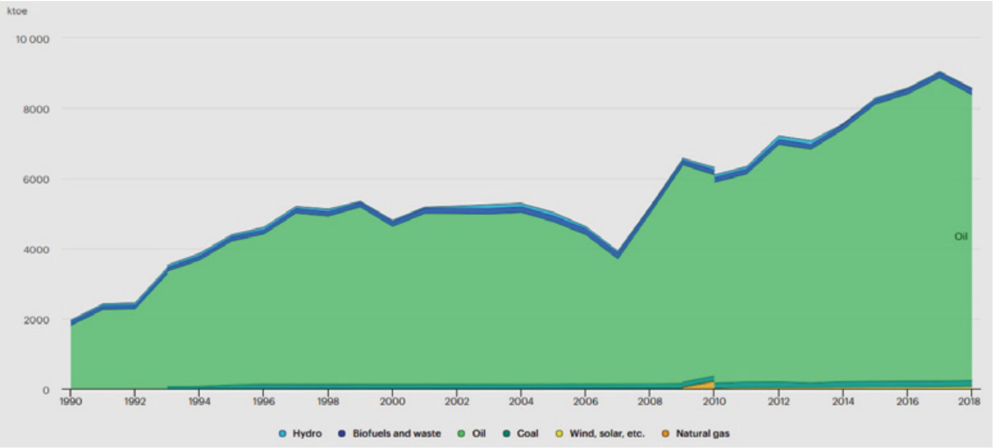
In Chapter 8 on "Hydrocarbon Exploration and Production" of this Outlook, some further discussion on Syria's oil and gas sector is made, especially since the country has excellent geological conditions, which could enable sizeable oil and gas production.

Lebanon

According to IRENA (8), Lebanon relies largely on imports to satisfy its energy demand. In terms of primary energy, consumption is met using the following six major components: (a) liquid petroleum gas (LPG), (b) gasoline, (c) gas oil, (d) kerosene, (e) fuel oil and (f) bitumen. The only energy produced domestically include solar water heating, hydro power and a minor solar PV.

In 2010, energy imports acco unted for approximately 96.8% of primary supply, and only 3.2% was locally produced from hydroelectric power plants and SWHs. The share of primary energy imports did not change significantly between 2010 and 2015, as political instability in the region prevented uninterrupted imports of natural gas, thus forcing various plants to rely on fuel oil. Primary energy production in Lebanon comes from mainly imported oil products. In 2016, fuel imports accounted for around 95% of overall energy production and imports. Some 96% of the country's total primary energy supply (TPES), which stood at 8.6 Mtoe in 2018, was sourced from primary and secondary oils, followed by coal at 2%, based on IEA's data.

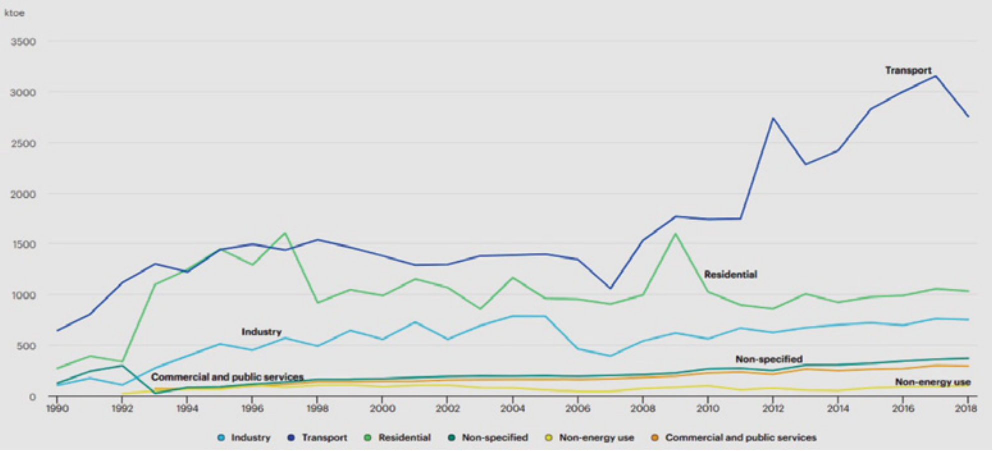
Figure 6.24 **TPES by Source in Lebanon, 1990-2018**



Source: IEA

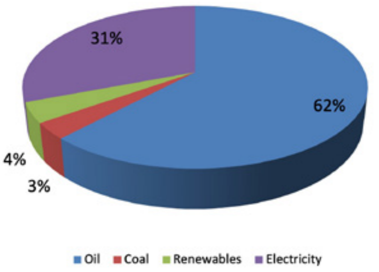
In 2018, the total final consumption (TFC) in Lebanon reached 5.3 Mtoe and was largely met by imported oil and electricity, with the highest share being consumed in the transport sector (52%), followed by the residential sector (19%) and industry (14%). The high dependence on imported oil products has increased the vulnerability of the Lebanese economy to oil price fluctuations. In addition, in recent years, Lebanon has experienced significant intermittency of electricity imports due to regional instability. As well as threatening the country's energy security, this has aggravated the electricity supply shortage. In this context, the country's high dependency on energy imports is a strong driver for the deployment of renewable energy sources, which will help improve Lebanon's energy security.

Figure 6.25 **Total Final Consumption by Sector in Lebanon, 1990-2018**



Source: IEA

Figure 6.26 **Total Final Consumption by Source in Lebanon, 2018**



Source: IEA

Figure 6.27 shows the evolution of oil products' imports in Lebanon between 2015 and 2018. The evolution of oil imports is consistent with each of the oil products keeping the same share of total imports. In 2019, total imports reached 8,618 ktoe, based on IRENA's data, representing a financial burden of around $6,248 million. Moreover, in 2019, an additional 350 ktoe of petroleum coke was imported, although this is not reflected in Figure 6.27, owing to incomplete information regarding its origin and use.

Egypt

According to African Energy Reports (9), Egypt has significant resource potential in each of oil, gas, wind, solar and hydro. In relation to gas, the 21.5 trillion cubic feet (tcf) Zohr field in the Mediterranean and latest gas agreements with Israel and Cyprus are indicative of ambitious plans to grow into a regional gas and oil hub.

Based on IEA's report (10), gas production in Egypt has undergone dramatic changes since the early 2000s. Domestic output grew by 17% per year on average between 2000 and 2008 (when production reached a peak of 62 bcm) and Egypt became a net exporter of gas. However, a significant reduction in investment resulted in a 40% drop in production between 2008 and 2015. The country became a net importer of gas again in 2015, chartering two FSRUs in order to be able to accommodate in LNG imports. The Egyptian economy is heavily dependent on gas: more than 80% of the country's power generation capacity is gas-fired. Declining domestic output therefore caused repeated power outages and weighed heavily on industrial competitiveness. LNG export facilities were idled, and more polluting oil products started to take market share.

The discovery of the aforementioned large Zohr offshore gas field in 2015, one of the biggest finds worldwide over the last decade, dramatically changed Egypt's energy outlook. With favourable upstream policies to expedite development, production from the Zohr field started in late 2017 and reached around 30 bcm in 2019. This growth is now being supplemented by production from several other fields, notably Nooros, Atoll and the first and second phases of the West Nile Delta complex, leading to a major turnaround in the country's production. Gas production in 2018 returned to the level of the previous peak in 2008 and Egypt achieved self-sufficiency later in the year.

With sustained upstream reforms and efforts to reduce arrears to international operators, gas production in Egypt is expected to grow to around 100 bcm by 2040, according to IEA's Stated Policies Scenario. The upbeat production outlook, coupled with the country's underutilised LNG export infrastructure, opens the possibility of Egypt going well beyond self-sufficiency and becoming a regional export hub, although this would require the resolution of a number of political and commercial issues. However, question marks remain as to Egypt's net export position in the longer term. On the

7 Lebanese Ministry of Energy and Water (MEW) (2019), "Update of the electricity reform paper".

supply side, there would be need for continued upstream investment as the outputs from the Zohr and adjacent fields reach a plateau[8]. But the bigger issue is that gas demand in Egypt may rise very rapidly due to demographic reasons and uncontrolled population growth. Egypt is already the largest gas consumer in Africa and there is strong potential for further growth, especially in the power sector where gas is the dominant fuel.

In addition, Egypt is a significant oil producer at around 670,000 barrels per day (b/d) in 2018, equal to 0.7% of global oil production. Much of Egypt's 400 million tonnes of proven reserves are concentrated in oil fields in the North-west (onshore) and the Red Sea (offshore). Currently, Egypt enjoys what is widely regarded as an electricity oversupply. Installed capacity stood at 55.9 GW in 2018, more than enough to meet a peak demand of 30.8 GW.

The expansion of renewables' share in Egypt's energy mix is high in the government's energy policy agenda. This is targeted to increase from 10% in 2019 to 42% in 2035. To achieve

Figure 6.28 **TPES by Source in Egypt, 1990-2018**

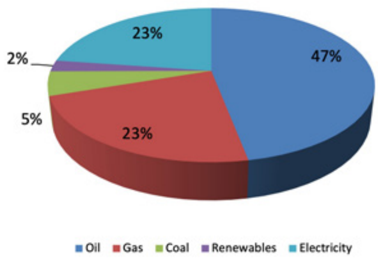
[8] Trade with other East Mediterranean countries (e.g. imports from Israel, exports to Jordan) can also impact the trade balance.

this, installed capacity would need to reach 93 GW, assuming that no new thermal generation is added, or existing such plants decommissioned. In 2018, Egypt's total primary energy supply (TPES) reached 95.6 Mtoe, with fossil fuels accounting for more than 95% of its primary energy production. As shown in Figure 6.30, oil and gas are, by far, the main primary sources of energy supplied and consumed in Egypt. Renewable energy (i.e. solar, wind, hydro, biofuels and waste) covered about 3.9% of the country's TPES in 2018.

Figure 6.30 **Total Final Consumption by Source in Egypt, 2018**



Source: IEA

In 2018, the total final consumption (TFC) in Egypt reached 61.4 Mtoe, with the highest share being consumed in the transport sector (29.3%), followed by the industry (28.6%) and the residential sector (22.8%).

7

The Legal Framework of the Energy Market in SE Europe

The Legal Framework of the Energy Market in SE Europe

Introduction

Safe and reliable delivery of energy has been the hallmark of energy policy and regulation in the industrialized world over the last century. More recently, regulators, policymakers and the industry began to focus their attention on ways to improve economic efficiency, increase productivity and reduce costs through a seemingly endless series of reforms. In some countries, utilities were encouraged to enhance transmission and interconnection facilities with neighbouring systems in order to pool energy resources. More recently, utilities have been encouraged to participate in regional organisations to buy and sell power, and to administer transmission, dispatch and scheduling of a variety of energy products. Certain countries have encouraged utility efficiency through a variety of performance-based incentives.

Policymakers have tried to reduce the barriers to entry by requiring non-discriminatory treatment among transmission users and prohibiting affiliate abuse. Utilities were encouraged to unbundle certain utility services; in some cases, regulators required the divestiture of generation or transmission facilities. Utilities have even been encouraged to provide retail wheeling services to facilitate competition for delivery service customers.

Consequently, many markets have developed competitive bid-based electricity auctions to set energy and capacity prices, which often take into consideration the cost of transmission congestion. These markets tend to be administered by independent or governmental entities that do not have a market position bias. Clearing prices set in these markets are intended to send price signals to maximise short-term efficiency (scheduling, dispatching and selling energy), as well as long-term efficiency (building new or retiring old generation and transmission facilities).

In certain countries, lawmakers and policymakers have encouraged developers to build and finance new renewable resources and to develop more effective means of conserving energy, through a variety of 'carrots' and 'sticks'. These measures have included subsidies such as feed-in tariffs and renewable energy credits, as well as utility requirements through renewable portfolio standards. In certain competitive markets, conserving electricity has been converted into a demand-side product with near or equal value to supply-side generation. New "smart grid" technologies have been created to increase the efficiency of transmission, generation, distribution and individual consumers' energy use.

Now, however, the myriad of efficiency mechanisms face new and unprecedented challenges. Transmission and distribution systems are ageing and desperately need upgrading. Severe new environmental requirements are leading to mass retirements of baseload coal-generation resources. Fuel prices are volatile, adding long-term uncertainty to energy prices. Spikes in the price of raw materials are making the development of new infrastructure all the more expensive. Cyber-security threats are exposing the vulnerabilities of our energy networks. And the global economy continues to threaten our ability to obtain the necessary credit to build and finance energy infrastructure.

In such a complex and uncertain environment, it is important both for the investor cum market participant, and the consumer to know the rules of the game and how likely these are to change and for what reason. Hence, the need of comprehensive and reliable information on the legal and regulatory framework in force.

Therefore, the aim of this Chapter is to highlight the major aspects of the SE European energy sector from the perspective of legal and regulatory framework over the past few years on a country-by-country basis.

The Chapter is not meant to be a treatise on any particular country's energy legislation and is not exhaustive to the point of eliminating the need of professional advice, but its main purpose is to raise readers' attention as to the energy legislation of each country in SE Europe, as defined by IENE, and assist in identifying the issues that might have a significant impact on investment and business development decisions. Undoubtedly, there are text repetitions as several energy developments touching upon legal and regulatory framework in the SE European region are also covered in other Chapters of the present study (especially in the Country Profiles), while a number of latest regional legal and regulatory energy issues are not included as this Chapter was lately updated in the first half of 2020. A special section has been added at the end of each country's legal framework account to discuss the impact of Covid-19 on investment and support initiatives. As all governments introduced various measures to support businesses affected by government restrictions imposed in response to the Covid-19 pandemic, there have been several side effects impacting each country's finances but also affecting the operation of government and the investment prospects.

7.1 ALBANIA

7.1.1 Introduction to the energy market

In Albania the energy sector is one of the strategic sectors and a priority of the Government of Albanian (GoA) given the diversity of energy resources (water, wind, solar, oil, gas, etc.) that the country possesses, which so far are not fully exploited. Albania has both thermal and hydropower to generate electricity, with the latter being more significant and having a greater potential for development. Liberalization of the energy market continues to be among the reform priorities of the GoA, along with the diversification of the energy sources and reducing energy dependence from imports. In the energy sector, the progress made to reduce distribution losses and by improving bill collection rate, despite the promising results, needs further consolidation. The reform for diversifying energy sources is crucial for having sustainable and growth-promoting public finances.

7.1.2 Electricity

Market overview

The introduction of the new Power Sector Law[1], a Third Energy Package Compliant Law was proclaimed as a major step forward, providing the legal ground for the establishment of a liberalised energy market. However, for the third year in a row, the country focus remained on the implementation of the Third Energy Package and its major tasks such as unbundling and certification of transmission system operators, unbundling of distribution system operators and full market opening. This required further concrete reforms with respect to market rules, e.g. related to balancing, day-ahead markets, market coupling, etc.

In 2016 the Government of Albania approved the new Albanian Market Model ("**AMM**") developed in accordance with the EU Directives on Electricity and also adopting the requirements of the Energy Community Treaty. The AMM outlines the main responsibilities and relationships among the market participants and Energy Regulatory Entity ("**ERE**"). In simple terms, the AMM is characterised by bilateral contracts for electricity between and among market participants. Ancillary services for Transmission System are purchased by the Transmission System Operator ("**TSO**").

Also in 2017 the ERE approved the Albanian Energy Market Rules ("**Market Rules**") which define:

(a) a set of rules that establish the procedures for market operations and management;
(b) a coherent framework under which participants in the electricity market can interact with each other;
(c) sale and purchase of electricity at freely negotiated prices; and
(d) conditions for participating as part of the Balancing Electricity Market.

[1] Law No. 43/2015, dated 30.4.2015 "On power sector", as amended.

These Market Rules promote an effective generation and supply of electricity and also the competition in sale and purchase of electricity.

To complete legal unbundling, which has starts since 2008, the state-owned power distributor OSHEE established three independent subsidiaries for distribution system operation, provision of universal service and supply of consumers on the market. Their assets, however, remain with OSHEE, which challenges their independence and leaves the formally unbundled service providers without operational capacity.

Balance responsibility is implemented by "transitional" balancing rules and the National Power Corporation KESH is still the sole service provider. In the absence of a local market price, the imbalances are settled using reference hourly prices from the Hungarian day-ahead market. Liquidity of the balancing market could be provided by services across the border, however, cross-border balancing between TSO and neighbouring transmission system operators is not in place yet. The amendments to the Power Sector Law of March 2018 have put in place the missing legal framework for the future organized day-ahead and intraday markets and set the timing of the Government's decision on establishment of the Albanian power exchange APEX to be taken by September 2018. The day-ahead and intraday market rules were developed and approved by ERE but their application is postponed until the corresponding functions are set. The momentum needs to be regained in order to accomplish the establishment of the independent market operator in 2019.

Regulatory overview

The Power Sector Law and the AMM define the participants in the energy market which include several operators and the ERE. Although presently, the contracts and tariffs between the various market participants are regulated at their inception in the energy market, under the new Power Sector Law the applicable tariffs shall be determined by free negotiations between parties to the contract. Thus, no other recent regulated electricity market activities have been observed.

The regulated market is presently organised and regulated through the following contracts between:

(a) KESH Gen and Wholesale Public Supplier ("**WPS**") (primarily for transparency of sale prices charged);
(b) WPS and Retail Public Supplier ("**RPS**");
(c) Transmission System Operator ("**TSO**") and other market participants for transmission-related services, including ancillary services;
(d) Distribution System Operator ("**DSO**") and other market participants for distribution-related services;
(e) Small Power Producers ("**SPPs**") and the WPS;
(f) RPS and its tariff customers;
(g) KESH Gen and Traders, including import contracts for the exchanges of power, which are subject to ERE scrutiny or procurement rules;
(h) OST and KESH Gen, SPPs, Independent Power Producers ("**IPPs"**) and Traders for the transmission losses and Ancillary Services.

The ERE retains the right to adopt standard agreements or procurement rules that are obligatory to be executed by Eligible Suppliers ("ESs"), IPPs, SPPs and other market participants when carrying out a bilateral contract with the WPS. Pursuant to the provisions of the AMM, some contracts between market participants are not regulated; thus, they are freely negotiable between the parties and these include:

(a) contracts between ESs and Eligible Customers ("**EC**");
(b) contracts between SPPs, IPPs, ECs and Traders;
(c) contracts between KESH Gen (i.e. the generating arm of the WPS and ESs or Traders, to the extent permitted under the present or other restrictions on WPS sales; and
(d) contracts between DSO and Traders, ESs, SPPs and IPPs for the necessary energy required to cover losses in the distribution system.

Trading and supply of electricity

The present AMM is a vertically integrated market model characterised by bilateral contracts for electricity between and among market participants. The AMM has directed that Wholesale and Retail Supply be public activities. Thus, after the unbundling of KESH, three different entities now fulfil the activity of the wholesale production, supply and retail supply of electricity.

KESH Gen retains the licence for the generation of electricity and is entitled to sell electricity produced to the WPS at prices approved by the ERE. In all cases, the ERE is entitled to monitor the process of the exchange and sale of electricity, in order to ensure compliance with the rules and procedures of sale and exchange of electricity, as approved by the ERE.

The WPS, being a separate entity in possession of a licence for the wholesale supply of electricity is entitled to purchase from KESH Gen all the electricity produced by KESH Gen from its hydropower plant and other generation plants, as well as from IPPs, SPPs, ESs and Traders to fulfil its obligations to the Retail Public Supplier ("**RPS**"), i.e. to service all the Tariff Customers.

The AMM also comprises: the RPS - an entity licensed for the retail supply to tariff customers at regulated prices determined by the ERE; IPPs - entities producing electricity that are not connected with the grid; Grid System Operators which maintain, operate and upgrade the grid in high, medium and low voltage levels and SPPs which are entities licensed to produce electricity by hydro, wind or other sources which qualify for feed-in tariff if their installed capacity fulfils the legal requirements (for hydro sources - up to 15 MW); and lastly, Traders and Tariff Costumers conclude the list of participants of the AMM. Pursuant to the provisions of the AMM some contracts amongst market participants are not regulated and so are freely negotiable.

Under the AMM, Traders are licensed entities which buy and sell electricity with the exception of sales to the RPS and end-user customers. Traders should be established as legal entities and the scope of their activity should be the wholesale buying and selling of electricity. Traders can buy electricity from KESH Gen (i.e. surpluses), IPPs and SPPs to then sell on to QSs, WPS, or a DSO (covering the distribution losses). When IPPs or SPPs sell directly to the WPS or other ESs, they require only a production licence and not a trading licence.

IPPs, SPPs and ESs may also be Traders, engaged in wholesale transactions, on the condition they obtain the necessary trading licence. The ERE shall ensure that the licences and licensing procedures for ESs and Traders are transparent and non-discriminatory and do not create an undue burden on the entry of Traders into the Albanian market, subject to any reciprocity agreement.

The Market Rules recently were amended by the ERE to reflect the obligation of all market participants to balance the electricity system under the Power Sector Law as of 1 January 2016.

Transmission and grid access

Transmission is regulated by the Transmission System Code - a document describing the relations between TSO and users and establishes procedures for the operation and development of the Transmission System according to the development of the Albanian and Regional Electricity Market.

The Power Sector law provides the unbundling of the transmission system operator and the distribution system operator as well as certain provisions regarding the certification process by ERE.

7.1.3 Renewable energy

Market overview

Albania is almost entirely depending on hydro power as hydropower resources now account for almost 98% of the country's energy production. Hydropower production fluctuates and is not equal throughout the year and, especially during 2017, has resulted in high energy imports, both in quantity and in prices due to dryness periods. This disbalance underestimated the great potential that Albania has in developing other sources of renewables, such as solar or wind sources of energy.

In February 2017, the Parliament approved the new law on promotion of the use of energy from renewable sources (the "**2017 RES Law**")[2], which is partially aligned with the EU RES Directive No. 2009/28/EC, as part of the *Acquis* – an obligation Albania has as a potential candidate for accession to Europe. The adoption of the 2017 RES Law has promoted and encouraged other sources of energy to start with pre-sale electricity contracts for generating works that are not subject to concession, thus proving for a diversified renewable energy resource policy. This is also due to the advancement on electricity production from renewable sources by technologies other than the one dominating domestic electricity production actually, with hydro resources only, as well as the rapid reduction of electricity generation costs from solar energy (PV) and wind (Aeolian), are globally the main sources of energy capacity increase in the wholesale market.

The Power Sector Law provides renewable energy producers with priority and guaranteed access to the electricity networks and also priority dispatch of electricity produced from renewable sources. All market participants including renewable energy producers are required to take balance responsibility.

Albania has taken a number of steps to include in its energy policy the requirements of the EU Directives for the establishment and development of the internal energy market and the promotion of production and consumption of energy from renewable energy sources.

Under the existing legal framework, the ERE is tasked with approving the necessary procedures and documentation for the connection of generation facilities to the grids. The alignment of the existing procedures for connecting renewable producers to the transmission and distribution networks as well as methodologies for establishing the cost of connection, in order to comply with the requirements of the Power Sector Law have not been yet completed. The ERE has adopted simplified procedures for the licensing of renewable energy producers which are connected to the distribution grids.

At present renewable energy makes up around 40 per cent of Albania's energy supply. This is largely due to the fact that virtually all electricity production is generated from hydropower. Many concessions and licences have been granted over the years to private companies for the construction and operation of small hydro-power plants although only a small percentage have been constructed to date (many still requiring financing). Diversification of energy sources through the promotion of production and consumption of energy from renewable sources remains one of the major reforms in this sector.

Other renewable sources are being explored, several licences have been issued for the construction and operation of wind farms. Given the beneficial conditions of the Mediterranean climate, solar power and photovoltaic energy generation are viable options, in addition to biomass and waste to energy sources for which some licences have been granted to date.

[2] Law No. 7/2017 of 2 February 2017 "On promotion of the use of energy from renewable sources", The Law 2017 RES Law is partially aligned with the Directive 2009/28/EC of the European Parliament and of the Council of 23 April 2009 on the promotion of the use of energy from renewable sources and amending and subsequently repealing Directives 2001/77/EC and 2003/30/EC.

Based on the Article 5 of the Law No 7/2017 of 2.02.2017 "On promotion of the use of energy from renewable sources", the National Renewable Energy Action Plan 2018 – 2020 ("**NREAP**") was approved, which sets out the roadmap for achieving the national target for the share of energy produced from renewable sources, consumed in the Electricity Sector, transport and in the heating and cooling sector by 2020. Specifically, the NREAP foresees an increase of the consumed electricity generated from renewable sources, with at least 172 ktoe (2,044 GWh) by 2020. NREAP also foresees the expansion of installed electricity generators based on renewable sources to 798 MW. The NREAP takes into consideration the progress in the development of these technologies towards these targets and adjusts them accordingly to ensure the achievement of the national target of RES consumption (38%) in 2020.

Support schemes

The existing Power Sector Law and the wider legal framework provide for certain types of support mechanisms that are granted to investors exploiting renewable energy sources. These are summarised below:

(a) Custom Duties Exemptions: a specific law has been approved to promote the construction of installations using renewable energy sources and which grants exemptions from custom duties for the import of machinery and other equipment to be used in the construction of installations using renewable sources.

(b) Feed-in Tariffs: this is the most successful form of support scheme and although in the renewable energy law feed-in tariffs are to be applied to many renewable energy sources, currently the option is only available for new and existing small hydropower plants ("**SHPP**") (i.e. with installed capacity up to 15 MW). The feed-in tariff is set by the ERE annually and any SHPP producer can upon request benefit from a 15-year power purchase contract with the WPS using the feed-in tariff for the entire term; the new Power Sector does not provide any longer for this form of support scheme.

(c) Guarantee of Origin Certificates ("**GOC**"): GOC's are official certificates issued as evidence that the power generated is from renewable sources. This certificate is issued after the qualification of the plant as being a generator from renewable sources and must be acquired prior to receiving a Green Certificate. The certificate shall include the amount of power generated by renewable sources, the name of the power plant and its capacity. GOCs can be transferred together with the power in accordance with rules and procedures defined by ERE.

(d) Green Certificate ("**GC**"): GC's are official certificates proving that the power was generated through renewable sources or by a combined generating mode which can be transferred (i.e. traded), separately from the power it certifies. The GC certifies the owner and also the place of generation, date of generation and the generating plant. GCs can be transferred in accordance with the rules and procedures defined by ERE.

To date there is only one international agreement for the sale and purchase of GCs and GOCs: the Agreement between the Italian Ministry of Productive Activities, the Italian Ministry of Environment and Protection of Territory and the Albanian Ministry of Infrastructure and Energy. With this agreement, Albanian and Italian power generators are able to sell their respective GCs and sell power with GOC to buyers from the other country. The 2017 RES Law establishes a broad framework for the auction mechanism and Contract for Difference (CfD) in future renewable projects. Currently, the state support in support schemes of RES in energy market in Albania is intended to be restructured for renewable energy sources and aims to replace the existing scheme of the feed-in tariff with a system based on CfD.

[3] By operation of the Council of Ministers Decision No. 179 of 28 March 2018 "On the approval of the National Renewable Energy Action Plan (NREAP) 2018 – 2020".

The new Albanian market model (approved pursuant to law 43/2015 "On energy sector" as amended), provides for the trading of energy from renewable sources, to the advanced/ liberalized market aimed to be opened by means of establishment of the Albanian Power Exchange (intended to start from January 2019).

Auction process

The Albanian government has recently passed a resolution in July ("CMD 349/2018 on RES Support Schemes"), designating the means for promoting the use of energy generated from solar and wind power plants and which stipulates the procedures for electing the eligible projects to benefit from such means.

According to the 2017 RES Law, feed-in-premium tariffs for renewables with over 2 MW of installed capacity should be granted through a competitive auction process, on non-discriminatory, clear and transparent basis. Notably, the CfD will not apply to small RES facilities (i.e. projects with an installed capacity up to 2MW and 3MW in solar and wind energy respectively), as these projects are supported by separate measures.Specific rules on how the auction process will be organised are broadly introduced in the CMD 349/2018 on RES Supportive Measures. It therefore remains to be seen whether the supportive scheme will help to create a suitable investment environment for RES projects in Albania.

Contract for Difference (CfD)

Under the 2017 RES Law, the main promotional measure is a specific form of a feed-in tariff termed contract for difference. The CfD can be characterised as a sliding feed-in-premium system, meaning that renewable energy producers will sell the electricity in the market and receive the variable difference between the auction price and the electricity market price (reference price) as a support measure.

The CfD will have a duration of 15 years. Interestingly, if prices in the electricity market go up and are higher than the auction price, the RES producers will be obliged to pay such difference.

The legal criteria of RES generation established by the Albanian Energy Regulatory Entity (ERE) provides that only the generators that fulfils the legal conditions might be supported pursuant to a CfD. The renewable technologies that will be acceptable for support according to CfD scheme include the following: (i) biomass transformation, (ii) wind in terrestrial boundaries, (iii) solar photovoltaics, (iv) hydro energy, (v) energy from the waste through CHP, (vi) gas from landfills and (vii) gas from the waste urban water.

Other supporting measures

The CMD 349/2018 on RES Supportive Measures provides for further support measures, including:

- making available to the RES producer the immovable properties required for the project implementation;
- priority access to the transmission and distribution grids; and
- producers receiving a guarantee of origin for their produced electricity.

However, the RES producers will not receive support in the form of an assumption of imbalances responsibility, as they will be responsible for their own imbalances and will be required to conclude either a contract with the transmission system operator or to transfer the balancing responsibility to another responsible balancing party, thus becoming a member of a balancing group.

Applicability of supporting schemes in practice

The applicable target for RES share in gross final consumption of energy in Albania for year 2020 is 38 %. Given the great potential Albania has for the construction and operation of new solar or wind power plants, the new support scheme under the 2017 RES Law can be a valuable tool.

In practice, none of the schemes has been implemented, thus causing further delays in implementing the new legislation, mainly for the following reasons:

- Necessary secondary legislation for net metering schemes, access to and connection with grid as well as guaranties of

origins are not in place as yet (this and other documentation is to be drafted as part of an ongoing project financed by EBRD);
- No CfD model has been drafted;
- Market openness and establishment of Power Exchange is postponed to January 2019.

Finally, the actual implementation of the 2017 RES Law will highly depend on the real willingness of the Albanian government to promote RES.

Based on the Law No 7/2017 dated 02.02.2017 "On promotion of the use of energy from renewable sources", was approved by the Council of Ministers Decision No. 369 of 26.04.2017 "On the approval of the methodology to decide the purchase price for electricity generated by small renewable sources from sun and wind". The Decision of Council of Ministers provides the tool to calculate the true cost of solar and wind implementation in Albania. As stipulated by this CMD, ERE is obliged to approve the purchase price of electricity produced from small renewable sources of sun and wind, in accordance with this methodology and averaged costs. Based on this CMD, the ERE Board by means of the Decision No 120 of 27.07.2017 decided that the electricity purchase price to be paid to small renewable sources from sun and wind" for 2017 is 100 Euro/MWh for photovoltaic and 76 Euro/MWh for wind; Actually, ERE with the Decision of the Board of Commissioners No 19 of 19.01.2018 "On the annual purchase price to be paid to existing priority producers of electricity for the year 2018", has approved the initiation of procedures for the approval of new price for year 2018, to be paid to priority producers;

Based on the Law No 7/2017 dated 02.02.2017 "On promotion of the use of energy from renewable sources", was approved the Council of Ministers Decision No 349 of 12.06.2018 "On the approval of support measures for the promotion of the use of electricity from renewable sources of sun and wind, as well as procedures for selecting projects for their benefit". This Decision establishes support measures for the promotion of the use of electricity from renewable sources of sun and wind and procedures for selecting projects that benefit from these measures, according to Article 8(1) of Law No 7/2017 of 2.02.2017 "On promotion of the use of energy from renewable sources" and the objectives of the National Renewable Action Plan 2018 – 2020. Supportive measures to promote the use of electricity from renewable sources of sun and wind are provided through a competitive, open, transparent and non-discriminatory process that provides credibility to participants and guarantees the provision of these measures to Albania's Economic Reform Programme 2019-2021, 80 entities that provide the best conditions for as regards the price of energy, technology used and the way of building the plant.

Based on the Council of Ministers Decision No 349 of 12.06.2018 and the objectives of the National Renewable Action Plan 2018 – 2020, the Ministry of Infrastructure and Energy (MIE) opened the bidding procedure to select the developer of the project for the construction of a photovoltaic plant with an installed capacity of 50 MW, as part of the Support Measures, in the Akërni Area (close to Vlora) and the construction of additional capacity of 20 MW up to 50 MW, which will not be part of the Support Measures.

Activities planned 2019:

- Implementation of the National Action Plan for Renewable Energy Sources (2018-2020), and achieving the national target for the share of energy produced from renewable sources,

- The signature of the contract and the beginning of the implementation of the Project for the construction of a photovoltaic plant with an installed capacity of 50 MW, as part of the Support Measures, and the construction of additional capacity of 50 MW, which will not be part of the Support Measures, in the Akërni Area (close to Vlora).

- The preparation and the approval of secondary legislation based on the Law No 7/2017 of 2.02.2017 "On promotion of the use of energy from renewable sources"

7.1.4 Natural gas

Market overview

Albania does not have a developed gas market at present and such development is one of the priorities set out in the National Strategy of Energy. Albania has a very low level of gas consumption, particularly with over 90 per cent of its energy being produced from hydro-power. However, it is in a prime location to serve as a transit country and is not yet connected to the international gas networks though this shall change in the future. It is thus important for the country to expedite the process of implementation of the Gas Master Plan and thus the gasification of the country.

Regulatory overview

Law No. 102/2015, dated 23 September 2015 "On the gas market" ("**Gas Law**") transposing the Third Energy Package was adopted in October 2015. It sets out a deadline of 18 months for the adoption of secondary legislation. This deadline was introduced taking into account the current absence of gas infrastructure and a gas market in Albania. The development of secondary legislation with the support of the Energy Community Secretariat commenced in December 2015. The Gas Law defines two main roles:

(a) The Ministry responsible for the energy sector, i.e. MEI is the supreme institution responsible for: (i) developing policies and plans for sustainable development; (ii) guaranteeing the sustainable and safe development of new natural gas infrastructure; (iii) approving and updating the National Energy Strategy which is further adopted by the Council of Ministers; (iv) preventing and managing crisis situations; (v) approving technical and safety rules; (vi) collecting and processing all information and data on the national energy balance, including the gas market;

(b) The ERE is responsible for regulations of natural gas activities and also for monitoring the security of gas supply (except for natural gas exploration and production, which is regulated under Law No. 7746, dated 28 July 1993 "On hydrocarbons (exploration and production), as amended" ("**Hydrocarbon Law**").

With the enactment of the new Gas Law, the ERE has expanded its scope of regulation to cover gas and has begun the preparation of the regulatory framework for the Natural Gas Sector. To date it has amended its Rules of Practice and Procedures and with the assistance of international advisors and donors it has completed the Licensing Procedures for the Natural Gas Sector and is working towards completing the set of rules and regulations to ensure proper functioning of the sector. However, the new Gas Law has substantially improved to ensure full and proper transposition of the Third Energy Package and is to a large extent aligned with the gas acquis.

Regulated natural gas market activities

As noted above the natural gas market is largely regulated and supervised by the ERE. Under the Gas Law the following activities require a licence: (a) transmission; (b) distribution; (c) supply (retail sale); (d) trading (wholesale); (e) operation of natural gas storage facilities; (f) operation of LNG facilities. Each activity requires its own separate licence and the licensing procedures are regulated by the sub-legal acts approved by ERE[4].

The Gas Law requires all natural gas undertakings to have obtained a license from the ERE before commencing activities in the gas sector, except for the operation of direct pipelines. The detailed procedure is specified in the relevant licensing rules adopted by decision of the regulatory authority – ERE and nothing has changed since their adoption.

[4] Decision No. 9, dated 11 February 2011 of the Board of Commissioners of ERE "On natural gas sector rules and procedures on licensing, modification, partial/full transfer, revocation and renewal of licences".

Exploration and production

The exploration and production of natural gas are both activities separately regulated under the Hydrocarbon Law (see below under Section 5).

Transmission and access to the system

As provided for under the Gas Law, the criteria for ensuring that users receive equal treatment and freedom of access to the gas transmission/distribution network are defined by the ERE. The activity of natural gas transmission and distribution is of public interest and is performed respectively by the TSO and DSO.

Trading and supply

As provided for by the Gas Law, the ERE is authorised to regulate the procedures and principles for tariff-setting.

LNG and storage capacity

The diversification of energy sources, through the development of the gas sector, consists of: creating a complete legal and institutional framework for the sector; the undertaking of a number of regulatory initiatives and investment projects in the gas infrastructure and market, whose main objective is to ensure significant security of energy supply through integration of the Albanian natural gas network on the regional and European ones, and increased economic benefits for the population and the different sectors of the economy in the country.

7.1.5 Upstream and the oil market

Market overview

All natural resources in Albania (inland and offshore) are owned by the state which has the right to explore, develop, extract, exploit and utilise natural resources. Pursuant to the Law No. 7746, dated 28 July 1993 "On hydrocarbons" (exploration and production), as amended (the "Hydrocarbons Law"), the state acting through MIE is entitled to grant a petroleum agreement to a person [one type of which is a Production Sharing Agreement ("**PSA**")] the right to explore, develop and exploit hydrocarbons in a defined area as agreed in the relevant PSA. The Natural Agency for Natural Resources ("**AKBN**") was created back in 2006 to deal, *inter alia*, with hydrocarbon activities on behalf of the Albanian state. The AKBN is a specialised institution dealing with the negotiations of the PSA, the monitoring of petroleum activities and policy-making processes.

The governmental objective is to negotiate the terms of the PSA with the oil industry in a fair and balanced manner, by taking into consideration the typical risks associated with exploration and the state's legal entitlement to revenue as the owner of the natural resources. There are predetermined means to grant a free block for exploration, development and production activities, so it can be either granted by the initiative of the MIE launching a tender process or the MIE inviting other interested parties to express their interest to this particular block in case a request or the same block has been lodged with the ministry. The blocks/oilfields/reserves designated for exploration, development and production are set out by the MIE itself.

Albania stands among 51 countries adhering to the Extractive Industry Transparency Initiative ("**EITI**"), a global initiative which seeks to improve the governance of the extractive sector. As of April 2015, different public entities from local and central government levels as well as current contractors which have entered into PSAs, are obliged to report to the EITI, pursuant to the standards set forth from this later and secondary applicable legislation.

Regulatory overview

Petroleum operations are regulated under the Hydrocarbons Law which together with a few accompanying regulatory acts and the Decree No. 782, dated 22 February 1994 "On the fiscal system in the petroleum sector", as amended ("**Law on petroleum taxation**"), forms the legal framework for the exploration, development and exploitation of petroleum in Albania.

Any person wishing to carry out petroleum operations must firstly obtain either a Prospecting Permit or enter into a PSA with terms and conditions which will be negotiated with the AKBN. In the latter case there is no separate licence per se; all matters are regulated and encompassed in the relevant PSA.

Taxation on petroleum, regulated by Law on petroleum taxation is levied as flat tax on taxable profit. Under this law, taxable profit is equal to accumulated revenue less accumulated capital and operating expenses as specified in the terms of the Petroleum Agreement. Accordingly, profit tax is applied when cumulative revenue exceeds capital and operating expenses accumulated since the start of operations.

Foreign investors becoming part of a petroleum agreement may negotiate fiscal stability terms to prevent future changes in certain taxes, however such stability should be limited to a certain period of time, applicable upon the entry into force of the relevant PSA and should not be extended during the entire term of the said PSA.

The current PSAs applicable in Albania are based on a cost recovery contract model and the GoA share is determined from the split of profit oil pursuant to the relevant percentages specified in each PSA. The contractor is entitled to recover all costs and expenses under the abovementioned PSA model, out of the share of available petroleum (i.e. the cost oil, which is sometimes called "cost recovery petroleum, cost recovery crude oil or cost recovery gas", as applicable). Whereas the stock of petroleum outstanding after the recovery of the contract costs, which is considered as "profit oil", should be allocated between the contractor and the GoA in accordance with a scale/formula specified in each PSA. The Hydrocarbon Law does not set out a specific manner of calculating the share or parameters since such is subject to negotiations between the parties of the PSA. At the beginning of 2016, the MIE publicly announced changes in the cost recovery model aiming to obtain from the oil companies the profit tax since the start of the production phase. According to this new model, 90% of revenue will be allocated for cost recovery purpose, while 10% of revenue will be classified as net profit and taxed in accordance with petroleum profit tax law and regulation. The new cost recovery model described above and limitation in fiscal stability clauses were incorporated in the most recent PSAs granted since 2017.

In February 2017 the Albanian parliament approved the Law No. 8/2017, dated 2 February 2017 "On the status of workers in the petroleum and gas industry", which sets minimum financial and healthcare benefits for the workers in the petroleum and gas industry. Both current and former petroleum workers will benefit from this status. They will be entitled to a salary not less than 150% of the minimum salary in force, higher pension payments and will further benefit from paid leave, which is double the time of paid leave labour regulatory framework in Albania. In case of illness directly or indirectly caused by their work conditions, the GoA will cover the treatment costs through a special health fund. The workers are further entitled to a payment in case their employment is terminated due to sector / company restructurings. Petroleum agreements awarded after the enforcement of this new law shall request oil companies to establish and manage a professional pension fund with contributes amounting to no less than 10% of their employees' gross salaries.

Regulated oil market activities

With the exception of activities conducted pursuant to a prospecting permit, no person can engage in petroleum operations without being authorised by MIE in accordance with the agreed terms and conditions stipulated in a Petroleum Agreement/PSA. A prospecting permit authorises the holder to carry out inter alia, perform prospecting activities in the areas covered by the permit by means of aerial, geophysical, geochemical, paleontological, geological, topographical and seismic surveys and to study their interpretation; and file an application for a PSA, if petroleum is discovered.

The Hydrocarbon Law states that the permit shall be valid for a two-year term, shall be not exclusive, shall not authorise the drilling of exploration wells and shall not grant to the permit holder any priority right (over any other party/person) to enter into a Petroleum Agreement/PSA with MEI, except when expressly stated so in the Prospecting Permit.

The PSA is a contract entered into between the AKBN acting on behalf of the MIE and the contractor allowing for the exclusive rights for the contractor to undertake explorations within the contract area for a period of five years (subject to extension as noted below) and exclusive rights to exploit for a period of no more than 25 years. Other typical provisions in a PSA relate to:

(a) Contractor property rights and right to construct and operate required infrastructure subject to third party rights and access under the law;
(b) Contractor right to trade and export petroleum exploited under the terms of the PSA;
(c) Fiscal regime applicable to operations (and exemptions applicable under the law);
(d) Obligation to perform a minimum work program backed by a performance guarantee;
(e) Obligation to present an annual work program and budget;
(f) Preference given to local employment and supplies during petroleum operations, where these are competitive in terms of quality, availability and cost;
(g) Change of law indemnities measures;
Obligation of the Contractor to carry out the Petroleum operations in a safe and proper manner in accordance with the generally accepted international petroleum industry practice and by causing minimal damage as is reasonably practicable to the general environment including, *inter alia*, the surface air, seas, lakes, rivers, marine life, animal life, plant life, crops, other natural resources and property, and shall forthwith repair any damage caused to the extent reparable, and shall pay reasonable compensation for all damage which is beyond repair.

Under the PSA the Contractor is authorised to conduct petroleum operations during an initial exploration period which can be extended twice. It is preferred that the exploration period includes a drilling commitment by the contractor. The phases of the Exploration Period are subject to negotiation. In the event that the Contractor declares a commercial discovery during the exploration period, it has the right then to proceed and extend for a development/production period of 25 years, which can also be extended. During the exploration period, the Contractor is subject to minimum work programs and expenditure obligations.

Exploration expenditures and capital expenditures are recoverable only in the case of a commercial discovery but not before the start-up of production. Operating expenditures are recoverable during the year in which they are incurred. Reasonable and necessary administrative expenditures of the Contractor are also recoverable. The Contractor is subject to tax on profit at a rate of 50 per cent of the realised profit and the royalty at typically 10 per cent of sales revenues.

One of the main priorities of the government is to reform the oil sector by restructuring and privatising the national state-owned company Albpetrol. The changes will confirm that the petroleum agreement ("**Albpetrol Agreement**") entered into on 26 July 1993 between Albpetrol and the Ministry at the time responsible for the energy sector, will be in force after Albpetrol's privatisation process. In addition, all rights over the management of free oil and gas blocks (blocks yet not operated by contractors), previously granted to Albpetrol, have been transferred from Albpetrol to MIE. The Ministry will have the sole discretion to negotiate with possible investors the petroleum agreement related to any free block and Albpetrol, once privatized, will only be responsible for blocks in which Albpetrol is currently conducting petroleum activities autonomously. After Albpetrol's privatisation, MIE and Albpetrol will enter into a new Petroleum Agreement, to determine the terms and conditions of Albpetrol's activities and to confirm the blocks in which Albpetrol will continue its activities.

Material provisions of the hydrocarbon's legislation and other licensing regulations

As of February 2017, the procedures for entering into a hydrocarbon agreement for the exploration, development and production of hydrocarbons are made through either the notice of the relevant MIE inviting the interested parties to participate through applications (so through the launch of a tender process); or invitation of other entities for submitting their applications, invited by the MIE, once they have already received a request for exploring/ developing a block /blocks or specified resource/s. Further, the MIE reasons of national security may refuse to enter into a new PSA or may refuse the approval of the assignment of shares of an existing hydrocarbon agreement.
The Petroleum law offers some incentives to foreign contractors, amongst which, the right to export their share of production derived from operations in Albania, unless there is an emergency call on the supply of crude oil in the local market.

As a matter of law, the conclusion of a PSA is exclusively based on the provisions of the Hydrocarbons Law and two 'umbrella' agreements (in case of reserves administered by Albpetrol). The first is Albpetrol Agreement, a special petroleum agreement concluded on 26 July 1993 between the Albanian state oil company (Albpetrol) and the MIE, acting on behalf of the Albanian state which is the sole owner of oil deposits. Under the Albpetrol Agreement, Albpetrol is entitled to carry out petroleum operations in certain oilfields and to do so also in cooperation with private companies under individual petroleum agreements (PSCs etc.). This is so, provided that Albpetrol has previously concluded for the specific oilfield, a so-called license agreement with MIE, duly represented by AKBN. Basically, by means of the license agreement, the Ministry (AKBN) entitles Albpetrol to conduct petroleum operations in the contract area and enter into PSAs with private contractors. The PSA between Albpetrol and the specific contractor makes them both part of the Licensee under a license agreement and jointly and severally liable to the Ministry (AKBN) pursuant to the license agreement. Albpetrol has no longer any pre-emption right over the free blocks. So, in case of an early termination of a PSA entered between MIE, Albpetrol and a contractor, Albpetrol will not have the exclusive right to continue any petroleum activity until the expiry date of the said PSA. The MIE will have the right to assign the free blocks to potential new contractors, according to the regulation on new petroleum agreements' approval procedure. As regards blocks administered directly by AKBN, only a single agreement, mostly in the form of a PSA is directly entered with the AKBN.

7.1.6 Forthcoming developments in the Albanian energy sector

The desired full and complete liberalisation of the energy sector is not quite accomplished yet and there are still fundamental reforms required and legal framework to be reinforced. The first step was made with the adoption of the new Power Sector Law which sets as a priority the development of a competitive energy market; the encouragement of a regional and European electricity trade and the improvement of investment conditions in the electricity sector. The subsidiary legislation is yet to be amended and aligned with the new Power Sector Law.

As part of the package of legislation in the energy sector, a new law on Energy Efficiency has been enacted, which has partially transposed the Directive 2012/27/EU and other amendments of this Law are currently under drafting process aiming the full transposition of the Energy Efficiency Directive.

The Gas Sector Law shall also be amended by fully bringing it in line with the Third Package of European Union Directives on the energy sector. In respect of the oil and gas sector, regulatory and policy developments are also underway as part of the overall state energy strategy. A new regulation and a draft law on the activity of exploration and production of hydrocarbons in Albania are expected to be approved by the GoA.

7.1.7 Impact of the coronavirus pandemic on energy and infrastructure[5]

A. Covid-19 Response Investment and Support Initiative – General

The Albanian Government and other public authorities have introduced various measures to support businesses affected by the government restrictions imposed in response to the Covid-19 pandemic in Albania. Below is a list of the key measures introduced until 10 April 2020:

(1) Financial subsidy to salaries of certain categories of employees and taxpayers (Council of Ministers' Decision no. 254, dated 27 March 2020);

(2) Sovereign guarantee to second-tier banks for loans covering salaries of employees of certain companies the activity of which has been shut down or impaired due to Covid-19 outbreak (Council of Ministers' Decision no. 277, dated 6 April 2020);

(3) Loan instalments deferral for borrowers suffering financial difficulties during the Covid-19 pandemic (Joint Order of the Prime Minister and the Governor of the Bank of Albania of 17 March 2020);

(4) Income tax filings and payment postponements for 2020 (Council of Ministers' Normative Act no. 10, dated 26 March 2020);

(5) Postponement of prepayment of simple profit tax instalments (Council of Ministers' Normative Act no. 11, dated 27 March 2020);

(6) Postponement of filing applications related to energy and gas licensing (Energy Regulatory Entity's Decision no. 51, dated 26 March 2020).

Except for the measures taken by the Energy Regulatory Entity (energy and gas sector), the initiatives have not been introduced on the basis of sectors, rather on the basis of business categories (self-employed, SMEs, larger businesses) adversely affected by governmental decisions.

The initiatives offer a variety of support including financial support, credit support, postponement of filings or tax prepayment deadlines, etc.

The financial subsidy to the salaries of certain categories of employees and taxpayers applies to:

(a) Employees of legal persons or sole entrepreneurs registered for CIT or as small businesses with an annual turnover not exceeding ALL 14 million during 2019. Employees shall be paid the minimum salary of ALL 26,000 per month. Double employed individuals may benefit only one payment.

(b) Self-employed individuals with an annual turnover not exceeding ALL 14 million and their family members working against no payment for them are entitled to benefit the minimum salary of ALL 26,000 per each person.

The sovereign guarantee to second-tier banks for loans related to salaries of employees of certain merchants and companies applies to companies larger than those covered by the first initiative, though the qualifying criteria remain to some extent unclear. The loan instalments deferral applies to borrowers having encountered financial difficulties during the situation caused by the Covid-19 pandemic and as such being unable to serve their loans. However, no further eligibility criteria have been set out and the credit institutions are granted discretion for assessing applications.

Income tax filings and payment postponements apply to certain businesses subject to income tax. Specifically, a four-month postponement is made available for

[5] The South East Europe Energy Handbook Special Edition "Overview of the Coronavirus Support Initiative & Impact on the Energy and Infrastructure Sectors in Southeast Europe", https://seelegal.org/see-legal-joint-publications/see-special-energy-handbook/

the filing of financial statements and related documentation of all categories of businesses namely by 31 July 2020, instead of 31 March 2020. For taxpayers with a yearly turnover of up to ALL 14 million, the payment date of the income tax calculated on the basis of the yearly statement is postponed to the second half of 2020. For the same category of taxpayers, the payment of income tax instalments for the first and second quarter of 2020 is postponed until 31 December 2020. Payment deadlines for taxpayers with a yearly turnover exceeding ALL 14 million together with a deadline for the submission of yearly personal income statements remain unchanged. Postponement of prepayment of simple profit tax instalments applies to businesses subject to simple profit tax. Postponement of filing applications related to energy and gas licensing (new licence, renewal, compliance, etc.) applies to companies operating in the energy and gas sectors.

Access

(1) With respect to the financial subsidy to the salaries of certain categories of employees and taxpayers, application should be made in the Albanian governmental electronic portal www.e-albania.al.

(2) With respect to the sovereign guarantee to second-tier banks for salary loans, application should be made following a cover agreement to be concluded between the Albanian Government and the various second-tier banks identified in the same Decision.

(3) With respect to the loan instalments deferral, beneficiaries should address a reasoned request to their credit institutions in order to benefit the right of postponement of the term.

(4) With respect to income tax filings, application should be made through the tax authority website.

(5) With respect to postponement of prepayment of simple profit tax instalments, application should be made through the tax authority website.

(6) With respect to postponement of filing applications related to energy and gas licensing, application should be made through the Energy Regulatory Entity.

Ease/speed of access

(1) With respect to the financial subsidy to the salaries of certain categories of employees and taxpayers, upon application, the tax authorities will verify the data within the first 10 days of the following month.

(2) With respect to the sovereign guarantee to second-tier banks for salary loans, credit institutions should process the requests of beneficiaries within three days upon receipt of the request.

(3) No details are provided in relation to the loan instalments deferral.

Period of support

(1) The financial subsidy to the salaries of certain categories of employees and taxpayers shall be effective as of 1 April 2020 and last no longer than three months.

(2) The sovereign guarantee to second-tier banks for salary loans shall be available to companies for a period of no longer than 30 days from the conclusion of a cover agreement between the Albanian Government and the various second-tier banks identified in the same Decision.

(3) Loan instalments deferral shall be made until 31 May 2020.

(4) Filing of financial statements and related documentation on all categories of businesses is postponed by four months i.e. by 31 July 2020 instead of 31 March 2020. For taxpayers with a yearly turnover of up to ALL 14 million, payment date of income tax calculated on the basis of a yearly statement is postponed to the second half of 2020. For the same category of taxpayers, the payment of income tax instalments for the first and second quarter of 2020 is postponed until 31 December 2020.

(5) Postponement of prepayment of simple profit tax is offered until October 2020 for prepayments due in the first and second quarter of 2020 and until December 2020

for the prepayments due in the third and fourth quarter of 2020.

(6) Filing applications for energy and gas licenses are postponed by one month after the end of the pandemic.

The initiatives taken have not addressed the interaction with existing insurance covers. Some useful links include: www.qbz.gov.al (Official Gazette Website, Albanian only) https://shendetesia.gov.al/masat-e-reja-per-te-parandaluar-perhapjen-e-covid-19/ (Ministry of Health and Social Protection Website, Albanian only)

B. Impact on the Energy and Infrastructure Sectors

The energy sector is not covered by the Order of Minister of Health and Social Protection no. 193, dated 20 March 2020 which specifies the sectors/industries whose activities are shut down for the duration of the Covid-19 pandemic. Thus, legally the sector is not affected by any prohibition of activity order. However, the movement restrictions imposed by the Government (including the prohibition of public transportation, time limitations of free movement of people, etc.) have impaired the normal functioning of such businesses.
For the supportive measures, see above.
Furthermore, the Ministry of Infrastructure and Energy has postponed bidding deadlines for certain projects.

The infrastructure sector is not covered by the relevant Order of Minister of Health and Social Protection no. 193, dated 20 March 2020. Yet, the Public Procurement Agency has notified all public authorities asking to suspend for a specified term (initially two weeks) all contracts except for those that "are indispensable". This notification, while legally questionable, has also created confusion among the respective companies. Moreover, the movement restrictions imposed by the Government (including the prohibition of public transportation, time limitations of free movement of people, etc.) have impaired the normal functioning of such businesses.
Furthermore, the Ministry of Infrastructure and Energy has postponed bidding deadlines for certain projects.

As a general note, the measures taken by the Albanian Government relating to the limitation of free movement and the support of individuals/businesses have raised legal questions about their lawfulness (particularly constitutionality). Most importantly, the Government declared the State of Natural Disaster only on 24 March 2020 (Council of Ministers' Decision no. 243), which could have been a plausible legal basis justifying all restrictive measures taken by the Government earlier, i.e. as of 11 March 2020.

Apart from this, such measures, including the supporting ones, remain to a considerable extent unclear (especially in relation to eligibility criteria, etc.), therefore leaving room to public authorities for considerable discretion in implementing them. This, in turn, seems to have already affected negatively businesses.

7.2 BULGARIA

7.2.1 Introduction to the energy market

The Bulgarian energy sector has undergone serious transformation in the last decades and continues to attract foreign investments in Bulgaria. Bulgaria is one of the few countries in the region with nuclear power facilities and due to its geo-economic location, it is a focal point for a number of strategic energy infrastructure projects.

The sector is mostly privatised, and the market is fully liberalised (particularly in the electricity sector). The Bulgarian state still holds substantial energy assets by way of a holding company named "Bulgarian Energy Holding" ("**BEH**"). BEH controls some large electricity generation capacities (including the largest lignite coal power plant and the only large pumped-storage hydroelectric power plant), the electricity transmission system, and the natural gas transmission, storage and supply.
In June 2011 the Bulgarian Parliament adopted the Energy Strategy of the country until 2020,

which acknowledges the challenges and sets out five priorities for the sector aiming to ensure energy needs and protect consumer interests: guaranteeing the security of supplies; boosting energy from renewable sources; improvement of energy efficiency; development of a competitive energy market.

7.2.2 Electricity

Market overview

After the implementation of the so called Third Energy Package[6], the liberalization of the market has been a major trend and source of controversies in the last years. Practically all customers other than household and small business or public consumers connected to low voltage networks were forced out of the regulated market. On the generation side, in the context of the commitments of BEH approved by the European Commission under the case opened against BEH for alleged abuse of dominant market position in the wholesale electricity market in Bulgaria, the generation subsidiaries of BEH were compelled to offer part of their electricity at the newly opened local electricity exchange ("**IBEX**"). By way of reforming the scheme for promotion of electricity generation from renewable sources most of local renewable generation facilities were also compelled to sell their electricity at the electricity exchange. The development of the open market and the electricity exchange as its backbone have not gone as smoothly as planned with major local industrial consumers complaining of lack of transparency and predictability at the market and alleged market manipulation involving state-owned generation companies as a result of which major price spikes were recorded at the IBEX in the second half of 2018 and continuing in 2019. The insolvency of certain major electricity traders also caused turbulences in the market. The only sector which has remained 100 per cent owned by the State is the national transmission grid and the supplies of electricity for the regulated market through the transmission grid. Currently, the national transmission network is owned by ESO after the unbundling of transmission assets from the assets of the National Electricity Company EAD ("**NEC**") which now remains responsible for national supplies in the regulated market and owns a number of generation capacities. Both companies are owned by the Bulgarian Energy Holding EAD which is also the owner of some project pipeline, mining and heat production companies and the nuclear power station Kozloduy. ESO deals with the operational regime planning and control of the electrical power system in Bulgaria, the synchronisation of the Bulgarian electrical power system operation with the electrical power systems of the European countries member of the Union for the Coordination of Transmission of Electricity ("**UCTE**") and coordination of joint operation with other electrical power systems.

The distribution and end-supply networks were privatised and are beyond the control of the State, albeit under a licence regime only. The production of electricity is currently performed by both state and privately owned companies with the Bulgarian state still controlling the vast majority of the (most cost effective) generation through the Kozloduy NPP, the largest lignite power plant Maritsa East 2 and the largest hydro power plants owned by the National Electricity Company EAD ("NEC"). The indicative goals for the energy mix up to 2020 correspond with the EU goals for broadening the share of renewable energy and reduction of CO_2 emissions.

The regulatory framework has been constantly changing in recent years. A set of amendments to the Energy Act were introduced in 2012/2013 aiming further liberalization of the energy market. These implement in detail Directive 2009/72/EC of the European Parliament and of the Council of 13 July 2009 and the Third Energy Package principles in general in the following manner:

[6] The package consists of two Directives, one concerning common rules for the internal market in gas (2009/73/EC), one concerning common rules for the internal market in electricity 2009/72/EC) and three Regulations, one on conditions for access to the natural gas transmission networks ((EC) No 715/2009), one on conditions for access to the network for cross-border exchange of electricity ((EC) No 714/2009) and one on the establishment of the Agency for the Cooperation of Energy Regulators ACER ((EC) No 713/2009). They were adopted in July 2009.

- division of transmission from production and sale of electricity and introduction of guarantees for independence of the grid operators;
- guarantees for the development of the grid;
- introduction of new powers to the Energy and Water Regulatory Commission;
- clear definition of consumer rights;
- exclusion of the users of high and middle voltage electricity from the regulated market and the introduction of the last instance suppliers;
- setting up of the Independent Bulgarian Energy Exchange which started operations in January 2016.

Significant changes to the Energy Act and the Energy from Renewable Sources Act were also introduced in 2018 and again in May 2019 by way of which the framework for promotion of the generation of electricity from renewable sources and highly efficient co-generation was materially amended and such generation facilities (with exception of those with installed capacity of less than 1 MW) were compelled to sell their electricity at the IBEX.

Regulatory overview

The regulation of the electricity sector has several layers.

The first layer is the core energy regulatory framework covering, among other things, the regulation of electricity generation activities, encouragement of production of electricity from renewable sources, relations between the investor and the distribution/ transmission companies, etc. These issues are regulated mainly by the Energy Act of 2003 (State Gazette No. 107 of 9 December 2003, as amended from time to time). Special rules applicable to renewable energy projects are set out under the Energy from Renewable Sources Act of 2011 ("**RES Act**") (State Gazette No. 35 of 3 May 2011), the Energy Efficiency Act of 2015 (State Gazette No. 35 of 15 May 2015). There are also a number of secondary level regulations issued by the Council of Ministers or competent Ministers (such as the Minister of Energy) regulating various aspects such as price regulation, security and safety requirements for electricity equipment, connection to the grid, etc. The local energy regulator – the Energy and Water Regulatory Commission also issues secondary level regulations such as Rules on Trading in Electricity, Rules for Access to Electricity Networks, etc.

The government bodies and institutions which are granted powers to monitor and regulate the electricity sector include:

(a) The Parliament – according to the Energy Act the Parliament of Bulgaria approves a Strategy for Sustainable Energy Development of Bulgaria;

(b) The Council of Ministers of Bulgaria – the Council drafts and implements the above Energy Strategy approved by the Parliament;

(c) The Minister of Energy (the "**Minister**");

(d) The Energy and Water Regulatory Commission (the "**Commission**" or the "**Regulator**") – this is the main regulatory body for the energy sector (as well as the water and sewage sector). Apart from its general powers, the Commission has been also granted investigatory and enforcement powers to control the enforcement of the prohibitions under Articles 3 and 5 and the obligations under Article 4 of Regulation (EU) No 1227/2011 of the European Parliament and of the Council of 25 October 2011 on wholesale energy market integrity and transparency;

(e) The Sustainable Energy Development Agency – this is a state authority responsible for the implementation of the State policy on encouragement of the production and consumption of electricity and heating power produced from renewables.;

(f) Electricity System Operator EAD – this is a company indirectly owned by the State.

Regulated electricity market activities

The Energy Act provides for licensing regimes in the electricity sector.Special rules were introduced in 2018 in respect of activities of operators of publicly accessible electricity charging points but those remain not subject to a licensing regime.

Subject to price regulation by the Regulator are the prices for the following activities:

(a) Connection, transmission through and access to the national transmission grid and the regional distribution networks;
(b) Sale of electricity by generation companies to the public supplier NEC within certain quotas which are determined by the Regulator for the purposes of meeting the demand of the regulated market;
(c) Generation from renewable energy sources (subsidies) in certain cases;
(d) Sale of electricity by the public supplier NEC to the end suppliers for sales at the regulated market which comprises business and household customers connected to the low voltage grid;
(e) Sale of electricity by end suppliers to their clients at the regulated market – households or business consumers which are connected to the low voltage grid;
(f) The prices for other services determined by the Regulator related to the core licensing activities of a licensee.

The prices for electricity at the balancing market as well as the prices for the electricity supplied by the last resort suppliers are not determined by the Regulator (thus not subject to regulation in the strict sense) but are determined by the licensee for the respective activity under rules and methodology approved by the Regulator.

Material licences for electricity generation

Regarding the Licensing Regulation (State Gazette No. 33 of April 2013) and the licensing procedures there are no recent remarkable changes in the Bulgarian market.

Under the Energy Act, any company which owns or intends to construct electricity generation facilities with an installed capacity of over 5 MW must obtain a generation licence from the Commission. The requirements for the persons applying for a licence are set forth in the Energy Act and the Ordinance for licensing of the activities in the energy field, State Gazette No. 33 of 5 April 2013 ("Licensing Regulation").

The licence may be issued with a term of validity between one and 35 years taking into account the service life of the generation assets and the financial status of the applicant. The term of the licence may be extended for a period not longer than the initial term, provided that the licensee meets the requirements of the Energy Act and duly performs all its obligations and complies with the requirements under the licence.

Generally, the preconditions for issuance of a licence under the Energy Act are the following:

(a) The applicant should be a legal entity registered in compliance with the Bulgarian Commerce Act or the legislation of any EU or EEA Member State. Such entity should not be insolvent or in liquidation;
(b) The applicant should have the technical and financial capabilities, material and human resources and organisational structure necessary for performance of the licensed activity;
(c) The energy facilities for carrying out the licensed activity should comply with environmental protection and safety operation requirements; and
(d) The applicant should have property rights over the energy facilities (if they are constructed). An application for a licence may also be filed before the facility is constructed.

The documents and information which need to be submitted with the application to evidence the applicant's compliance with the abovementioned requirements include: (i) business plan for up to 5 years; (ii) application for approval of prices (if the licensed activity involves regulated prices); (iii) information on the financing sources for the activity; (v) information on the applicant's or its controlling shareholders' experience in carrying out an activity similar to the licensed one; (vi) information on the applicant's management and organisational structure and the education and qualifications of the management personnel.

A licence preceding the construction of the energy production facility can be issued upon request of the applicant, provided that it can prove the necessary financial means to construct the facility. In this case the licence shall provide for the terms and conditions for construction of the facilities (i.e. wind turbines and the infrastructure thereof) and commencement of the licensed activity.

Upon completion of the facilities' construction, the licensee should request that the Commission issue a special permit for the facilities to enter into commercial operation. The above licences and permits are without prejudice to any other ancillary requirements which may be prescribed by the general legislation, such as building permits, health and safety approvals, environmental impact assessments, etc.

Trading and supply of electricity

(a) Trading
The market in electricity was liberalised in theory since 2007 but the practical liberalisation occurred at much slower pace and the free market consisted of only about 100 (mostly high voltage grid) consumers as of 2012.

The amendments introduced in the Energy Act in 2012, 2013 and 2015 for implementation of the Third Energy Liberalization Package directives and recently in 2018 and 2019 forced the market liberalization and the practical operation of the balancing market and the electricity exchange. As a result as of the end of 2017 there were more than 130,000 consumers active in the free market[7]. Raising wholesale prices at the IBEX during 2018 and major price spikes on numerous occasions however seem to undermine the confidence in the market of both customers and traders. Media reports note that numerous traders have exited the market in 2018 and according to the annual report of the local Regulator about 25,000 customers have left the open market and moved back to supplies at regulated prices (an option that is yet available for small business consumers connected to the low voltage grid).

In January 2016 the long expected exchange for electricity trading in Bulgaria started to operate. IBEX was originally incorporated as a state-owned company (a subsidiary of BEH) but in order to assure the independence of IBEX from the state-owned energy stakeholders in February 2018 the shares of IBEX were acquired by the Bulgarian Stock Exchange AD – the company that operates the only functioning regulated stock exchange market in Bulgaria.

In order to boost the IBEX market, new rules have been recently introduced pursuant to which all generation facilities with an installed capacity of 1 MW or more must sell their electricity at one of the market platforms of IBEX. Only generation companies which supply their own facilities or third parties customers via direct electricity lines as well as renewable energy generation facilities put into operation after 1 July 2019 are exempted from the above requirement and may sell electricity via bilateral agreements.

IBEX opened with a day-ahead market and added a centralized market for bilateral contracts at the end of 2016 and an intraday market in April 2018. According to information from IBEX as of June 2019 there were 71 active members operating on the day-ahead market, 64 – on the centralized market for bilateral contracts and 53 on the intraday market of the exchange. On the first two platforms, deals are concluded automatically and at clearing prices determined by the exchange systems and IBEX is itself a counterparty on all deals and carries the corresponding risks and responsibilities. On the third segment, bilateral deals are actually concluded, and the role of IBEX is as an intermediary between the trading participants, but IBEX is not a party to the deals. Deals may be concluded by way of automatic or manual counteroffers matching or by way of organizing of sale or purchase auctions by trading participants. The Commission in accordance with its powers has approved Rules for Trading

[7] Data provided by the Association of traders with electricity in Bulgaria.

in Electricity (State Gazette No. 66 of 26 July 2013, as amended and supplemented).

According to the Rules, the ESO administrates deals with electricity as well as organises the balancing of the market (the covering of the differences between scheduled deliveries and actual physical deliveries). For the purpose of the balancing of the market, hourly schedules have to be provided to ESO by the free market solo participants and the coordinators of balancing groups and they arrange the imbalances by selling to or purchasing electricity from ESO covering the positive or negative imbalances. Each year the Commission issues decision for determining quotas (quantities) of electricity to be produced by certain producers and sold to NEC as a public supplier at prices determined by the Commission (for the purposes of the supplies at the regulated market).

In May 2019 the access and transmission fees as well as the 5 % levy in favor of the ESF over exported electricity were finally abolished as a consequence of a judgment of the ECJ in Luxembourg of December 2018 prohibiting Member States from imposing a levy on the export of electricity produced on their territory. Bulgaria was the only country in the European Union that imposed such levies on the electricity produced on its territory which were viewed as de facto export fees in breach of EU laws and were a substantial hindrance to the plans for market coupling of the Bulgarian electricity exchange market with those of neighboring countries.

(b) Supply
In accordance with Directive 2009/72/EU the model of independent transmission operator was introduced and ESO has been licensed as such. In addition to the national high voltage network owned and operated by ESO, there are four distribution network operators in Bulgaria (owners and operators of mid and low voltage regional grids - **DSO**s) and four end-supply companies (form the same corporate groups as the DSOs) - licensed entities which supply electricity at regulated prices to household consumers and companies connected to the low voltage grid who have not chosen a supplier at the free market.

Only household customers and (small) non-household customers connected at the low voltage network can be supplied in the regulated market. Theoretically such customers may choose to be supplied at the open market as well but due to the more favourable and predictable conditions for supply at the regulated market, only a marginal number of them have so chosen. All other customers must choose a supplier at the open market.

The end suppliers in each distribution network as well as NEK act also as suppliers of last resort (**SLR**s) with the obligation to supply electricity to customers who are to be supplied at the open market but have not chosen an electricity trader or when the chosen electricity trader fails to supply for reasons non-attributable to the customer. The SLRs' final selling prices are determined by the SLRs in accordance with a methodology approved by the energy regulator. Any client has the right to choose a supplier (whether a local one or located in another EU country). The relevant grid operator performs the change of supplier pursuant to the Rules within three weeks as of receiving of a request in writing from the client.

All consumers connected to the high and middle voltage grid are outside the regulated market and have to choose their supplier in the free market. In order to secure electricity supply for those who have not made their choice of supplier / the supplier they have chosen is still not technically capable of supplying electricity in the respective region – the figure of the last resort supplier has been introduced wherein the Commission determines the prices of the electricity to be sold by the last resort supplier.

Transmission and grid access

Connection
The connection to the grid is regulated by the Energy Act and a special Ordinance No. 6 of 24 February 2014 (the "**Connection Ordinance**").

Connection to the grid shall be performed by either the ESO (the owner of the national transmission grid) or the respective company owner of the regional distribution network (depending on whether the generation capacity is below or above 5 MW).

According to the applicable rules, the procedure consists of three stages:

• Official statement on the terms and conditions for connection
Upon request by the respective applicant of connection the network owner must issue a statement on the terms and conditions under which it shall connect the generation facility to the network. The statement describes the technical requirements for the facilities of the project and the facilities which have to be constructed in order for the connection to be made. Connection may be refused only on objective technical reasons and the refusal is subject to appeal before the Commission.

• Preliminary connection agreement
As a next step the applicant must sign a preliminary agreement for connection to the network based on the terms described in the statement for connection.

• Final connection agreement
After the issuance of a Construction Permit for the respective facility applying for connection a final Connection Agreement is signed.

The connection fees payable to the gird owner are regulated by the Commission.
(a) Transmission and access to the grid agreement
Connection Agreement invites the company to sign it within 15 days of filing the Application. The term of the final connection agreement cannot exceed two years as of its execution and it is terminated upon commissioning of the project.
(b) Access to the Grid Agreement
Upon commissioning of the project an access to the grid agreement shall be concluded as a condition for the grid user to enter into power purchase agreement and be supplied with energy. The access to the grid agreement must be subject to general terms and conditions approved by the Commission. Consumer supplied at regulated prices are not obliged to sing access agreements but are supplied through the grid under general terms and conditions approved by the Commission. The agreement shall deal with the indemnification payable by the owner of the network to the company in the event of limitations of the evacuated electricity.

Fees are payable by grid users for the access to and transmission of electricity supplied to them through the grid are regulated by the Commission. Until 2019 only local customers and PV and wind generation companies were obliged to pay access fees but as of July 2019 such fees were also introduced for all local generation companies.

7.2.3 Renewable energy

Market overview

The sector for generation of electricity from renewable energy sources has gone through significant turbulences and has been subject to numerous changes of the applicable legal regime in the last ten years.

Originally in 2007 Bulgaria adopted a scheme for promotion of electricity generation from renewable sources (RES) based on feed-in-tariffs (mandatory off-take of all generated electricity at special preferential prices). In 2011 a new law was adopted – the Energy from Renewable Sources Act (the "RES Act") preserving the same concept but introducing certain specific requirements. The declared purpose of the law was to deal with the issues created by the previous legal framework and namely the booming development of new projects which in many cases were built in environmentally sensitive areas.

However, due to the late adoption of the new rules and the inadequate regulatory decisions taken, the new rules have not helped "cool down" the developments in the sector and more than 900 MW of RES generation capacity was connected to the grid in 2012 alone (mainly photovoltaic) at preferential prices high above local market process. This created significant pressure on consumer electricity prices and urged the government and the energy regulator to practically halt any future developments and to seek various means to restrict the operation of renewable capacities already connected.

Ultimately, by amendments to the Renewables Act as of 2015, all support schemes for new projects commissioned after January 2016 were suspended, except for the projects with an overall capacity of up to 30 kW constructed over roofs or facades of buildings connected to the distribution grid or the land adjacent to such buildings in urbanized territories.

The efforts to optimise the promotional regime continued in 2018 by restructuring completely the promotional regime for all existing RES projects as well (see below for details).

Support schemes

The RES Act provides for a system of encouragement of generation of electricity from renewables based on feed-in tariffs. The system comprises the following key elements:

(a) The owners of the national transmission grid and/or regional transmission systems are obliged to connect renewable energy generation facilities, subject to compliance with the special procedures under the Renewables Act. The interconnection costs associated with interconnection facilities up to the boundary of the electrical facilities are borne by the generation company. General costs associated with the expansion of the capacity of the grid are borne by the grid owner;
(b) The owners of the national transmission grid and/or regional transmission systems are obliged to provide guaranteed access to the grid and transmission as well as priority dispatching of electricity generated from renewable sources subject to relevant technical requirements for the security of the system;
(c) The national supplier (NEC) and the regional suppliers (end-suppliers) are obliged to purchase all electricity generated from renewable sources, which is certified with a generation (origin) certificate (see below). This obligation is to be reflected in long-term power purchase agreements signed with the respective purchaser; and
(d) Special preferential prices are set by the Commission at which electricity from renewable sources is purchased (see below).

Feed-in Tariff System

A system of promotion of generation of electricity from RES involving conceptually a feed-in-tariff (FiT) system and long-term power purchase agreements (PPAs) has been in place in Bulgaria since 2007 and until recently, even though the details of such system have been changed numerous times.

Originally the system envisaged an entitlement of RES producers to sell all electricity generated to a dedicated off-taker. The off-taker was the national supplier NEK (for facilities connected to the transmission grid)[8] or the relevant licensed regional end supplier (for facilities connected to the relevant distribution grid) . That entitlement was guaranteed under a long term power PPA with the relevant off-taker for periods depending on the category of RES used for generation (12 years for wind and 20 years for PV). The tariffs at which RES producers were entitled under the PPAs was determined by the Commission annually and the prices were different depending on the type of RES and the capacity of the generation facilities. The price applicable to a particular facility was the one determined by the Commission for the period when the respective facility was put into operation. Such price was then applied for the whole period of the relevant PPA.

The legal framework envisaged that the costs of the off-takers for the purchase of electricity from RES under the relevant PPAs at prices

[8] It is to be noted that there was a legal obligation of NEC to subsequently purchase all RES electricity from the other off-takers at the price at which they had purchased it from RES producers. Therefore, ultimately, the off-taker of all RES generated electricity was NEC.

significantly exceeding market prices must be covered ultimately by the end consumers. For that purpose, it was envisaged that the Commission must determine periodically certain fee or price (or a component of the electricity prices) per unit of electricity which must be paid by all end consumers of electricity based on their consumption.

Initially, all electricity generated by a RES facility was to be purchased at the special feed-in tariffs. In 2014 and 2015 the law was changed (including for projects already in operation) with the aim to reduce the quantities to be purchased. Under the new rules only the annual quantities of electricity which were used in the respective calculations for setting the original feed-in tariffs by the Commission are to be purchased at such preferential prices (the so called "net specific generation"). The rest of the electricity is to be purchased by the off-taker at much lower price or sold to the free market. The "net specific generation" was defined as "the average annual electric power generation by 1 kW of installed capacity in accordance with the Commission's decision fixing preferential prices after deduction of the producer's own needs".

In addition, in July 2015 the Energy Act was amended and a special Fund was established – the Electricity System Security Fund" (the "**ESF**"). The cash accumulated by the fund should be mainly used for covering of the expenses of NEC and the end suppliers incurred in relation to the off-take obligations for RES electricity as well as the similar obligations for highly efficient co-generation.

The source of the funds to be accumulated into the ESF are:

- a monthly levy in the amount of 5% payable by all producers of electricity (including RES producers) as well as all by electricity and gas transmission operators and gas storage facilities over their income from sales of electricity (including income from premiums for RES producers) / or respectively - fees for access, transmission or storage (VAT excluded);
- the so called "payments for covering obligations to the society" – i.e. the price or price component which all end consumers must pay to cover the costs of the promotional schemes, in the amounts determined by the EWRC;
- other sources, such as proceeds from sale of CO_2 allowances, etc.

Premiums System

Significant changes to the legal framework on promotion of RES generation were introduced in July 2018, with the aim to foster the energy market liberalization and integrate RES generation into the open market. The changes affect not only RES producers, but also have material effect on the relations between all market participants. The changes remove the "single-buyer model", i.e. NEK is no longer acting as the single off-taker for all RES electricity at preferential prices.

The changes originally affected only generation facilities with an installed capacity of 4 MW or higher but in May 2019 the application of the new regime was widened to cover generation facilities with an installed capacity of 1 MW or higher – the vast majority of local RES projects. For facilities with an installed capacity below 1 MW the original feed-in tariff system was preserved.

Under the new rules the system of purchase of electricity at preferential prices under long term PPAs of the affected producers is terminated. In replacement, the affected producers will be obliged to sell all their energy output at the local electricity exchange IBEX. For the purpose of covering the difference between the previously applicable preferential prices to which RES producers were entitled and the market prices at which they will have to sell their output under the new system, it is envisaged that producers will be entitled to receive "premiums" from the ESF under a contract with the same (the implemented scheme resembles the so called "contract for differences" known to other jurisdictions).

The amount of the premium to be paid by the ESF will be a fixed amount per MWh and it is determined annually by the Commission. For the purposes of determining the amount of the premium, the Commission determines a reference price (named "prognostic market price") for the next 12 months. The reference price is different for the different types of technology (wind, PV, hydro, co-generation, etc.). The Commission then determines the premium as the difference between the preferential price to which each of the RES producers was entitled under the previous feed-in tariff regime and the fixed reference price for the respective technology. The Commission is entitled (but not obliged) to update the reference price and thus the amount of premiums during the 12-month period, but not more often than once per 6 months, if there are significant differences between the actual market prices and the reference price.

Premiums are only payable for the above mentioned "net specific generation" of each facility (as it was for preferential prices under the previous regime) but not for all the energy output of the facility. As a precondition for the payment of the premium, the relevant RES producer must obtain from the Sustainable Energy Development Agency (**SEDA**) the so called "guarantees for origin" for the electricity subject to premium and transfer them to the ESF.

Under the above structure if a particular RES producer is able to sell all its output at the market and achieves market price higher than the reference price, it will receive gross income higher than the previously applicable feed-in tariffs. If, however it is unable to sell all its output, or the sale price achieved is lower than the reference price as established by the Commission, the RES producer will not be fully compensated for the difference between the reference price and the achieved market price. In this case, it will effectively receive gross income lower than under the previous regime.
It is to be taken into account that the ESF is a special entity created with the purpose of the settlement and management of the financial relations related to the promotional scheme for RES generated electricity and other sources (such as highly efficient co-generation). The funds managed by the ESF may not be subject to enforcement and the set-off of obligations of other entities to the ESF against receivables from the fund is prohibited by law. This creates potential risks for RES producers which are entitled to payments for premiums from the ESF. If, for any reason, the sources for funding the ESF are insufficient to cover its obligations for premiums to the RES producers, there will be not effective measures for RES producers to obtain payment and at the same time they will have to continue to make their 5% instalments to the fund.

Guarantees of origin

It should be noted that under the wording of the Renewables Act, the mandatory off-take obligation under the feed-in tariff regime or the obligation to pay premiums under the new premiums regime is conditioned on the issuance of the so-called guarantees of origin[9], issued by the SEDA on a monthly basis. The specific terms and conditions for issuance, transfer and cancellation of certificates of origin are set out in an ordinance of the Minister of the Economy and Energy. In general terms, each month a producer shall submit applications for issuance of guarantees of origin for the electricity produced during the previous month. In addition, reports for the electricity produced shall be submitted each quarter. This means that the relevant off-taker will be obliged to purchase and the ESF will be obliged to pay premiums for only the electricity for which a guarantee of origin has been issued. In this way the Renewables Act assigns an important role to such guarantees of origin (if for some reason the issuance of a guarantee of origin is refused or delayed, the project company will not be entitled to sell the electricity generated) and represents an additional administrative restriction for generation companies. This role goes far beyond the concept of Directive 2009/28/EC which envisages that such instruments will be only used for proving to final customers the percentage or quantity of energy from renewable sources in an energy supplier's energy mix in accordance with Article 3(6)

[9] As envisaged by Article 15 of Directive 2009/28/EC.

of Directive 2003/54/EC (i.e. they are not viewed as a condition for benefiting from the relevant encouragement system of obligatory purchase of electricity at preferential prices) and also that the issuance of such instruments will be only optional and at the request of the generation company.

Access to the grid

RES producers are entitled to priority access to the grid under the RES Act. At the same time, in order to account for the additional costs for ESO for balancing the national system which are generated by intermittent RES producers such as PV and wind facilities, the Commission introduces a special higher fee for access to the transmission grid for such producers. While for ordinary electricity generation facilities the amount of such a fee is BGN 2.12 / MWh (as of July 2019) the special access fee for PV and wind facilities is in the amount of BGN 5.14 / MWh.

7.2.4 Natural gas

Market overview

The Bulgarian natural gas market is still in the process of development and the share of the open market is negligible with 98.90% of the natural gas for local consumption in 2018[10] supplied by the state owned national supplier Bulgargas at regulated prices (the only source of supplies for Bulgargas being its long term supply contract with Gazprom, Russia). The remaining 1.10 % of supplies were realised by traders at free market prices.

The country has a well-developed gas transmission network (mostly built during the socialist era), which is operated by Bulgartransgas – a state-owned company, which is used for internal supplies to distribution companies, large industrial consumers and power plants as well as for transiting gas to Turkey, Greece and Macedonia and supplying. The system is currently underused (due to drastic decline of use of natural gas by industrial companies from the time when the system was built) - about 45 % of capacity of the national transmission system was used in 2018.

Currently, the system is fed almost exclusively with gas from Russia through the Ukraine under long-term supply agreements (local natural gas sources add negligible quantities to the system – less than 1 % as of the end of 2018).

Therefore, after the Russia-Ukraine gas crisis of 2009, which resulted in a cut of supplies to Bulgaria, the government intensified work on building interconnection lines with the systems of Romania, Serbia, Greece and Turkey. Projects for the construction of a terminal for liquefied natural gas ("**LNG**") or use of the existing terminal in Greece as well for supply of compressed natural gas ("**CNG**") from Azerbaijan across the Black Sea have been also discussed, although no practical steps for their implementation have so far been made.

A number of gas infrastructure projects involving the Bulgarian market have been included in the updated list of Projects of Common Interest (PCI) of the European Commission of November 2017.

The market is heavily dependent on imports from Russia which account for almost 99 % of local consumption as of 2018. In previous years local deposits have covered up to 10% of local demand but operating deposits are close to depleted. In 2011 the government granted a permit for exploration of shale gas to Chevron but in 2012 the Parliament imposed a moratorium on the use of "fracking" technologies in Bulgaria and Chevron suspended its activities in Bulgaria. A number of exploration operations in the Black Sea shelf are currently being conducted but far from commercial discoveries at this stage.

Regulatory overview

The natural gas sector is regulated by the Energy Act and a number of Ordinances and Rules issues on its basis by the Council of Ministers and the Commission. This legislation

[10] Data from the Annual Report of the Energy and Water Regulatory Commission of July 2019.

conforms to the fundamental EU guidelines in the sector. Among other things, the law provides for:

(a) the unbundling of services through the establishment of an independent system operator Bulgartransgas which undertook the transportation activities previously performed by the national supplier Bulgargas;
(b) the free development by private investors of transit and gas distribution networks and storage facilities under a licence;
(c) the liberalisation of supply;
(d) third party access to the national transportation system, including storage facilities, on the basis of tariffs approved by the Commission.

For a long time, the local regulatory framework allowing for an actual open market and choice of suppliers by customers was not developed which was a serious obstacle to effective development of free gas market (accompanied by the lack of choice of sources of gas and lack of interconnections). In 2013, on a complaint by one of the major local gas distribution companies, the European Commission opened a case against BEH and its subsidiaries Bulgargas and Bulgartransgas on allegations for hindering competitors from accessing key gas infrastructures in Bulgaria, in breach of EU antitrust rules. In December 2018 the European Commission issued a decision confirming the violations and fined the respondents EUR 77,068,000.

In the context of that procedure and forced by European Regulations for the internal gas market, the local Regulator intensified in the last years the process of preparation of new trading and balancing rules and such were adopted in 2015 and 2016 and substantially amended in 2019 allowing for effective opening of the market and trading.

As of July 2019, a Bill of amendments to the Bulgarian Energy Act was approved in the Parliament with the purpose of setting the legal framework for creating a licensed trading platform (exchange) for gas and assuring liquidity for the same.

Regulated natural gas market activities

According to the provisions of the Energy Act, the supply and distribution of natural gas, as well as the construction and operation of gas transit, transmission and distribution networks and gas storage facilities, are permitted after issuance of a respective licence, which is granted by the Commission.

No licence is required for trading with natural gas including for the import and export of natural gas and that sector is currently open to competition without regulatory barriers. This peculiarity of local regulatory framework is probably due to the marginal current share of the free market (about 1 % of total consumption) due to very limited sources of gas supply and lack of diversified cross-border transportation routes.

The licensing of an organised trading platform is envisaged by proposed changes to the Energy act of 2019.Only one licence for operation of the transmission network (high-pressure pipelines) and for public supply of electricity has been issued for the territory of Bulgaria. Bulgartransgas (under the control of the Bulgarian government) holds the licence for the operation of the national transmission network and Bulgargas (also controlled by the Bulgarian government) holds the licence for the public supply of gas. Bulgartransgas holds also the only currently effective licences for transit of natural gas and for operating a gas storage facility (Chiren).

Similarly, only one licence for operation of a distribution network and for supply of gas to end consumers has been issued for a particular licensed territory. Currently, 24 companies have been issued licenses for distribution of natural gas in regions comprising several towns or within the territory of individual towns.
In principle licences are issued on a "first come, first serve basis" provided that the applicant meets the relevant requirements for obtaining a licence. If there is more than one applicant interested in a particular territory, the Commission must organise a competition procedure for granting the licence.

The initial term of these licences depends on the licensed activity and is up to 35 years. Upon request of the licence holder, the licences may be renewed for the same time period.

Exploration and production

All underground natural resources including hydrocarbons are exclusive public state property. The state provides rights for prospecting and exploration on the basis of a special permit. Rights for the extracting of natural resources are granted by way of a concession. The intensification of local production of gas is one of the priorities of the Bulgarian government. Until now commercial exploitation of local deposits of gas has been modest and has represented less than 10 per cent of local consumption (mainly the Galata deposit, which has been operated since 2004 by Melrose Resources and is now depleted and in the process of being licensed as a gas storage facility).

In 2010 Melrose Resources (now Petroceltic International) received two new concessions for the exploitation of local deposits. As of 2018 however, the local production is marginal – in the range of 120,000 MWh (both for local consumption and exports) which is less than 1 % of local consumption.

The exploration of oil and gas deposits may be carried out only on the basis of an exploration permit issued by the Council of Ministers ("**CoM**") after a proposal by the Ministry of Energy. For that purpose, the CoM institutes a tender procedure and the bidder ranked in first place shall be granted an exploration permit with a term of up to five years (with an option for up to three extensions and the total duration of all extensions can be up to five years, i.e. maximum 10 years in total). Based on the exploration permit the respective bidder concludes an exploration agreement with the CoM outlining the terms and conditions for conducting exploration activities including minimum investments and business programme, fees payable to the government, etc. The exploration rights require its holder to register the geological discovery and commercial discovery of oil and gas deposits. The geological discovery reveals the quantities and qualities of the oil and gas of the respective deposit and the exact location of the deposit, while the commercial discovery contains technical and commercial evaluation of the deposit and proposed methods for extraction of the underground resources.

A holder of an exploration permit which has registered a commercial discovery and has obtained a certificate for that commercial discovery may submit an application to the government for direct (i.e. without conduction of any tender procedure) granting of oil and gas concession within six months as of the issue of the certificate for commercial discovery. If no certificate for commercial discovery has been issued upon expiry of the exploration permit or if the holder of the certificate does not apply for a concession within the 6-month term, the CoM will be free to issue a new exploration permit or an extraction concession for the respective territory following a tender procedure.

After the issuance of a decision of the CoM for granting the concession, the concessionaire shall conclude a Concession agreement for a maximum term of 35 years (which term may be prolonged with up to 15 years). During the concession the concessionaire has the right to extract and process oil and gas from the deposit and to sell the oil and gas products to third parties. The concessionaire is obliged to pay to the state a concession fee (the amount of which is to be determined in the concession agreement), to carry out the annual working programme and to re-cultivate the concession area after the conclusion of the extracting and processing works.

Transmission and access to the system

The national natural gas transportation system (high-pressure pipelines) consists of two independent balancing zones – the national transmission system which is predominantly used for supplies to the local market and the transit transmission system, which is predominantly used for transit of gas from the border with Romania to Turkey, Greece and Macedonia under long term supply contracts with Gazprom. The two systems have two interconnection points so physical exchange of gas between the two is possible. Both systems are owned and operated by Bulgartransgas. Bulgartransgas is also owning and operating the single local gas storage facility Chiren.

Currently, there are a number of exit/entry points to the national system: one exit/entry point from the Romanian transmission system supplying Russian gas through the Ukraine, the exit/entry point to the gas storage facility Chiren, an exit/entry point at the interconnector with Romania Rousse-Giurgiu (until certain improvements of the system on Romanian territory are made, as of 2019 the interconnector provides unidirectional transmission to Romania only) and two entry points connecting local deposits.

The transit system has the following interconnection points: one exit/entry point with the Romanian transmission system, an exit/entry point with the Greek transmission system and two exit points to the transmission systems of Macedonia and Turkey (in 2019 certain plans to refurbish the interconnection facilities with Turkey in order to allow for a reverse flow of gas were announced). As mentioned, a number of interconnection lines with the systems of neighbouring Greece, Turkey and Serbia are in process of development which will substantially diversify the transmission opportunities of the system.

By law Bulgartransgas and the licensed regional distribution companies are obliged to allow free and non-discriminatory access to the transmission systems to all users (consumers, traders, local producers and licensed owners of gas storage facilities) under terms and conditions established by Rules adopted by the Commission and pursuant to access agreements under general rules approved by the Commission. The fees for access and transmission are determined by the Commission. Access to the system may be refused only on technical reasons - lack of capacity or hazard to the integrity and security of the transmission system. Refusal for access on the basis of potentially serious economic and financing difficulties for another user of the system due to contracts containing 'take or pay' clauses is also possible, but only on the basis of an express derogation issued by the Commission, which must be notified to and is subject to control by the European Commission. The same obligation to provide access applies to the operators of gas storage facilities.

Trading and supply

The prices under which the public supplier of natural gas supplies the final suppliers and customers are approved by the Commission. The prices at which final suppliers supply protected consumers are also approved by the Commission and transactions are concluded under general terms approved by the Commission. All other transactions are concluded at market prices under Rules approved by the Commission. The transmission system operator (part of Bulgartransgas) is responsible for the balancing and administration of the transactions. Although in theory the market is fully liberalised, virtually all supplies to large consumers are performed by the public supplier Bulgargas with few deals realised between industrial consumers and the operator of local deposits and traders.

It is expected that the liberalised market will grow significantly in the next years. As of July 2019, a Bill of amendments to the Bulgarian Energy Act was approved the Parliament with the purpose of setting the legal framework for creating a licensed trading platform (exchange) for gas and assuring liquidity for the same.

LNG and storage capacity

There are no operating LNG terminals in Bulgaria. The government has discussed ideas for the construction of a local LNG terminal or signing arrangements for the use of the existing LNG terminal in Greece for supplies to Bulgaria, but no specific steps have been taken so far.

7.2.5 Upstream and the oil market

Market overview

Currently, the local production of oil in Bulgaria is negligible and virtually 100 per cent of oil is imported from Russia. In the last year the government has prioritised the exploration for local oil and gas deposits and has issued a number of explorations permits to international companies hoping to increase domestic production.

Regulatory overview

In respect of the legal regime for oil exploration and production, please refer to Section 4.4 above.

7.2.6 Forthcoming developments in the Bulgarian energy sector

Major investment opportunities are expected in the Bulgarian energy sector in the next years in many different areas.

Nuclear energy
The project for the construction of a new Belene NPP (two 1000 MW units) was officially restarted by the Bulgarian Government and Parliament in 2018 and in 2019 an international procedure for selecting a co-investor for the completion of the project was initiated. The project is expected to cost over EUR 10 billion and could reshape the local and regional electricity market.

Renewable energy
Investments in new project have been effectively halted in last years. However, there is quite active market for existing projects in operation and it may be expected that this market will further grow after the new promotional schemes introduced in 2018 and 2019 are tested and investors obtain actual data about how the project financials perform in the new environment. In the context of declining costs of renewable energy technologies and rising electricity prices and CO_2 emissions costs potential may appear for development of new projects without subsidies.

New gas burning co-generation facilities
Apart from certain district heating and industrial co-generation facilities there are no major local gas burning generation facilities. With Bulgarian coal power plants facing serious issues with CO_2 emission costs and increased restrictions for air pollutant emissions and the rising importance of natural gas as a transition fuel, opportunities are appearing for new gas burning generation facilities in Bulgaria particularly co-generation facilities for district heating or industrial purposes.

Electricity and gas markets liberalisation
The liberalisation of the local electricity and gas markets despite speeding up in last years is yet far from the level of matured markets. It is expected that measures for boosting free trade in both markets will continue which will bring significant opportunities for electricity and gas trading including cross-border.

Major gas infrastructure projects
Bulgaria has the chance to strengthen its position as a local energy hub. A number of gas infrastructure projects involving Bulgaria have been included in the updated list of Projects of Common Interest of the European Commission of November 2017.

Oil and gas
Further increase of local production of natural gas and oil is one of the priorities of the Bulgarian government in the aims of ensuring the security of ***supplies*** and a certain level of independence from imports of hydrocarbons. Therefore, the government continues to implement its plans to attract major investments by international companies in exploration activities.

7.2.7 Impact of the coronavirus pandemic on energy and infrastructure[11]

A. Covid-19 Response Investment and Support Initiative – General

EU Funding

In the context of the CRII Bulgaria is allowed to retain as immediate liquidity for Covid-19 response measures EUR 122 million of unspent pre-financing from the EU's cohesion funds and could benefit from EUR 690 million of co-financing from the EU budget if such unspent amounts are effectively used – i.e. a total of EUR 812 million as fresh money from the EU budget. In addition, Bulgaria would be allowed to reprioritise and use for Covid-19 response measures EUR 546 million of cohesion funds that have not been contracted for the budgeting period 2014-2020.

A state of emergency was introduced in Bulgaria by a decision of the Parliament of 13 March 2020 (originally with a duration until 13 April 2020, subsequently extended until 13 May 2020) and a special Act on the Measures and Actions during the State of Emergency was adopted on 23 March 2020, effective as of 13 March 2020 (the "State of Emergency Act"). The State of Emergency Act introduced certain general rules and amendments to national legislation on EU funds' spending which will be applicable during the duration of the state of emergency and which provide for flexibility and simplified rules for allocation of funds for Covid-19 response measures. In particular, grants can be awarded for eligible Covid-19 response measures without a prior invitation for collecting offers and/or under reduced time periods, with a simplified process for approval. There is, however, no public information so far on particular measures and programs made available by the government to the business in the CRII context. Funds have been so far allocated mostly to public entities for spending on health systems related measures (such as protective equipment and medical supplies, supplemental payments to health workers involved in Covid-19 response activities, etc.).

Covering of salary expenses

A general economic support measure to be made available in Bulgaria includes partial covering of salary expenses for employees of enterprises affected by the pandemic. Under that measure, for a period of up to three months, the National Social Security Institute will cover to eligible employers upon their request 60% of the amount of the individual social insurance income for January 2020 and the social security contributions due by the employer for certain of its employees, based on criteria adopted by the Bulgarian government.

According to a relevant Decree of the Council of Ministers, the possibility for companies to claim the above support is available for:

(i) employees whose work was suspended on the basis of government authority in relation to the state of emergency;
(ii) employees whose work was suspended on the basis of an order of the employer in relation to the state of emergency;
(iii) employees whose working hours have been reduced on the basis of an order of the employer in relation to the state of emergency.

The availability of aid is subject to a number of exceptions and conditions. The aid under item (i) above is available only to employers of certain sectors directly affected by governmental measures such as retail outlets, air and road transport, hotels and restaurants, cultural, sports and educational institutions, etc. The other types of aid are available generally to all economic sectors except for agriculture, forestry and fishery, financial sector, educational sector, health sector. The effective implementation of the measure will start upon state aid approval by the European Commission which is still pending.

Intermediated SME Loan Guarantee Program

The government injected BGN 500 million (EUR 255 million) as a capital increase of the state-owned Bulgarian Development Bank AD (the "BDB"). The BDB will use these funds to provide public guarantees on investment loans and working capital loans by private banks to

[11] The South East Europe Energy Handbook Special Edition "Overview of the Coronavirus Support Initiative & Impact on the Energy and Infrastructure Sectors in Southeast Europe", https://seelegal.org/see-legal-joint-publications/see-special-energy-handbook

micro, small and medium-sized companies affected by the Covid-19 outbreak in Bulgaria. The scheme aims at limiting the risk associated with issuing loans to those companies that are most severely affected by the economic impact of the current crisis. The measure has been cleared by the European Commission under EU State aid rules on 8 April 2020 and the BDB is to publish shortly the particular terms and conditions for the implementation of the measure.

Financing repayment moratorium

Under recent amendments to State of Emergency Act (effective as of 9 April 2020), the effects of a default on payments of private debtors under loan agreements or agreements for other forms of financings (factoring, forfeiting, etc.) provided by banks and financial institutions (including when the financing receivables have been transferred to other entities), as well as under lease agreements are suspended for the period of the state of emergency. This includes the accrual of interest and penalties for delay, acceleration, and the right to rescind a contract and repossess assets.

At the same time, in compliance with the Guidelines on legislative and non-legislative moratoria on loan repayments applied in the light of the Covid-19 crisis adopted by the European Banking Authority, the Bulgarian National Bank has approved general terms for a non-legislative (voluntary) bank loans repayment rescheduling schemes. Pursuant to the approved terms, banks that have declared to the BNB that they would join the scheme can agree with borrowers affected by the Covid-19 outbreak on the rescheduling of loan repayments (choosing from three types of rescheduling plans) for up to six months on loans contracted before 31 March 2020. So, rescheduled debts will not be considered as non-performing loans for banks' solvency purposes.

Tax measures

Under the State of Emergency Act, the deadlines for submission of returns and payment of certain alternative and one-off corporate taxes and local municipal taxes have been postponed to June 2020. The rules for advance corporate income tax instalments in 2020 have been revised to provide more flexibility to companies to account for the effects of the economic slowdown as a result of the Covid-19 outbreak. No new enforcement proceedings for tax and other public debts are to be initiated until the end of the state of emergency, subject to limited exceptions. All existing enforcement procedures are suspended, subject to limited exceptions.

B. Impact on the Energy and Infrastructure Sectors

No major regulatory changes have been introduced in the energy sector as a result of the Covid-19 outbreak in Bulgaria. The economic slowdown and the closure of many industrial and service provision facilities caused by the Covid-19 restrictions naturally affected the energy markets with electricity prices at the Bulgarian exchange dropping by about 30% in the last two weeks of March compared to the same period of 2019. However, the volumes of electricity consumption were only slightly affected and there were no major dropdowns in consumption like those recorded in some other European countries.

In view of the expected economic slowdown and for the purposes of public expenditures control and reprioritization, proposals on postponing certain large energy infrastructure projects such as the Belene Nuclear Power Plant project and the Balkan Stream gas pipeline project have been made public but for the time being no official position of the government has been made. In the meantime, the terms under the procedure for the selection of a strategic investor for the Belene NPP project have been suspended for the period of the state of emergency. It could be expected that the redirecting of grants from EU funds to Covid-19 related measures would affect the financing and implementation of large roads and other public infrastructure projects but no official data is available at this stage. In accordance with the State of Emergency Act, all electricity grid operators should discontinue all planned maintenance involving interruption of electricity transmission, with the exception of emergency repairs.

The periods for payment of electricity bills by household customers, as established in the approved general terms of the relevant suppliers, are extended from 10 days to 20 days and may be extended further by an order of the Minister of Energy upon recommendation of the national emergency committee after considering the impact on the financial status of electricity suppliers and the security of supplies.

All utility companies must operate their customer service centres in strict compliance with the relevant requirements of the national emergency committee. Employees of all utility companies traveling on business are exempted from travelling restrictions which are otherwise applicable under the relevant pandemic measures. All healthcare establishments, state institutions and companies in the telecommunications sector are required to make urgent preventive checks of their reserve electricity supply systems and capacities aimed at assuring uninterrupted electricity supplies for their operations and must inform the Ministry of Energy of the results, without delay.

7.3 CROATIA

7.3.1 Introduction to the energy market

Croatia has, within the past decade and especially in the past couple of years, seen vivid development of the energy sector, in all of its areas such as electricity and gas markets, renewables and upstream regulation and activities.

Legislative framework of the energy sector in Republic of Croatia ("**RoC**") develops in the direction set by the obligations assumed by international agreements in fields of energy, environmental protection and climate, by the ever-present obligation to harmonize Croatian energy legislation with the European acquis in this area, within the EU membership, as well as by the real need to regulate relations between energy market stakeholders in line with the demands of economic, energy, environmental and social policies at European and national level. Croatian energy legislation is continuously harmonized in line with the European acquis requirements, by updating its existing legislation, or by adopting new energy laws and regulations necessary for the transposition.

Apart from becoming a member of the EU internal energy market which to a certain extent applied even before the accession as a result of the Ratification and Accession Treaty signed in 2001, by ratifying the Energy Charter Treaty, Croatia has undertaken to comply with the principles of market economy in the energy sector, enhancing energy efficiency and environmental protection. Also, by ratifying the Kyoto protocol, it has undertaken to ensure that 20 per cent of all energy consumed in Croatia comes from renewable energy sources. Consequently, in the last few years Croatia has been experiencing development of renewable energy projects such as wind, solar and biomass power plants, etc. It's important to mention that Croatia's share of renewable energy sources already stands at 29% . Therefore, Croatia has exceeded the 20% target level in the total energy consumption, the European Union has set for 2020.

The energy sector is the largest source of greenhouse gas emissions, and climate change is one of the most important threats to modern mankind. Global challenges and instruments (like the United Nations Millennium Development Goals and Paris Accord) and EU policies (mostly in the energy Union framework) create the framework for the development of energy policies in Croatia.

Owing to the Paris Accord, global efforts are aimed at reducing greenhouse gas emissions, aiming to keep Earth's average temperature rise below 2° C and preferably below 1.5° C. Europe already has and wants to keep the leading role in the global climate change struggle, as a consequence thorough changes are needed within the energy sector. The Republic of Croatia, as an EU Member State, participates in the adoption and implementation of EU common policies, including the energy policy. The Ministry of Environment and Energy initiated the process of drafting the Energy Development Strategy of the Republic of Croatia by 2030 with a view to 2050 - an advisory document containing ideas, suggestions and possible directions for development of the energy sector. Said document serves to encourage debate and collect contributions from all stakeholders, a so-called Green Book. The premises, analyses and results presented in the Green Book constitute the basis for public discussion and rethinking of the changes that are taking place and will transform the energy sector and the use of energy in the coming decades. Changes are expected in the legal framework, sector structuring, business operations, system management, implementation of new technologies, construction of new infrastructure and strengthening the position of the end-users.

Ministry of energy, the regulatory agency and regulated subjects i.e. companies as service providers that were granted special position in the legal system of the Republic of Croatia ("**RoC**" or "**Croatia**"), constitute the unique institutional framework of the energy sector of RoC. These are as follows.

The central administrative body responsible for energy is the Ministry of Environment and Energy ("**Ministry**"), entrusted with activities of defining and implementing energy policy, strategic planning and development of the energy sector, security of energy supply in RoC, drafting legislative proposals and regulations in the field of energy, issuance of energy approvals, record keeping, supervision, international cooperation and representation of RoC in professional and advisory bodies in the EU as well as other professional and administrative activities. The Ministry was conferred with said activities by the Energy Act (Official Gazette No. 120/12, 14/14, 102/15, 68/18 of 27 July 2018) and accompanying sectoral acts and regulations.

The Croatian Energy Regulatory Agency ("**HERA**") is the body in charge of regulating all energy activities in Croatia and has its own budget, whose revenues consist of remuneration for conducting energy regulatory activities. HERA is established as an independent and non-profit legal entity with public powers for the purpose of determining and implementing the regulation of energy activities in the electricity, heating, gas and petroleum sectors. HERA is responsible to the Croatian Parliament by submitting a yearly report on its activities.

Croatian Agency for Mandatory Oil and Oil Derivatives Supplies ("**HANDA**") was merged into the Agency for Hydrocarbons ("**CHA**"), by Amendments and supplements to the The Petroleum and Oil Products Market Act (Official Gazette No. 19/2014, 73/2017 of 27 July 2018). CHA, as the central body in RoC for compulsory supplies of oil and oil derivatives, is the only body obliged and authorized to form, maintain and sell mandatory supplies of oil and oil derivatives.

The supplies are used in the case of certain disturbances in the market supply of oil and oil derivatives in RoC along with the fulfilment of RoC's international obligations, based on decisions of the International Energy Agency and the European Commission, to release compulsory supplies of oil and oil derivatives.

Croatian Energy Market Operator ltd. ("**HROTE**") provides public service of organizing the electricity and gas market, under the supervision of HERA.

[12] EUROSTAT

[13] HERA's primary activities are; issuance of licenses for carrying out energy activities, adoption of methodologies for the determination of tariff items in tariff systems, prescribing fees and supervision of their application, granting status of eligible electricity producers, approval of development and network construction plans, sectoral legislative activities, giving expert opinions or approvals for energy sector acts and regulations and supervising the work and quality of service provided by regulated subjects.

During the reconstruction of the Croatian power sector, Croatian Transmission System Operator ltd. ("**HOPS**") was established as an independent legal entity. HOPS is the only transmission system operator in RoC and the owner of the entire Croatian transmission network with the license to carry out energy transmission activities as a regulated public service.
Croatian Power Exchange ltd. ("**CROPEX**") is the central venue of organized electricity trading between market participants and stock exchange members, that assumes the risk of purchasing and selling electricity through closed stock exchange transactions.

HEP-Distribution System Operator ltd. ("**HEP ODS**") is a company within the HEP Group . HEP ODS has 21 distribution areas on the RoC territory. For the needs of network users, HEP ODS provides power distribution services that include network access and network usage. HEP ODS is responsible for the quality of the delivered electricity to all end customers and it guarantees steady supply electricity. It also conducts, maintains, builds and develops distribution network and ensures long-term network capabilities to meet future network access requirements.

HEP ELEKTRA ltd. is the only energy company authorized to provide public electricity supply services in RoC, for households as well as for business entities. It is a company within the HEP Group.

The Plinacro Group consists of: 1. PLINACRO ltd., the parent company, 2. Underground gas storage ltd., a subsidiary owned by the parent company since 2009 and 3. LNG CROATIA LLC, as a jointly controlled entity together with HEP d.d. PLINACRO ltd., as the operator of the gas transportation system in RoC, according to the provisions of the Gas Market Act (Official Gazette No. 18/18 of 23 February 2018), is responsible for the management, maintenance and development of the gas transportation system, all to ensure reliable and steady gas delivery.

In RoC, the activity of oil transportation through a pipeline is carried out by the Adriatic Pipeline d.d. ("**JANAF**"), which is obliged to provide access to the transportation system in an impartial and transparent manner to natural persons and legal entities, in accordance with the Petroleum and Oil Products Market Act (Official Gazette No. 19/4, 73/17 of 26 July 2017). In addition to oil transportation, JANAF's significant activities include; storage of oil and oil derivatives and transhipment of liquid cargo. The JANAF system was built as an international oil transportation system from Omišalj Port and Terminal, to domestic and foreign refineries in eastern and central Europe.

LNG CROATIA LLC is a company founded with the intent to build and manage the infrastructure necessary for the reception, storage and gasification of liquefied natural gas.

7.3.2 Electricity

Market overview

The performance of energy activities and the legal status and responsibilities of the participants in the electricity market are determined by the Energy Act (Official Gazette 120/2012, 14/2014, 95/2015, 102/2015, 68/2018 of 27 July 2018), ("**Energy Act**"), Electricity Market Act (Official Gazette No. 22/2013, 95/2015, 102/2015, 68/2018 of 27 July 2018), ("**Electricity Market Act**") and regulations adopted for their implementation.

Electricity Market Act distinguishes six types of energy activities within the electricity sector – production of electricity, transmission of electricity, distribution of electricity, organisation of electricity market, supply of electricity and trade of electricity. Only the energy operators holding energy licences

[14] Hrvatska elektroprivreda (HEP Group) is the national energy company, which has been dealing with generation, distribution and supply of electricity for more than a century. The parent company (parent body) of HEP Group is HEP d.d., which carries out the function of corporate governance of HEP Group and guarantees conditions for safe and reliable electricity supply to customers. Croatian transmission system operator (HOPS) has been unbundled from HEP Group, according to ITO model (Independent Transmission Operator).

issued by HERA are entitled to undertake the mentioned energy activities.[15]

As at 1 April 2019[16], the following market participants were registered as holders of energy licences for undertaking specific energy activities in the RoC[17]:

(a) for production of electricity – 55 different companies;
(b) for transmission of electricity – Hrvatski operator prijenosnog sustava d.o.o. – HOPS d.o.o., owned by HEP d.d., a 100 per cent state-owned company;
(c) for distribution of electricity – HEP-Operator distribucijskog sustava d.o.o. – HEP ODS, owned by HEP d.d.;
(d) for organisation of electricity market – HROTE;
(e) for electricity supply – 15 different companies;
(f) for electricity trading – 33 different companies;

All legislation within the energy sector was significantly changed in the period from 2014 to 2019, and further modification is expected to continue, since the energy sector represents the most important part of economic growth in the RoC.

The Croatian electricity market is only partially liberalised. Non-liberalisation exists, from both the legislative and market points of view, in relation to electricity transmission and distribution.

CROPEX was incorporated in May 2014 and become officially operational on the 10 February 2016. This represents a step towards the cooperation of the Croatian electric energy market with other markets in the area. It is also significant for the development of different cross-border transmission mechanisms. In June 2018, HOPS and CROPEX formally linked the Croatian electricity market to the European Multiregional Electricity Market, which was a first successful project of this kind for RoC. This was the very first introduction of the cross-border capacities with the ultimate goal to connect RoC with neighbouring wholesale electricity market.

Regulatory overview

Electricity Market Act secures implementation of the following directives in the Croatian legislative framework:

(a) Directive 2009/72/EC of the European Parliament and of the Council of 13 July 2009 concerning common rules for the internal market in electricity and repealing Directive 2003/54/EC;
(b) Directive 2009/28/EC of the European Parliament and of the Council on the promotion of the use of energy from renewable sources and amending and subsequently repealing Directives 2001/77/EC and 2003/30/EC; and
(c) Directive 2005/89/EC of the European Parliament and of the Council of 18 January 2006 concerning measures to safeguard security of electricity supply and infrastructure investment.

The Electricity Market Act secures implementation of the following regulations in the Croatian legislative framework:

(a) Regulation (EU) No 1227/2011 of the European Parliament and of the Council of 25 October 2011 on wholesale energy market integrity and transparency;
(b) Commission Regulation (EU) 2015/1222 of 24 July 2015 establishing a guideline on capacity allocation and congestion management;
(c) Commission Implementing Regulation (EU) No 1348/2014 of 17 December 2014 on data reporting implementing Article 8(2) and Article 8(6) of Regulation (EU) No 1227/2011 of the European Parliament and of the Council on wholesale energy market integrity and transparency.

[15] Certain exceptions do exist primarily in relation to the production of electricity wherein, in certain circumstances, legal or private persons will not be obligated to obtain the energy license. In addition, with respect to undertaking of some of the activities such as supply and trading, among other, additional requirements are to be complied with – obtaining of EIC sign – Energy Identification Coding Scheme, entering into an Energy balancing agreement with HOPS d.o.o., and other various agreements.

[16] Information is available on the HERA's website – https://www.hera.hr/hr/html/dozvole.html

[17] Wherever an energy activity is undertaken by more than three energy operators, only the number and not the names of such operators is given.

Apart from the Electricity Market Act and Energy Act, electricity activities in Croatia are mainly regulated by the following Croatian acts and regulations:

- Statute on Licences for Undertaking Energy Activities and Keeping the Registry of Issued and Revoked Licences for Undertaking Energy Activities (Official Gazette No. 88/15, 114/2015, 66/18) ("**Statute on Licences**");
- Act on renewable energy sources and high efficiency cogeneration (Official Gazette No. 100/15, 123/16, 131/17, 96/18, 111/18);
- Electricity Market Act (Official Gazette No. 22/13, 95/15, 102/15, 68/18);
- Act on Regulation of Energy Activities (Official Gazette No. 120/12, 68/18);
- Grid Rules of Transmission System (Official Gazette No. 67/17);
- Grid Rules of Distribution System (Official Gazette No. 74/18);
- Regulation on Issuing of Energy Licences and Determining the Conditions and Deadlines for Connecting on the Electro-energy Grid (Official Gazette 7/18);
- Methodology for Determination of Tariff Items for Guaranteed Supply with Electricity (Official Gazette No. 20/19);
- Methodology for Determination of Tariff Items for Supply with Electricity as Universal Service (Official Gazette No. 116/13, 38/14);
- Decision on Amount of Tariff Items for Guaranteed Electricity Supply (Official Gazette No. 25/19);
- Decision on Amount of Tariff Items for Distribution of Electricity (Official Gazette No. 112/18);
- Decision on Amount of Tariff Items for Transmission of Electricity (Official Gazette No. 112/18);
- Decision on Determining the Body Responsible for Coordination of Procedures for Issuing the Permits for Projects of Common Interest in the Energy Sector (Official Gazette No. 137/14, 31/17);
- Decision on Reimbursement for Renewable Energy Sources and High Efficiency Cogeneration (Official Gazette No. 87/17);
- Statute on Usage of Renewable Energy Sources and Cogeneration (Official Gazette No. 88/12, 120/12, 100/2015, 116/18);
- Decree on Incentives to Promote Electricity Production from Renewable Energy Sources and High Efficiency Cogeneration (Official Gazette No. 116/18);
- Decree on the Share of the New Electricity Delivered by Eligible Producers that the Electricity Suppliers are Required to Take Over from the Electricity Market Operator (Official Gazette No. 116/18);
- Statute on Acquisitions of Eligible Electricity Producer Status (Official Gazette No. 132/13, 81/14, 93/14, 24/15, 99/15, 110/15);
- Decree on Criteria for Obtaining Status of Vulnerable Energy Customers from Connected Systems (Official Gazette No. 95/15);

Regulated electricity market activities

The Electricity Market Act differentiates between the market-based and regulated energy activities. Regulated activities are undertaken as public services. Such activities are transmission and distribution of electricity, organisation of electricity market, which is undertaken by HROTE, and the supply of electricity in the amount and manner prescribed by the law. Other energy activities are performed as marked/based activities which are regulated by the market itself.

Material provisions of electricity market law and licensing regulations

The Statute on Licences regulates requirements which any energy operator undertaking an energy activity is obliged to meet. These requirements are specific to the type of energy activity. According to the Energy Act, all energy entities must meet the following requirements:

(a) be registered for undertaking the respective energy activity in theRoC;
(b) have sufficient technical qualifications for undertaking the subject activity;[22]
(c) prove employment of sufficient number of employees professionally qualified for undertaking of the subject activity;
(d) hold sufficient financial means necessary for undertaking of the subject activity or a proof of their capability to obtain one; [23]
(e) not to have any energy licence for undertaking of the subject energy activity revoked from the entity in the five years preceding the submission of the request;
(f) that the members of the management board or other responsible persons within the entity have not been convicted of a crime in an economic sector in the last five years, or that the natural person seeking the licence have not been convicted of a crime in an economic sector in the last three years.

[21] Croatian agencies and bodies competent for providing and regulating energy services issue publications with regard to the specific areas of energy services' provision (e.g. amount of tariff items, HOPS non-standard service fees, usage of the certain registries etc.). Such publications are regularly updated to be in compliance with the relevant legislation (e.g. the Energy Market Act).

[22] Specific technical qualifications are set forth for each type of energy activity with the Statute on Licences. This applies to the human resources and financial obligations requirements also.

[23] The energy licence holder (entity) needs to have sufficient financial means as determined by law or a proof of its capability to obtain such means in the following amounts: HRK 50,000 (approx. EUR 6,600) for production of electricity, HRK 300,000 (approx. EUR 39,500) for distribution, HRK 100,000 (approx. EUR 13,200) for transmission, HRK 20,000 (approx. EUR 2,650) for trade, and HRK 30,000 (approx. EUR 4,000) for supply of electricity.

Moreover, HERA may issue a licence to the entity which does not meet the aforementioned criteria if the entity is a holder of a project of a common interest, which has been listed on a list of projects of the common interest of the European Union.

Transfer of energy licence is regulated under the Statute on Licences. It stipulates the possibility to transfer the energy licence only in cases of spin-off of an energy licence holder, or its merger to or with another legal entity. In the event of spin-off and merger, the transfer of energy licence is possible to only one legal entity which is the universal successor of the energy licence holder in question, subject to the filing of the request for such transfer to HERA within the timelines specified in the subject statute.

Trading and supply of electricity

As previously mentioned, energy activity may be undertaken by a natural or legal person that has obtained an energy licence from HERA. Up-to-date practice of HERA was to issue energy licences only to those natural or legal persons registered for the undertaking of energy activities in the RoC (such registration in relation to the legal persons would imply a registration of undertaking energy activity as a business activity of such legal person in the court registry of the respective commercial court in the RoC).

In accordance with the new Electricity Market Act, the supplier or trader of electricity coming from the EU Member State or from the Energy Community member state wishing to participate in the electricity market of the RoC, as a supplier or trader, is also obligated to obtain respective energy licence from HERA. As of 2016 HERA may issue an energy licence to the trader or supplier of electricity coming from the EU and/or Energy Community member state under more simplified rules in line with the Statute on Licences. The logical interpretation of this provision would be that foreign entities from the EU and/or Energy Community member states will be allowed to undertake energy activities in the RoC subject to obtaining energy licence from HERA, without any type of establishment in the RoC. In line with the abovementioned, the Statute on Licences, allows HERA to issue a licence to an active trader from the EU and/or Energy Community without the need for establishing a branch office.

Therefore, the provisions of this statute enable foreign entities from the EU and/or Energy Community Member States to undertake energy trading activities in RoC without any type of establishment in the RoC, after obtaining a licence from HERA. Nevertheless, this provision may be in contradiction with the provision of the Croatian Companies Act (Official Gazette No. 111/1993, 34/1999, 121/1999, 52/2000, 118/2003, 107/2007, 146/2008, 137/2009, 111/2012, 125/2011, 68/2013, 110/2015 of 13 October 2010) according to which anyone who wishes to undertake permanent business activities in the RoC shall be obliged to establish a branch office at least. From HERA's publicly available registry, it seems that on the Croatian market there are indeed traders and suppliers with the registered seat in other countries in the EU and/or Energy Community.

Finally, according to the Electricity Market Act, the electricity market consists of retail and wholesale electricity market, whereas the wholesale market consists of "bilateral agreements market", "energy balancing market", and "electricity stock market". HROTE and HOPS are responsible for organizing the stock electricity market for physical trading with electricity on the whole territory of the RoC, and for the connection with other stock electricity markets. Croatian electricity stock market known as CROPEX is a central counter party (CCP) between the sellers and buyers of electricity.

The existing Croatian legislation differentiates between the electricity consumers entitled to choose their own supplier and paying the price of electricity determined by the market on the one hand, and the electricity consumers entitled to the electricity supply provided as public service, on the other hand. The "public service supply" is undertaken as regulated service, under the regulated prices. Furthermore, the Electricity Market Act differentiates between the (i) public service supply as universal service established for the need of households and the (ii) public service supply as guaranteed service which is, according to its statutory definition, applied when an end consumer, under certain circumstances, remains without a supplier.

According to the Electricity Market Act, the Government of RoC determines those energy operators that are (in line with the provisions of the Electricity Market Act) obligated to provide a service of electricity supply as universal service or as guaranteed supply on the territory of the RoC. Such energy operators are obligated to procure the electricity needed for a safe and continuous electricity supply from the producers, traders, other suppliers, and the organized electricity market or from import, wherein the priority is given to the electricity produced from renewable energy sources and cogeneration.

Transmission and grid access

There are only one transmission system operator and one distribution system operator in Croatia, respectively HOPS and HEP-ODS. They are a part of a vertically integrated company – HEP Group and are independent from one another with respect to their form, organisation and decision making.

One of the most important aspects of the transmission system is the execution of unbundling by choosing one of the possible models. Both the Directive 2009/72/EC and the Electricity Market Act recognize three types of models: ownership unbundling, ISO – Independent System Operator and ITO – Independent Transmission Operator models. The Croatian legislator has opted not to impose any of the models onto the transmission system operator but has rather left it to the vertically integrated company – HEP d.d., initial owner of the network system, to choose the model.

The grid connection agreement is concluded between the grid system operator and the producer of electricity in accordance with the Statute on Issuance of the Energy consents and Determination of Conditions and Deadlines for connection to the Electro Energy Grid. The connection fee is payable by the producer and covers the costs of the connection construction and securing of adequate technical conditions of the grid. The grid usage agreement is concluded between the grid system operator and the owner (or a holder of other in rem rights) of the building or a part of the building which is connecting to the grid. Such agreement governs the terms and conditions of the grid usage and is usually made for an indefinite time period.

General approvals and permits for electricity generation facility project implementation

There is a set of interdependent regulatory steps essential to the constructing and running of an electricity generation facility. Apart from the energy licence issued by HERA, each electricity generation facility construction also requires energy approvals (a requirement in addition to the regular construction-permitting process). Before obtaining the necessary approvals and licences, a new company has to be incorporated or the existing company's incorporation deed needs to be changed; in both cases, the generation of electricity as a business activity of the company must be registered with the court registry of the respective commercial court. Also, in the events of renewable electricity generation, the investor/project developer should choose the appropriate project site bearing in mind the investment feasibility with regards to the optimal usage of a specific RES, and difficulties regarding the grid connection, both of which depend on the location of generation facility. Also, the investor's decision on the location should be based on the respective construction possibilities provided for in the spatial plans, current land ownership status, as well as on other technical and economic factors.

Please note that the list of necessary licences and approvals will also include those approvals required for the renewable electricity generation facilities[24].

Licences and approvals

(a) Location permit is issued by the local government where the facility is to be constructed or by the Ministry of Construction and Spatial Planning (in case of a facility with more than 20 MW). Location permit is issued in cases such as those when construction is scheduled in phases (*fazna izgradnja*) and/or in stages (*etapna izgradnja*), or in case of unresolved property relations, or when expropriation is needed, etc.
(b) Securing the Grid Access – during the location permit issuing process, a grid connection agreement or pre-agreement is concluded.
(c) Energy approval – the energy approval is a requirement for the construction of the facility. It is a precondition for the issuance of the construction permit.
(d) Construction Permit – must be obtained within 2 years as of the validity of the energy approval.
(e) Preliminary Eligible Producer Status applies to renewable electricity generation facility and cogeneration heating plants only. IT (eventually) shall give its holder the right to a FiT price for produced electricity[25].
(f) Electro energy approval ("**EEA**") is a precondition for the grid connection of the generation facility.
(g) A usage permit is issued by the same body which issued the construction permit, once the construction is complete. It is a precondition for the usage of the facility. The usage permit confirms that the construction has been completed and that it fully complies with the construction regulation.
(h) The energy licence entitles its holder to undertake energy activities. It is issued by HERA which also keeps a registry of the issued energy licences.
(i) Eligible Producer Status ("**EP Status**") is preconditioned by the issuance of the energy licence, valid usage permit and grid usage agreement. When these are met and the EP Status is issued, the eligible producer may start engaging in market activities and collecting the FiT price for the power generated according to the FiT PPA with HROTE[26].
(j) Grid Connection is carried out by TSO or DSO, depending on the installed capacity of the facility. It is preconditioned by the completion of construction works, EEA, conclusion of the grid usage agreement and fulfilment of all obligations from the grid connection agreement

Forthcoming developments

Although RoC has made progress in the last couple of years in using the RES, there is still more potential to be exploited. It should be noted that Croatia is a sunny country with a desirable environment especially for wind and solar powerplants, but there is a lack of political will for certain changes. The last and certainly outdated energy development strategy was implemented in 2009.

In November 2018, the Energy Institute "Hrvoje Požar" published the new energy strategy called "Green Book," which represent a strategy until 2030 with a view to 2050. In one of the scenarios in the Green Book, it was envisaged that the increase in RES as a share of total energy consumption will amount to the required 32% in 2030 (as required by the Directive (EU) 2018/2001). While it was envisaged that the Green Book will be enacted in 2018., the newest anticipations suggest that the draft of the energy strategy will be held for a public hearing at the end of April 2019. On 24 December 2018, the Regulation (EU) 2018/1999 of the European Parliament and of the Council of 11 December 2018 on the Governance of the Energy Union and Climate Action entered into force.

[24] Usage of different renewable energy sources may require less (simple solar) or more (hydro) approvals to be undertaken.
[25] Please see Chapter 3.2 for further explanation on the PEP Status and the FiT PPA.
[26] For more information on the EP Status, please refer to Chapter 3.2 below.

The goals of the new regulation is to (i) to implement strategies and measures which ensure that the objectives of the energy union, in particular the EU's 2030 energy and climate targets, and the long-term EU greenhouse gas emissions commitments are consistent with the Paris agreement, (ii) to stimulate cooperation between Member States, (iii) to promote long-term certainty and predictability for investors, (iv) to reduce administrative burdens, and (v) to ensure consistent reporting by the EU and Member States. Also, according to the new rules laid out in the governance regulation, EU countries are required to develop national long-term strategies by 1 January 2020, and consistency between long-term-strategies and national energy and climate plans has to be ensured.

7.3.3 Renewable energy

Market overview

The Croatian Energy Development Strategy 2009 defines that the RoC has good natural conditions for the usage of RES and sets forth the following goals:

(a) fulfilling obligations from the 2009/28/EZ Directive on the promotion of the use of energy from RES in the amount of 20 per cent of direct gross energy consumption;
(b) securing that 10 per cent of energy consumed in transport comes from RES;
(c) ensuring that the electricity production from RES is at 35 per cent by 2020; and
(d) securing that 20 per cent for the gross direct energy consumption for heating and cooling from RES.

Apart from the Croatian Energy Development Strategy, the National Action Plan as of October 2013 ("NAP") to a certain extent sets out the development strategy differently than has been set out in the Energy Development Strategy 2009. According to the NAP, the goals to be achieved until 2020 are as follows:

(i) 39 per cent of RES in gross direct consumption of electricity;
(ii) 10 per cent of RES in gross direct consumption of energy for transport;
(iii) 19,6 per cent of RES in gross direct consumption for heating and cooling.[27]

The Energy Act as well as the Act on renewable energy sources and high efficiency cogeneration (Official Gazette No. 100/15, 123/16, 131/17, 96/18, 111/18) ("**Act on RES and CHP**"), determines that the usage of RES and CHP to be of interest for the RoC.

The Statute on the Usage of RES/CHP determines the plants and cogenerations which use RES, terms and conditions of their usage, and other matters of importance for using RES/CHP. This statute will remain applicable until the new one is adopted. The Registry for registration of the RES power plant projects (the "**RES Registry**") is kept by the Ministry. The Registry in fact shows the number of RES projects (and their respective capacity expressed in MWs) whose development has been initiated.[28] Nevertheless, the status of the RES Registry shows a great interest for the development of the RES projects in the RoC. Keeping in mind the aforementioned in 2.7, although Croatia meets its goals regarding share of renewables by 2020, there is a significant potential for continued integration of renewables which has not yet been used.

Support schemes

A system of incentives for the production of renewable electricity[29] was developed in 2007, and it has been conducted from 1 July 2007 until 31 December 2015 through the following feed-in-tariff ("**FiT**") systems:

1. The Tariff System for the Production of Electricity from Renewable Energy Sources and Cogeneration (Official Gazette No. 33/07);
2. The Tariff System for the Production of Electricity from Renewable Energy Sources and Cogeneration (Official Gazette No. 63/12, 121/13, 144/13);
3. The Tariff System for the Production of Electricity from Renewable Energy Sources and Cogeneration (Official Gazette No. 133/13, 151/13, 20/14, 107/14, 100/15).

[27] Discussed in Section 3.2 below.
[28] http://oie-aplikacije.mingo.hr/pregledi/.
[29] Renewable electricity is electricity produced from the RES.

On 1 January 2016, a new Act on RES and CHP has come into force and the previous FiT systems became inapplicable, except for those producers which have entered into a power purchase agreement ("**PPA**") with HROTE based on the FiT systems. Namely, there is no more guaranteed feed-in price for the purchase of power for 14 years by the HROTE. Instead of a guaranteed feed-in price, a new premium system has been adopted. This will include public tenders for the market premium and for the purpose of entering into a power purchase agreement with guaranteed purchase price. This will also apply to entering into a market premium agreement and power purchase agreement with guaranteed purchase price, instead of FiT PPA. However, all projects which have signed FiT PPA before 31 December 2015 are covered by the "old" FiT incentive scheme.

The newest amendments to the respective Act were made on 20 December 2018, which intensely changed the Act and upon which the Croatian government has passed new regulations[30]. The Incentives Decree specifies the manner and the conditions for the implementation of new incentive models by awarding the market premium or payment of guaranteed purchase price, determination of maximum reference values, determination of maximum guaranteed purchase prices, determination of incentive quotas, primary energy sources and similar.

This Incentives Decree determines the new rules of procedure from which HROTE will enter into PPAs from RES. Namely, such procedure is conducted through the public tenders for granting market premiums or through entering into an agreement with the guaranteed purchase price based on a decision on the best bidder. It is noteworthy that other prescribed and envisaged bylaws[31] have not been enacted in 2018, hence HROTE was not able to enter into new PPA from the RES.

Furthermore, producers of electricity and other persons which are performing activities regarding electricity production and which have a right to an incentive price in accordance to FiT PPA systems or a right to a guaranteed purchase price based on a PPA are included in the ECO balance group automatically in accordance to the Act on RES and CHP. ECO balancing group is run by HROTE as a separate activity from all other activities of HROTE. It is noteworthy that all producers are members of ECO balancing group regardless of when the PPA was entered into.

One of the biggest changes in the last several years in RES field is on the manner how balancing costs are paid. Previously, the balancing costs were paid in accordance to the FiT systems, while now it is determined by the Act itself. Regardless of whether the producers of energy entered into an agreement based on the FiT system or not, their rights and obligations are also regulated by the Act on RES and CHP. Thus said, the respective Act prescribes that HROTE is obliged to pay for the balancing costs from the funds collected on the basis of the incentive fees and from the monthly commission payable for each and every member of the ECO balancing group which connecting power is above 50 kW. A special regulation determines the amount of such monthly commission on an arbitrary basis.

7.3.4 District heating

Market overview

Energy activities within the heating sector in the RoC are production, supply and distribution of heating energy. While the production and supply of heating energy are undertaken as market activities, distribution is undertaken as public service. All energy entities operating in the district heating sector must obtain a licence for undertaking these activities from HERA

[30] Decree on Incentives to Promote Electricity Production from Renewable Energy Sources and High Efficiency Cogeneration (Official Gazette No. 116/18) ("**Incentives Decree**") and Decree on the Share of the New Electricity Delivered by Eligible Producers that the Electricity Suppliers are Required to Take Over from the Electricity Market Operator (Official Gazette No. 116/18) ("**Share Decree**").
[31] Decree on Quotas to Promote Electricity Production from Renewable Energy Sources and High Efficiency Cogeneration; State Aid Program

and must meet the requirements determined by the Ordinance on Licences for Undertaking of Energy Activities (Official Gazette No. 88/15, 114/15, 66/18).[32]

Data on energy operators undertaking one of the abovementioned activities is provided on HERA's website (www.hera.hr). As at 29 March 2019, 30 energy operators held energy licence for production of heating energy, 9 energy operators for distribution of heating energy, and 25 energy operators for supply of heating energy.

Energy operators which undertake energy activities of production, distribution and supply of heating energy are mostly owned by municipalities or the state; while a few of them are partially in private ownership.

As of 2012, due to the legislative changes, HERA is authorized to enact or approve prices, tariff systems and fees according to methodologies for production and distribution of heating energy. HERA adopted Methodology on Determination of Tariff Items for Production of Heating Energy (Official Gazette No. 56/14) and Methodology on Determination of Tariff Items for Distribution of Heating Energy (Official Gazette No. 56/14), which are used as basis for the adoption of decisions on the amounts of tariff items for distribution or production of heating energy with respect to the existing central heating systems.

Regulatory overview

The heating energy sector in the RoC was harmonised with the Third Energy Package, by way of adoption of the Heating Energy Market Act (Official Gazette No. 80/2013, 14/2014, 102/2014, 95/2015, 76/2018) and respective by-laws.

Heating Energy Market Act was used for the implementation of the following directives:

(a) Directive 2009/28/EC of the European Parliament and of the Council on the promotion of the use of energy from renewable sources and amending and subsequently repealing Directives 2001/77/EC and 2003/30/EC.;
(b) Directive 2010/31/EU of the European Parliament and of the Council of 19 May 2010 on the energy performance of buildings; and
(c) Directive 2012/27/EU of the European Parliament and of the Council of 25 October 2012 on energy efficiency.

The main legal act regulating heating energy market is the Heating Energy Market Act acting as an umbrella law for the heating energy sector in Croatia. It defines the conditions for the performance of production, distribution and supply of heating energy.

Legislative and regulatory framework of the heating energy market is comprised of the following legal acts:

- Energy Act (Official Gazette No. 120/12, 14/14, 95/15, 102/15, 68/18);
- Heating Energy Market Act (Official Gazette No. 80/2013, 14/14, 102/14, 95/15, 76/18);
- Act on Regulation of Energy Activities (Official Gazette No. 120/12, 68/18);
- Ordinance on Licences for Undertaking of Energy Activities and Registry for the Provided and Revoked Licences (Official Gazette No. 88/15, 114/15, 66/18);
- Ordinance on the Method of Allocating and Calculating the Costs of Supplied Heating Energy (Official Gazette No. 99/14, 27/15, 124/15);
- Methodology for Determination of Tariff Items for Production of Heating Energy (Official Gazette No. 56/14);
- Methodology for Determination of Tariff Items for Distribution of Heating Energy (Official Gazette No. 56/14);
- Methodology for Establishing the Fee for Connection to the Heating Distribution Network and for Increase in the Connection Capacity (Official Gazette No. 42/16);
- General Conditions for Supply of Heating Energy (Official Gazette No. 35/14);

[32] Certain exception with respect to the production of heating energy exists and relates to those production facilities whose capacity does not exceed 2 MW. This is also discussed in Section 4.3 below.

• General Conditions for Delivery of Heating Energy (Official Gazette No. 35/14, 129/15);
• Grid Rules for Distribution of Heating Energy (Official Gazette No. 35/14).

According to the Energy Act, all energy entities must meet the following requirements:

(i) to be registered for undertaking the respective energy activity with the court registry of the respective commercial court;
(ii) to have sufficient technical qualifications for undertaking the subject activity; [33]
(iii) to prove employment of sufficient number of employees professionally qualified for undertaking of the subject activity;
(iv) to hold sufficient financial means necessary for undertaking of the subject activity or a proof of its capability to obtain one;
(v) that no energy licence for undertaking of the subject energy activity has been taken away from the entity in the last five years prior to the submission of the request;
(vi) to provide a statement that the members of the management board or other responsible persons within the entity have not been convicted of a crime in an economic sector in the last five years.

The entity is also obliged to pay the fee for the issuance of the energy licence determined by the Decision on the Amount of the Fees for Undertaking Works of Regulation of Energy Activities (Official Gazette No. 155/2008, 50/2009, 103/2009, 21/2012). The fees are as follows: HRK 20,000 (approx. EUR 2,691.79) for the production of heating energy; HRK 15,000 (approx. EUR 2,018.84) for distribution of heating energy; HRK 10,000 (approx. EUR 1,345.89) for heating energy supply. Energy operators are also obliged to pay a fee to HERA for its work related to the regulation of energy market. The fee equals to the amount of 0,05 per cent of the total annual profit made out of sale of goods and services while undertaking respective registered energy activity in the preceding year.

Please note that the applicable Croatian energy legislation does not set forth specific legal rules on the minimum share capital or share transfer restrictions different from the general corporate rules regulating the same issues.

The issued energy license determines the period of its validity which can be extended if an application is made three months prior to its expiry. HERA is entitled to revoke the energy licence on a temporary basis if the energy operator no longer fulfils the conditions of technical qualifications and competencies, financial or any other conditions pursuant to which the licence to perform energy activities had been issued. Transfer of energy license is regulated under the Ordinance on Licences for Undertaking of Energy Activities and Registry for the Provided and Revoked Licences. The aforementioned Ordinance stipulates the possibility of the transfer of the energy license only in cases of spin off of an energy license holder, or its merger to or with another legal entity. In the event of spin off and merger, the transfer of energy license is possible to only one legal entity which is the universal successor of the energy license holder in question, subject to the filing of the request for such transfer to HERA within the timelines specified in the subject Ordinance.

Finally, the Heating Energy Market Act recognized the buyer of energy who is different from the end consumer and the supplier. The buyer is a legal or natural person who, in the name and on behalf of the owners and/or co-owners of a building which comprises of more than one individual usable units, buys (i) fuel for production of heating energy in the self-supported heating system (Cro. *samostalni toplinski sustav*); or (ii) heating energy from the supplier of heating energy in a closed (Cro. *zatvoreni toplinski sustav*) or central (Cro. *centralni toplinski sustav*) heating systems. Each such legal or natural person must be registered with the registry of buyers of heating energy kept by HERA.
